London, Ont.—The erection of a new city hall is contemplated.

London, Ont.—The ratepayers will vote on the advisability of erecting a memorial hall immediately west of the armories. City clerk, S. Baker.

Manyberries, Alta.—Tenders will be received until noon, September 27th, by Delayed school district No. 3764, for construction of frame school building. A. Brand, secretary-treasurer.

Mimico, Ont.—As a result of a series of conferences between the Goodyear Tire and Rubber Co. and the Mimico Housing Commission, 20 new brick houses will be built under the provincial scheme on Murrie St., and tenders will be called for immediately. The launching of a more comprehensive programme along similar lines is being contemplated for 1920.

Moncton, N.B.—A movement is on foot here for the erection of a home for girls.

Moose Jaw, Sask.—The contract for a three-story and basement office building, 40 by 80 feet, for the Robin Hood Mills, to be erected on High Street and Fifth Ave. West, and costing $50,000, has been let to A. E. Hamilton, Moose Jaw. The building will be of reinforced concrete construction.

New Westminster, B.C.—School board will request school boards and councils of all municipalities to unite with them in requesting Dominion government to establish technical schools under their plan, which provides for expenditure of $10,000,000 in the next ten years, to be allotted to the various provinces on basis of population, each province to contribute dollar for dollar with the Dominion. S. Bowell, chairman. J. D. MacLean, minister of eduction.

North Sydney, N.S.—Hospital board will construct extensions to, and remodel part of the present Hamilton Memorial Hospital buildings. W. S. Thompson, secretary.

Orillia, Ont.—Tenders will be received up to noon, September 26th, 1919, by Eustace G. Bird, architect, 6 King St. West, Toronto, for the several works required in the erection and completion of a semi-fireproof hospital building. Plans and specifications may be obtained at the office of the architect, and also from the chairman of the Hospital Board, Geo. Thomson, Orillia.

Ottawa, Ont.—The first contract for the building of dwelling houses on the Lindenlea property of the Ottawa housing commission has been let. This contract calls for the erection of ten houses. Other contracts may be announced shortly. Altogether there are 168 houses to be built.

Saskatoon, Sask.—Tenders will be received by the University of Saskatchewan, Saskatoon, up to September 20th, 1919, for all the work and materials for the electrical work on the Physics Building and extension to the Engineering Building. Plans and specifications may be seen at the University and at the office of Brown and Vallance, architects, Montreal.

Selkirk, Man.—The town council is planning to build a new collegiate, to cost approximately $30,000. The plans call for a brick building.

Sherbrooke, P.Q.—Among the contracts recently received by the MacKinnon Steel Co., Ltd., are the following: Structural steelwork for Belding Paul Corticelli Building, St. John's, P.Q., general contractor, Anglins, Norcross, Ltd., Montreal; steelwork for St. Augustine's Church, Cote St. Antoine Rd., Montreal, general contractor, M. J. Stack; steelwork for extension to Dominion Tire Factory, Kitchener, Ont., general contractor, Atlas Construction Co., Montreal; superstructure for 200-ft. span bridge to be erected on the East Branch of the River Yamaska; superstructure for 215-ft. span bridge to be erected over the Riviere Noire, municipality of St. Valerien, Shefford Co., P.Q. This company are also fabricating steelwork in connection with an extension to their own office, for which the general contractor is the Sherbrooke Construction Co.

St. John, N.B.—City Engineer G. N. Hatfield submitted a report to the city council on repairs necessary to the exhibition buildings estimated to cost $20,000.

St. John, N.B.—The Corona Candy Co. is planning to enlarge its plant.

St. Mary's, Ont.—At the January elections the ratepayers will vote on a by-law to provide for the erection of a Great War Veterans' club house. Clerk, Thos. M. Clark.

Swan River, Man.—The municipality is advertising for tenders for the erection of a hotel.

Sydney, N.S.—Contracts have been awarded by the C.N. Ry. for construction of a modern coaling plant to Bate and McMahon. Construction of general stores building to Chappel Bros.

Sydney, N.S.—The Nova Scotia Steel and Coal Co. will erect a by-product plant in the near future to cost over $2,000,000. The plant will be erected in connection with the company's works at Sydney Mines. The erection of the new ovens will mean a further enlargement of the present plant and the necessity for the erection of an additional blast furnace, which will cost another $1,500,000.

Three Rivers, Que.—A large plant will be erected here immediately. Lava Cement, Clay and Silicate Products Co.

Timmins, Ont.—Arrangements for laying out a townsite are being made at the Davidson Consolidated Gold Mines, and a church and school will be built in the near future. It is also the intention to build about 40 cottages, and an addition to the mill.

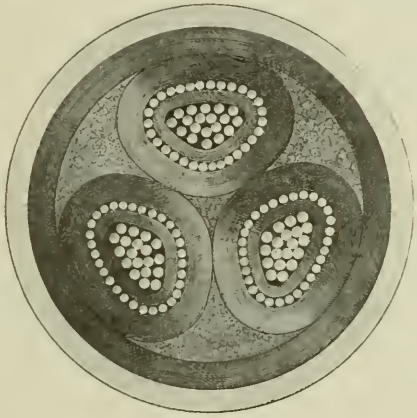
Toronto, Ont.—The police commissioners contemplate enlarging the present station building on Keele St., West Toronto.

Toronto, Ont.—Board of Control approved the expenditure required for new public libraries in Earlscourt and East Toronto.

Toronto, Ont.—City council decided to spend $110,000 on the erection of a stadium at the old Rosedale lacrosse grounds.

Toronto, Ont.—J. J. McLaughlin, Ltd., will construct alterations and additions to factory, 145 Sherbourne St. Estimated cost, $16,000.

SPLIT-CONDUCTOR CABLES



250,000 C.M. 3-CONDUCTOR 13,200 VOLT
PAPER-INSULATED, LEAD COVERED CABLE

Eugene F. Phillips Electrical Works, Ltd.

MONTREAL

Branches: Toronto, Winnipeg, Regina, Calgary, Vancouver

Toronto, Ont.—The Home Bank of Canada will construct a branch bank building on Danforth Ave., corner of Main St. Estimated cost, $20,000.

Toronto, Ont.—The Anchor Cap Co., Brooklyn, have commenced construction of a concrete and brick factory on Wallace Ave. Estimated cost, $45,000.

Toronto, Ont.—A by-law authorizing the issue of debentures to the value of $509,000 for the enlargement of public schools was passed by the city council last week.

Toronto, Ont.—Permit has been received by J. and J. Allen for construction of new Allen theatre at corner of College St. and Dovercourt Rd. Estimated cost, $100,000.

Toronto, Ont.—New tenders will be invited for some of the trades involved in the erection of certain schools, including the Norway School addition.

Toronto, Ont.—Quaker Candy Co. have obtained a permit for an addition to their factory at 420 Queen St. at a cost of $18,000.

Toronto, Ont.—Norcross Bros., the original builders of the Technical School, under the supervision of the architects, Ross and Macdonald, will make repairs to the stonework in the two turret towers, which have become necessary. Estimated cost, $12,000.

Toronto, Ont.—A banking and office building will shortly be erected by the Imperial Bank of Canada on the south-west corner of Kingston Rd. and Balsam Ave.

Toronto, Ont.—The Canadian Bank of Commerce will erect a new branch bank building on the south-west corner of Coxwell and Danforth Aves.

Toronto, Ont.—The Imperial Oil Co. have awarded contract for gasoline service station, corner Bloor and Howland Ave., to John V. Gray Construction Co., Ltd., 625 Confederation Life Building, Toronto.

Vancouver, B.C.—A permit for the construction of a garage at 1140 Georgia St. West has been taken out by R. J. Snelgrove. Estimated cost, $10,000.

Vancouver, B.C.—A by-law will be submitted to the ratepayers this month, providing for the expenditure of $200,000 on a technical college in this city. City clerk, W. McQueen.

Vancouver, B.C.—It is understood that a plant to manufacture and assemble marine machinery will be located on Burrard Inlet on water frontage adjoining P. Burns' packing plant. Estimated cost, $1,000,000.

Vancouver, B.C.—The Gregory Tire and Rubber Co., Ltd., of Akron, Ohio, are having plans prepared for the first unit of the large factory which they propose to erect. The building will probably be two stories of reinforced concrete construction, 200 ft. by 80 ft.

Vancouver, B.C.—The Allen Theatre Co., of Toronto, will erect a theatre in this city.

Walkerville, Ont.—The town council has voted to borrow from the Ontario Government $1,000,000 to relieve the housing shortage in the community.

Waterloo, Ont.—A movement is on foot by the county council for the construction of a new building for the Old People's Home.

Waterloo, Ont.—One hundred houses will be constructed by the Dominion Tire Co., acting in agreement with the council under the Federal housing scheme.

Weston, Ont.—The Canada Cycle and Motor Co. have awarded John V. Gray Construction Co., Ltd., 625 Confederation Life Building, Toronto, the contract for an extension to their factory.

Windsor, Ont.—The Separate School Board have awarded contracts for St. Edmund's, St. Joseph and Sacred Heart Schools to John V. Gray Construction Co., Ltd., 625 Confederation Life Building, Toronto.

Windsor, Ont.—Tenders are being called by the Imperial Bank of Canada for the erection of a reinforced concrete building at the corner of Ouelette Ave. and London St. Head office, Toronto.

Winnipeg, Man.—The Red River Paper Mills, Ltd., have been granted a charter by the provincial government, and will probably construct a new mill soon.

Winnipeg, Man.—The Leslie warehouse on Assiniboine Ave. is to be converted into a salesroom and garage for the Chevrolet Motor Sales Co. at a cost of $23,000. A permit has been taken out by J. McDiarmid. The interior of the Salvation Army citadel on Rupert St. is to be remodelled at a cost of $10,000.

Winnipeg, Man.—New exhibition buildings may be erected here. City engineer, W. P. Brereton.

Winnipeg, Man.—The Board of Governors of the University of Manitoba will urge upon the government the immediate necessity of the erection of a new university.

York Tp., Ont.—On September 2nd the township council passed a by-law providing for the issue of debentures to the amount of $60,000 for an 8-roomed addition to Secord Ave. School, S.S. No. 26. Township clerk, W. A. Clarke, 40 Jarvis St., Toronto.

Yorkton, Ont.—Application for the incorporation of the Yorkton Curling and Skating Co., Ltd., has been approved by the Local Government Board. It is the intention of the company to erect at Yorkton a large modern rink at a cost of approximately $20,000. The contract for the building will be awarded shortly.

MISCELLANEOUS

Balcarres, Sask.—Extensions are planned for the rural telephone system. Wm. Penny, Balcarres.

Calgary, Alta.—The Alberta Stockyards Co., Ltd., have commenced construction of enlargements and other improvements. A new office and administrative building will be commenced immediately. Estimated total cost, $300,000. J. M. Cameron, president.

Cardinal, Ont.—A survey is being carried out by government for a new canal which is being projected to take the place of the present system of canals extending from Cardinal to Cornwall.

Edmonton, Alta.—The city commissioners have instructed City Engineer A. W. Haddow to call for tenders for the construction of the sewer for the Swift Canadian packing plant and for the excavating work for the new telephone building.

St. John, N.B.—The Federal Department of Public Works will, at an early date, call for tenders for the extension of the grain conveyer system to Berth 15, and for dredging in the harbor, preparatory for next winter's business. Secretary, R. C. Desrochers, Ottawa.

Fredericton, N.B.—Tenders will be received until noon, September 19th, by the city council, for construction of a coagulating basin at the pumping station. G. R. Perkins, city clerk.

Grand Coulee, Sask.—The Adams Rural Telephone Co. contemplate extensions to their system. Estimated cost, $3,200. N. C. Draper, secretary-treasurer.

Moose Jaw, Sask.—Contract has been awarded by city council to Gorman, Clancy, Grindley Co., for a half million-gallon centrifugal pump for the Britannia Park water extension scheme. Contract price, $1,151 f.o.b., Moose Jaw.

Notre-Dame des Sept Douleurs, Que.—Tenders will be received by the department of public works, Ottawa, until noon, October 2nd, for construction of extension to wharf. plans, etc., offices of district engineers, post office building, Montreal, and at post office, Notre Dame des Sept Douleurs, Que. R. C. Desrochers, secretary.

Perley, Sask.—Contracts will soon be awarded for construction of 23 mls. of telephone in townships 22 and 23, range 2 west of 2nd meridian.

St. Laurent, Orleans, Que.—Tenders will be received until 12 o'clock noon, October 2nd, by the department of public works, Ottawa, for construction of wharf at St. Laurent, Island of Orleans, Montmorency County, Que. Plans, etc.,

JUST OUT!

Forest Products Their Manufacture and Use

By Professor NELSON C. BROWN, B.A., M.F., The New York State College of Forestry at Syracuse University ; Trade Commissioner, United States Lumber Trade Commission to Europe, Department of Commerce, Washington, D.C.

This book embraces the principal commercial features in the production, manufacture and utilization of the most important forest products other than lumber, in the United States.

The information given is presented in a brief, readable, and easily understood manner. The book as a whole fills a gap in the existing forestry literature on the principles and practices followed in the production of materials, which, from the viewpoint of invested capital and value of products, are of greater importance, collectively, than lumber.

There are many engineers who could use this book with profit, and it should be examined with a view to its adaptability to their work.

xix + 471 pages. 6 by 9. 120 figures. Cloth, $3 75 net.

Mechanical Properties of Wood

By SAMUEL J. RECORD, M.A., M.F., Assistant Professor of Forest Products, Forest School, Yale University.

A very helpful book for engineers, treating on the various strength values of many of the important American woods ; the methods of timber testing for the most part followed by the U.S. Forest Service, and other important subjects.

The mechanics involved are reduced to the simplest terms and without reference to higher mathematics.

xi + 165 pages. 6 by 9. 52 figures, 22 tables. Cloth, $1.75 net.

Send TO-DAY for copies on approval

ON APPROVAL OFFER

If cash accompanies your order, we will forward copies of any of these books on ten days' approval. If they should prove unsuited to your needs we will refund your money, provided the books are returned within ten days after their receipt.

offices of district engineers, post office building, Quebec, Que., Shaughnessy building, Montreal, and post office at St. Laurent d'Orleans, Que. R. C. Desrochers, secretary.

Sydney, N.S.—Work on a $5,000,000 drydock for Louisburg harbor will begin by the first of 1920, according to a statement recently made by J. W. Maddin, one of the incorporators of the Louisburg Drydock and Shipbuilding Co. Plans and specifications for the drydock have been completed and placed before the Federal Government for approval.

Sydney, N.S.—City council will shortly float bonds to the amount of $5,000 to secure funds for necessary water extensions and street construction. Acting city engineer, P. McKinnon.

Three Rivers, Que.—Contract has been awarded by the department of public works, Ottawa, to Simpson Bros., Ltd., Montreal, for dredging of St. Maurice river at Three Rivers. Contract price, $30,480. R. C. Desrochers, secretary.

Vermilion, Alta.—The bill authorizing the town council to borrow $29,000 for the purpose of erecting a new fire hall, purchasing additional equipment for the fire department and installing five underground tanks for fire protection has been passed. Secretary-treasurer, H. P. Long.

White Point, N.S.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Wednesday, September 17th, 1919, for the construction of an extension to the breakwater at Scotch Cove, White Point, Victoria County, N.S. Plans and specification can be seen at the Department of Public Works,; at the offices of the District Engineers at North Sydney, N.S.; Halifax, N.S., and at the post-office, White Point, N.S.

Tenders Called For

UNITY, SASK.

Sealed Tenders registered and endorsed on the envelope, Tenders for (tender bid on) and addressed to J. M. Jensen, Secretary-Treasurer of the Town of Unity, Sask., will be received up to 6 p.m., October 15th, 1919, for the supply, delivery and erection of the following machinery and materials and for the performance of certain works:—

Tender A. For the supply, delivery and erection of one internal combustion engine.
Tender B. For the supply, delivery and erection of one generator excitor, switch-board, transformers, meters, etc.
Tender C. For the supply and delivery of one oil storage tank.
Tender D. For the supply and delivery of pole, wire and line material.
Tender E. For the erection of electric pole line.
Tender F. For the erection of Power station and cooling chamber.

Marked cheque for five per cent. (5%) of the amount of the bid must accompany each tender.

Complete sets of plans and specifications may be seen at the office of the Consulting Engineers, Saskatoon, at the Secretary-Treasurer's office, Unity, Sask. Specifications on tenders A., B., C. and D. may be seen at the office of *The Canadian Engineer*, Winnipeg and Toronto, and the Contract Record office, Montreal.

HANLEY, SASK.

Sealed tenders, registered and endorsed on the envelope, Tenders for (tender bid on), and addressed to A. Holm, Secretary-Treasurer of the Town of Hanley, Sask., will be received up to 6 p.m., September 24th, 1919, for the supply, delivery and erection of the following machinery and materials and the performance of certain works:—

Tender A—For the supply, delivery and erection of one internal combustion engine.
Tender B—For the supply, delivery and erection of one generator, excitor, switchboard, transformers, meters, etc.
Tender C—For the supply and delivery of one oil storage tank.
Tender D—For the supply and delivery of poles, wire and line material.
Tender E—For the erection of electric pole line.
Tender F—For the erection of Power station and cooling chamber.

Marked cheque for five per cent. (5%) of the amount of the bid must accompany each tender.

Complete sets of plans and specifications may be seen at the office of the Consulting Engineers, Saskatoon; at the Secretary-Treasurer's office, Hanley Sask. Specifications on tenders A, B, C and D may be seen at the office of *The Canadian Engineer*, Toronto; *The Canadian Engineer*, Western office, 1206 McArthur Building, Winnipeg, and Contract Record office, Montreal.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Protection of Owners on Cost-Plus Contracts

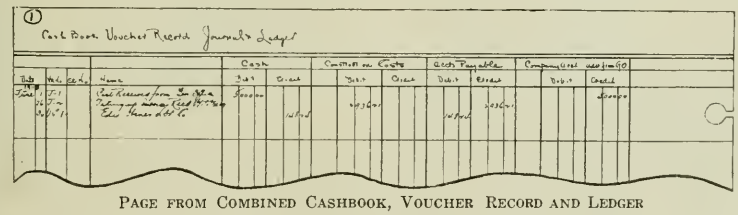
Practical Use of Dewey Decimal System in Keeping Books on the Job—Open for Inspection by Owners and Their Engineers and Architects—Distribution of Accounts—Classification of Plant Expense and Field Overhead

By F. A. WELLS

Vice-President, Wells Bros. Construction Co. of Canada, Ltd.

NO contractor who values his capital can afford to do without adequate cost records, both as a check on the job in progress and as a basis for future estimating. Yet the simpler that system of accounting, the better, and any refinements further than those necessary to give the actual required data are a waste of time and money. Some contractors keep their books under their hats or in their left-hand pocket of their coats, where all invoices go preparatory to paying. At the opposite extreme are firms who maintain a complicated system of accounts, both at the job and at the home office. Accounting methods sufficient for the lump-sum contract may be insufficient for the cost-plus-fixed-fee contract, under which the owner and his engineers and architects must have access to the accounts at all times.

The following system has been found adequate for cost-plus jobs, and with only a few changes this is the system put into effect on such typical work as that which we have done during the last few years for The Robert Simpson Co., Ltd., Toronto, and for the William Davies Co., Ltd., Toronto.



PAGE FROM COMBINED CASHBOOK, VOUCHER RECORD AND LEDGER

Occasionally we have found an owner who prefers to be given such data as will permit his own accountants to keep a complete system of books. Generally however, our accounts, kept on the job and open at all times for inspection, are considered sufficient, in view of the detail statements we render to the owner every two weeks, bearing the approval of the owner's representative, who is designated for that purpose. We urge owners to have their auditors frequently make examinations of accounts for their own satisfaction.

The system we are now using is briefly the keeping of:—(1)—Cashbook, voucher record and ledger, combined; (2)—Invoice and payroll register, combined; (3)—Detail cost record; and (4)—Accounts payable record (vendors' accounts).

The cashbook, voucher record and ledger is used for the recording of all cash received, cash disbursed by voucher and all journal entries.

The invoice and payroll register is used for the recording of all invoices and payrolls. The invoices and payrolls are numbered consecutively. This register has columns for date, invoice number, vendor's name, total amounts (both debit and credit) and individual columns for the 20 main accounts used in distribution of costs. The register represents an absolute detail control of all approved charges to the job, as only audited and approved items are given a register number or entered. The payrolls are given register numbers and approved the same as invoices. The office copies of all invoices are filed in numerical order in an ordinary letter file drawer, and bound in numerical order, in lots of 50 to 100, using an ordinary heavy file folder for cover, clamping the invoice to the folder.

The detail cost record is used for recording in detail the distribution of costs among the main accounts as shown on invoice register.

The accounts payable (or vendors' accounts) record is used for the recording of all invoices from vendors. After the invoices have been entered in the invoice register and detail cost record book, they are entered as a credit to vendor in accounts payable. Each vendor has a separate page or sheet. After entry is made, it is placed in file under vendor's name until ready for payment. When payment is made, same is vouchered and charged to accounts payable (vendors' account) and cash credited.

Issuance of purchase order (in quadruplicate).—The original of order is sent to vendor, the duplicate is filed numerically (which forms order register), triplicate is filed in open order file (vendor's name order), and quadruplicate (which forms material receipt or tally sheet) is filed by the office material clerk awaiting receipt of material.

Receipt of material.—Upon receipt of materials, the office material clerk checks and signs the material receipt portion of the order and files completely with supporting delivery tickets, etc., awaiting invoices.

Checking and auditing invoices.—Invoice upon receipt is checked against material receipt or tally sheet for receipt of material. Extensions, prices and footings are checked and certified. Cost distribution is checked and entered. Invoice is then audited for discount and cost distribution and certified. Invoice then passes to the superintendent for his approval and the approval of the owner's representative.

Entry of approved invoices in invoice register and vendor's account.—Upon return of approved invoice from the superintendent, the bookkeeper gives the invoice numerical register number and enters in the invoice register. Only fully approved invoices are given register number. Invoice is then posted to the credit of the vendor in accounts payable account and are charged in the detail cost record.

Journalizing accumulated totals of invoices registered to ledger.—Accumulated totals in the invoice register are journalized in the ledger (which is also the voucher record)

at daily, weekly or semi-monthly periods as is found practical.

Voucher check.—We have found the voucher check system to be the most convenient. The voucher is made in quadruplicate at the construction office on the job and the approval of the owner's representative is often indicated on all copies of the voucher. The check, or original voucher goes to the vendor, the duplicate to our general office for our records, the triplicate is kept as the job record and the quadruplicate is the "owner's copy," which is forwarded to the vendor with original to be receipted by him and returned. At intervals we furnish the owner with statement showing vouchers paid and receipted vouchers attached.

Since the major purpose of cost accounting is to give an adequate basis for future estimating, it is important that so far as practicable the form of cost accounting shall follow the form of estimate. This is not practicable to the last subdivision of each of the general accounts, but sufficient to permit intelligent use of all cost figures. With such figures it is possible to compare not only final costs, but costs at any stage of the job, with the original estimated cost for that portion of the contract. We frequently divide our estimate by floors, in the case of a many-storied building, in order to have a check upon quantities and upon expenditure at several stages of the work.

Distribution of Accounts

We use the decimal system of classification of accounts. The classifications number 100 to 600 inclusive and 900 are for our general books, which embrace the assets and liabilities, revenues and income accounts (we will omit these in our discussion). The general distribution is under the following headings:—

710 Excavation	810 Field overhead
720 Caissons	820 Extra work
730 Footings	830 Subcontracts
740 Trench and wall	840 (Subcontract) extra work
750 Concrete and fireproofing	
760 Masonry	850
770 Carpentry	860
780	870 Repair contracts
790	880
800 Plant expense	890 Company expense (not chargeable to owner)

The sub-divisions of headings 710-790 are between the items labor (1), material (2), and liability insurance (3). Thus labor in excavation would be 711, material in excavation 712 and liability insurance in excavation 713. A further division of the various kinds of labor and materials is made. The following classifications illustrate this point:—

Labor—711	Material—712
711.01 Digging (general)	712.01 Lumber
711.02 Digging sub-basement	712.02 Underpinning adjacent buildings
711.03 Sheeting and bracing banks	712.03 Rings (steel)
711.04 Shoring adjacent buildings	712.04 Cement

For convenience we have listed the charges of labor and material in the order they usually appear in building construction costs:—

Labor	Material
.01 Digging (general)	.01 Lumber
.02 Digging sub-basement	.02 Underpinning adjacent buildings
.03 Sheeting and bracing banks	.03 Rings (steel)
.04 Shoring adjacent buildings	.04 Cement
.05 Underpinning adjacent buildings	.05 Sand
.06 Pumping	.06 Stone
.07 Back-filling and grading	.07 Brick
.08 Cutting old footings	.08 Wall tie and inserts
.09	.09 Steel (structural)
.10 Placing lagging and rings	.10 Steel (reinforcing)
.11 Ventilating	.11 Nails and wire
.12 Mixing and placing concrete	.12 Clamps, purchased or rented
.13 Building forms general	.13 Tile
.14 Building forms exterior columns	.14 Protection (lumber, etc.)
.15 Building forms interior columns	.15 Terra cotta
.16 Building forms spandrels	.16 Granite
.23 Lay brick	.25 Frames and sash
.26 Bend steel	.30 Interior trim
.35 Set cut stone	.35 Coping
.44 Fit and hang doors	
.56 Unload and handle material, etc.	
.60 Clean up rubbish	

Add as many new accounts as are needed.

Should charges be made in connection with concrete and fireproofing under subdivision 750, they would follow the same order as in excavation:—

751.12 (Labor) mixing and placing concrete
752.04 (Material) cement
753 Liability insurance

Or, carpentry, sub-division 770:—

771.44 (Labor) fit and hang doors
772.25 (Material) frames and sash
773 Liability insurance

Classification of Plant Expense

Sub-division 800 covers plant expense and conforms with the sub-classification of the 700 accounts as much as practicable. The following are the headings under 800:—

801 Excavation	806 Masonry
802 Caissons	807
803 Footings	808
804 Sawmill	809 General (items charged to general equipment)
805 Concrete and fireproofing	

A further typical subdivision of the accounts under this heading is:—

801 Excavation	801.3 Equipment on charge and credit basis
801.1 Transportation (of equipment plant)	801.31 Labor
801.2 Erection of equipment	801.32 Material
801.21 Labor	801.4 Rental of equipment
801.22 Material	801.5 Fuel, lubricants and power
	801.6 Repairs

Should charges to plant in connection with concrete and fireproofing be made, they would be charged as 805 with divisions shown above.

Field Overhead

811—Salaries, general labor and expense	*812—Engineering expenses*
811.1 Superintendent and engineers	812.1 Plans, detail and engineering supplies
.2 Office employees	.2 Photographs
.3 Material men and timekeepers	.3 Engineering service
.4 Laying out building	.4 Architects' fees
.5 Watchman	
.6 Waterboys	
.7 Toolmen	
.8 Liability insurance, superintendent and watchman	
.9 Travelling expenses, superintendent, engineers, and office men	

813—Office expense	
813.1 Rent, light and heat	.6 Rent on adding machine and typewriters
.2 Stationery and printing	.7 Furniture
.3 Telephone	.8
.4 Telegraph	.9 Miscellaneous office expense, towels, etc.
.5 Postage and express	

814—Other fixed expenses
814.1 Bonds (maintenance and construction)
.2 Permits and licenses, boiler inspection
.3 Fire insurance
.4 Legal services
.5 Burglar insurance
.6 Association dues
.7 Advertisements
.8 Floor tests
.9 Ring tests

Statement of Construction Cost

At stated periods we take from he cost records a summary and de- ail statement of construction costs n the following form:—

Acct. No.	Name of Acct.	Item	Amount	Cost per Unit	Est. Cost	Diff.

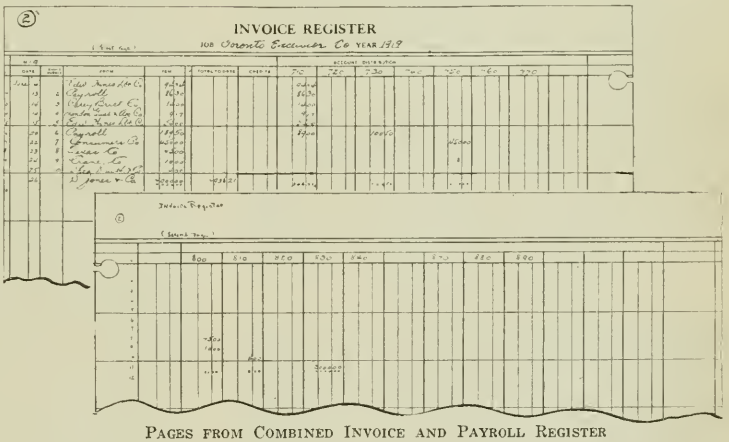
The last column is in black or ed; naturally the red items will ave careful scrutiny to ascertain hy costs are running above esti- ate. This statement is primarily or our own use, but the owner may ave a copy if he wishes.

Owner Knows Total Expenditure

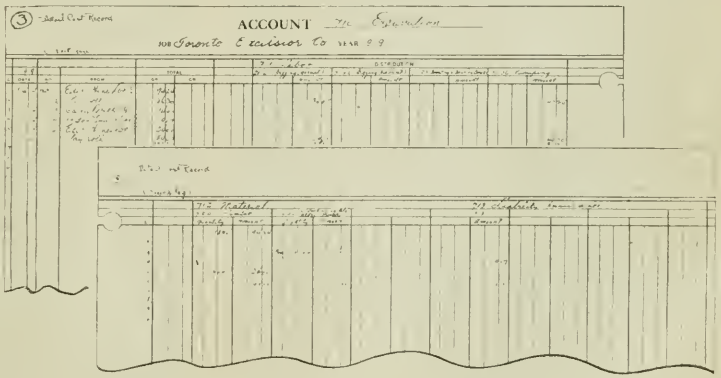
Under the cost-plus-fixed-fee ontract, the owner generally rnishes the funds to finance the ontract. We maintain an entirely parate bank account for each cost- us contract, representing the own- 's funds, and where agreeable to the owner, we arrange for the owner's representative to countersign all checks drawn by us on this account. At the start of the work we furnish to the owner an estimate of the anticipated amount of labor and material bills covering an initial period of two weeks or more, and the owner then advances the funds to cover these requirements. When the owner's receipted copies of vouchers covering this period are returned from the vendors, a statement is given to the owner showing amounts actually paid for payrolls, materials and sub-contract work, with receipted vouchers attached. That total is then credited to us by the owner on account of contract.

The advantages of having all accounts handled at the job are apparent. The distribution, if not clear from the purchase order, can be referred to the superintendent and the fact that the books of accounts are at all times open for the owner's inspection, is an assurance to him of honest treatment. The fact that he approves purchases of materials before made and again has the opportunity of questioning invoices prior to payment, leaves the control with him and prevents the accumulation of minor, disputed items, which if left for settlement until the completion of the contract, might not be readily explained.

But a system of accounts, no matter how perfect, cannot influence the cost of work except as it points out from time to time divergence from the preliminary estimate, the assumption being made that such differences are promptly taken in hand, the reasons investigated and the remedy applied. The success of work under the cost-plus contract



Pages from Combined Invoice and Payroll Register



Pages from Detail Cost Record

is still dependent upon the integrity of the contractor and his ability to perform.

We have used this system of accounting with entire satisfaction to the firms mentioned above and many others, and we are now engaged in work at Halifax, N.S., on this same basis. This is adequate proof that the cost-plus contract is workable and that the owners not only feel safe but prefer this method because under it 90% of the savings under the preliminary estimate accrue to the owner, because the 10% retained by the contractor is a reasonable incentive to make every possible saving, and because additional costs incurred through no fault or omission of the contractor are rightly chargeable against the owner and should not reduce or wipe out the contractor's profit.

There is incentive for the contractor to make all possible savings under both old and new contract, and some of the savings must go to the contractor to give him that incentive; 10% is adequate and the 90% going to the owner builds a good-will account which practically assures repeat orders as new work becomes necessary. The building of a relationship which will ensure repeat orders is just as important in contracting as in merchandising.

The Engineer's Library

GENERAL LECTURES ON ELECTRICAL ENGINEERING

REVIEWED BY A. H. HULL
Assistant Electrical Engineer, Hydro-Electric Power Commission of Ontario

By Dr. Charles Proteus Steinmetz. Published by the McGraw-Hill Book Co., Inc., New York City. Fifth edition; 248 pages; 6 by 9 ins.; illustrated. Price, $2.50.

This book is a collection of eighteen lectures dealing with direct and alternating current distribution, effect of load factor on the cost of power, generation and generator wave form, hunting of synchronous machines, transmission, oscillations and surges, and lightning protection.

Three lectures are devoted to electric railways and railway motors. Electrochemistry, arc lighting and incandescent lamps are treated in separate lectures.

The last lecture deals with the use of power limiting reactors in large systems. Two appendices are included, the first being part of an address before the Franklin Institute in 1914, on the effect of electrical engineering on modern civilization. The second consists only of a table of resistances and reactances for overhead wires and seems to be entirely out of place in the book.

The lectures are free of mathematics, the subjects being treated in a general descriptive manner. While the book does not attempt to cover the entire field of electrical engineering, a careful reading of it will give the advanced engineering student, or the young engineer, a comprehensive general outline of that part of electrical engineering that has to deal with the problems of generation, transmission, distribution and utilization of electric energy.

Save for the next "Victory Loan." Your money is needed to ensure national prosperity.

RELATION BETWEEN WATER SUPPLY AND GOITER

AN apparent connection between goiter and water supply in various parts of the world is traced by Mayo Tolman, chief engineer of the West Virginia State Department of Health, Charleston, W. Va., writing in the "American Journal of Public Health."

Goiter, which manifests itself as an enlargement of the thyroid gland, shows high endemicity in Switzerland, parts of France, and in regions in every continent. In North America the main endemic centres are in parts of New Hampshire, New York, the Blue Ridge Mountains of Virginia, nearly all of West Virginia, the region about the Great Lakes, and Edmonton, Alt. Recent studies by Mr. Tolman indicate that there are 12,000 cases in West Virginia, while in Broxton County a house-to-house survey showed 1,148 cases, or 1 to every 20 inhabitants.

The cause of the disease is most generally attributed to the character of the drinking water. Efforts to connect the disease with various inorganic impurities in the waters of the region have not been successful, Mr. Tolman states. The relation seems to be with the geological ages of the rocks of the regions.

"Apparently," Mr. Tolman says, "volvanic formations, the crystalline rocks of the Archaic period and all deposits laid down in fresh water, are free from the goiter-producing characteristic." In the United States the greatest endemicity is found in paleozoic areas. In West Virginia water from the coal measures seems to cause the disease, while in the same valleys people taking water from higher in the mountains, above the coal measures, have less goiter as the elevation increases.

"This association of goiter with certain geologic time," says Mr. Tolman, "would indicate that the disease is not caused by a living organism, but is due to some substance derived from marine animals in past time. What this substance is, is not known, but experiments indicate that it is not retained by a Berkefeld, and that its goiter-producing property is destroyed by heating to 70 deg. C. It is, of course, possible that goiter is a deficiency disease, that the marine animals of geologic time used up a certain substance in the water that is essential to animal economy. This theory is severely shaken, however, by the fact that heat evidently destroys the goiter-producing element, but nevertheless it should not be entirely abandoned at the present stage of our knowledge.

"Goiter presents phases that should be of interest to health officers in those areas in which it occurs, and it is to be hoped that the disease will be given more study in order that its cause may be definitely determined, for without accurate knowledge of the cause of a disease, any measures to combat it may be hit-or-miss. There can be little doubt that the efficiency of a community is lowered by endemic goiter; consequently the spread of the disease should be prevented."

The first general meeting of the Canadian Association of British Manufacturers and their representatives was held September 8th in Toronto. John Wilson presided, and pointed out that the 55 members of the association represent over 300 British manufacturers. The association hopes to have a representative in London, and that in time it will become as large as the C.M.A. Trade sections of the association were formed, and the chairmen will form a publicity committee. The appointment of tariff and transportation committees are to be looked after by the executive committee. F. W. Field, trade commissioner, reported that the British trade commissioners in Canada have been granted authority by the department of trade and commerce to appoint an expert to deal with all matters of dispute in regard to quality of goods. Capt. John Harris stated that there are in Toronto 250 representatives of British firms.

USEFULNESS OF VEGETATION IN MARITIME ENGINEERING*

By E. T. P. Shewen, M.E.I.C.
Consulting Engineer, Public Works Department of Canada, St. John, N.B.

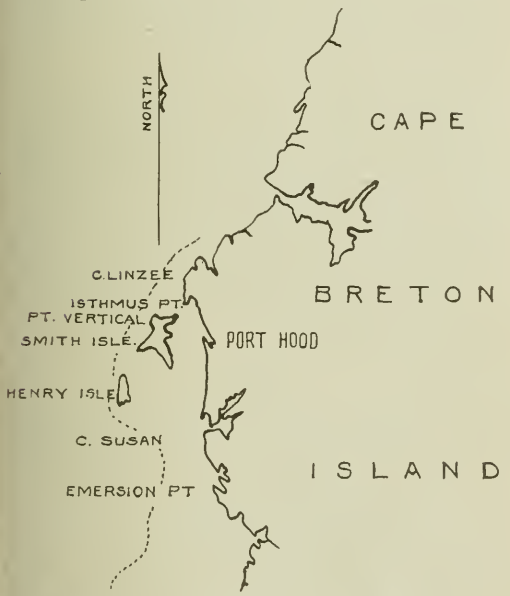
"BRITISH engineers have perhaps been somewhat apt to disregard those transformations which are capable of being brought about by vegetation."

This remark is found in the preface to a book recently published, entitled "Tidal Lands: A Study of Shore Problems" (1918), by A. E. Carey, of London, Eng., and F. W. Oliver, professor of botany in University College, London, Eng.

A convincing illustration of the value of vegetation as a protection against inroads of the sea, was given about ninety years ago in the maritime provinces, by the destruction of a fine harbor at Port Hood, on the west coast of Cape Breton.

Port Hood Harbor

This shelter, 2 miles long and 1¼ miles broad, was formed by the junction with the mainland of Smith's (or Port Hood) Island, which constituted the western barrier, presenting on the east a concave side. From Emersion Point, 4 miles below the harbor, to Dean Shoals, abreast the middle of the island, the coast lies north and south but then trends N.N.W. for 1½ miles to Isthmus Point, there turning due north to Cape Linzee, ½ mile away. At Cape Linzee, the shore swings N.N.E., and continues in that direction almost in a straight line for some miles.



Map Showing Cape Breton Coast Line in the Vicinity of Port Hood

The connection was made by a sand beach, or bar, starting from the shore at Isthmus Point and running nearly ¾ mile S.S.W. to the head of the island.

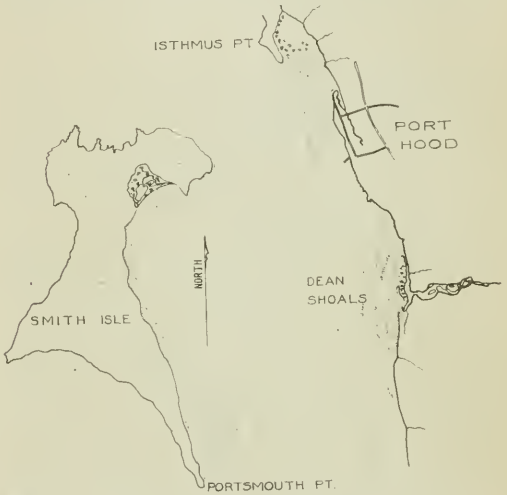
In respect to the littoral drift which made the isthmus, it is worth noting that the line of it, if produced N.N.E., practically coincides with the coast-line for 10 miles from Cape Linzee.

*Paper read at the fifth professional meeting of the Engineering Institute of Canada, September 10th to 12th, 1919, St. John, N.B.

A deep and capacious haven was thus made between the island and the main, large enough to hold a fleet, and affording at best more than seven fathoms of water. Concerning the holding-ground, there is no present information, for the bottom was covered with sand and the depth shoaled when the isthmus was washed away. The harbor was open to the south alone, and in that quarter the fetch is only 21 miles to the Nova Scotian coast. The conditions of a good, natural harbor were therefore fairly fulfilled.

The isthmus was covered with grass, so long, according to statements made a quarter of a century ago by some of the older people of the place, that the children who had to cross to reach the school, used to play hide-and-seek in it on the way.

Unfortunately, cattle were turned out there to graze, and disaster followed. One of the eye-witnesses of the consequent destruction of the sand beach (and from his apparent age, one of the school-children mentioned), said that he considered the greater damage was done by the hoofs of the cattle in uprooting, and that the actual cropping was a minor evil. In any case, the grass was killed by the cattle, and the sand above high-water, no longer held in place by the roots or protected by the stalks, was blown away by the wind until the crest of the beach, formerly several feet above high water, was soon lowered to that level. A breach, small at first, was shortly after made by the sea.



Map Showing Dean Shoals and the Sand Bars That Have Formed in Port Hood Harbor

Isthmus Swept Away

Seeing an opportunity for making a navigable outlet which would save a long sail round the tail of the island in reaching the northern waters, the fishermen enlarged the breach to a size sufficient for a boat-channel. The sea did the rest. Not long afterwards the whole isthmus was swept away, the harbor utterly destroyed, and only an open roadstead left in place of it.

The grass which had preserved the harbor for an unknown period by holding the sand composing the northern bulwark, was evidently a valuable and hardy species, consequently about twenty years ago search was made to find if any of it had survived in some sheltered nook lower down the shore, where the sand and roots must have been carried (part of the sand lodged on Dean Shoals) since the littoral drift follows that direction.

In a cove filled with sand, some distance to the south, grass of the same kind was discovered in quantity, and on being sent to the Experimental Farm for examination, it was

pronounced to be *calamagrostis arenaria*. It was then decided to plant some of it at Negropoint in order to stop the dry sand drift at that time being blown over the top of the work into the harbor of St. John, and also in order to assist the increase of the natural face on the weather side of the breakwater pending its extension to Partridge Island.

Transportation from Cape Breton did not become necessary, for the resemblance of the grass at the head of Courtenay Bay to the Port Hood specimens was observed, and they were found to be identical. Roots were accordingly transplanted from Courtenay Bay to Negropoint, and the desired effect was produced.

On the sandy eastern coast of New Brunswick, and on the shores of Nova Scotia and Prince Edward Island, opportunities occur for the use of this grass, and wherever accumulation of sand is observed to be taking place alongside a new work, it might be prudent, for the purpose of retarding the formation of dunes, to plant it as soon as the littoral drift collected rises a few feet above tide-level.

Advantageous Uses for Grass

If erection of the long piers at Cape Traverse in Prince Edward Island, and at Richibucto in this province, did not actually originate formation of the dunes at those places, it at least contributed to increase their size, because both works caused advances of the foreshore. According to the authors of "Tidal Lands," dunes can be formed as soon as the sand flats of the foreshore rise high enough to allow the surface to become sufficiently dried between tides for the wind to blow the thin dry layer landward.

At Cape Tormentine, on this side of Northumberland Strait, there are wide sand flats dry for a considerable period of each tide, but no dunes, because the prevailing strong wind blowing up the Bay of Fundy and across the low isthmus of Chignecto is off-shore from the New Brunswick coast.

Dunes, are, however, found at Cape Traverse on the opposite side of the strait and nine miles distant, where the same wind is on-shore, and where the sand flats as already mentioned were enlarged by the construction of a long railway pier of solid cribwork So rapid was the spread of the strand there, that the workmen said the sand came out to the end as soon as the pier was built. Quantities travelled round the end and, lodging under the lee, went on either to make or augment the dunes on the farther side of the cove.

At Mabou, ten miles north of Port Hood and on the same coast, dunes have overwhelmed the land, killing the trees and all other vegetation.

The dunes at Richibucto are formed on waste or inferior land, and in consequence have so far caused little damage.

In such places, *calamagrostis arenaria* might be cultivated with advantage. No doubt other varieties of shore plants, useful in greater or less degree for holding or protecting by root or top the dry sand, might be discovered on the shores of these provinces.

The lessons taught by the catastrophe of Port Hood are evidently:—

Lessons Taught by Catastrophe

(1)—To preserve the useful shore grasses, in particular by the exclusion of livestock from beaches.

(2)—To plant *calamagrostis arenaria* betimes, when sand-spits or beaches are being denuded by wind action.

Wherever a breach in the numerous dry sand bars found in this region is being made, after restoring the beach to proper height for survival of the roots, the engineer would act wisely in planting bent-grass.

Movement of the dunes on the European and also on the Australian continents, is being prevented by systematically setting, according to prescribed rules, roots of this grass as a first step, followed by cultivation of other suitable plants as the dunes become fixed.

Botanical investigation of the sandy coasts of Canada, with the view of ascertaining the different kinds of indigenous plants capable of holding sand, which flourish best at varied elevation above high-water (say from 10 ft. to 60 ft.), would furnish information useful to the maritime engineer in hindering the development of sand dunes or in arresting their movement when formed.

PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSING OF TURBINE GATES*

By Eugene Halmos
Designing Engineer, Barclay Parsons & Klapp, New York

EVER since the publication of the paper† entitled "Penstock and Surge-Tank Problems" by Minton M. Warren, the writer has hoped that some one would point out the injustice done to one of the greatest hydraulic engineers of the present age by the form of, and the comments appended to, Mr. Warren's presentation of what he termed "Alliévi's formula."

Unfortunately, Mr. Warren has not been corrected. This formula was accepted by American engineers as representing Alliévi's solution of the problem of water-hammer in pipe lines, and, consequently, it has been severely criticized and misinterpreted.

The value of Mr. Gibson's excellent paper is also seriously impaired by the references, both in the text and in the diagrams, to "Alliévi's formula" as taken from Mr. Warren's paper, and the writer would suggest that, after perusal of the following, Mr. Gibson omit all reference to Alliévi, except to state that his solution agrees, in every particular, with that of Alliévi.

The writer proposes to submit a brief summary of Mr. Alliévi's formulas, which, in his judgment, represent a complete solution of water-hammer problems as regards determination of the pressure at the gate or at any other section of the conduit, at any instant, and under any conditions of closure and physical characteristics of the plant. It is more general than Mr. Gibson's solution, inasmuch as it also includes the determination of the pressure variations after the stopping of the gate movement, and as it gives a method of estimating the interval in which the pressure maximum will occur.

As the present paper and the previous ones deal almost exclusively with the case of water-hammer during the closure of gates, and with the variation of the pressure at or near the gates, the writer will only quote Alliévi with regard to formulas applicable to such cases. The writer, however, intends to translate Alliévi's book into English, which, it is hoped, will be of great help to designers of hydraulic plants and apparatus.

In the following, the formulas representing the relation of time and pressure are given for three phases, namely,

the first phase, for which $t \leqq 2L/a$;
the second phase, for values of t beginning with $t=2L/a$ and ending at T;
and the third phase, $t>T$.

Notation

a = velocity of propagation of pressure along pipe;
c_0 = uniform velocity of water in pipe before beginning of gate closure;
C = variable velocity of water in pipe at any instant during gate closure;
u_0 = uniform velocity of water through gate orifice before beginning of closure;
u = variable velocity of water through gate orifice during gate closure;
t = time, in seconds, recorded from beginning of gate movement;
T = duration of gate movement, assumed to be continuous;
L = length of pipe conduit;
y_0 = pressure head on pipe line at gate before closing begins;
y = variable head at gate due to closure.

General Formulas

(1) *Variation of Pressure Head During and After the Closing Motion of the Gates.*—

*Discussion (presented to the American Society of Civil Engineers) of Norman R. Gibson's paper (see September 4th and 11th issues of *The Canadian Engineer*).

†"Transactions," Am. Soc. C.E., Vol. LXXIX, p. 238.

First phase, $t \leqq 2L/a$.

For this interval, the pressure head, y, at any instant can be computed from the equation.

$$y^2 - 2y[H + a^2\psi^2(t)/g] + H^2 = 0 \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

in which $H = y_0 + ac_0/g$

and $\psi(t)$ is the ratio of the instantaneous area of discharge to the area of the gate opening at the time, $t = 0$, the value of $\psi(t)$ being taken at the instant for which the pressure head, y, is calculated.

It will be noted that if the gate is closed in a time, $T \leqq 2L/a$, $\psi(T) = 0$, and the equation reduces to

$$y^2 - 2Hy + H^2 = 0$$

$$y = H = y_0 + ac_0 g \quad \ldots\ldots\ldots\ldots (2)$$

which shows that in such a case the maximum pressure head is independent of the actual length of the time of closure.

Of the two roots of Equation (1) one is greater, the other is smaller, than H. This latter is the true value of the pressure head at any instant.

Second phase, $2L/a \leqq t \leqq T$.

During this period of the gate movement, the following equation applies for the determination of the pressure head at any instant:

$$y^2 - 2y[H - 2f + a^2\psi^2(t)/g] + (H - 2f)^2 = 0 \quad \ldots\ldots\ldots (3)$$

Of the two roots of Equation (3), that giving the smaller value should be used.

It will be noted that this equation differs from Equation (1) only in so far that, instead of H in the latter, $(H - 2f)$ appears in Equation (3).

The values of the function, f, should be determined in the following manner:—

For the interval, $0 < t < 2L/a$, $y - y_0 = F(t)$, y being calculated from Equation (1).

The velocity, C, in the conduit (at the gate) can be computed from the equation

$$y + (a/g)C = H$$

for this interval.

For the interval, $2L/a < t \leqq 4L/a$; $f = F(t - 2L/a)$; in other words, the values of $F(t)$ found in the first interval should be substituted for f in Equation (3) to obtain the value of y for every subdivision of the second interval. Then the corresponding values of the velocity, C, may be found by $y + (a/g)C = H - 2f$, and the value of $F(t)$ for the second interval by $F(t) = (a/g)(c_0 - C) - f$.

For the third interval, $4L/a < t \leqq 6L/a$, the values of $F(t)$ so found for the subdivisions of the second interval should be substituted for f in Equation (3) to get y, and so on, for all subsequent intervals until the gate has stopped moving or has become entirely closed.

Third phase, $t > T$.

If the movement of the gate is stopped at an instant such that $t_1 < 2L/a$, the pressure head, y, remains constant until $t = 2L/a$. From this instant on, or from the time of the stoppage, in the case, $t_1 > 2L/a$, there is developed a hydrodynamic phenomenon in the form of an asymptotical approach of the pressure head, y, to the new constant head, y_0, of uniform flow. There are three different cases.

First.—If $a\psi(t_1) > u_0 + u_1/2$, in which case y approaches y_0 without oscillations.

Second.—If $a\psi(t_1) < u_0 + u_1/2$, in which case y approaches y_0 through oscillations of diminishing amplitude.

Third.—If the gate is entirely closed, $\psi(t_1) = 0$, the pressure head (disregarding the dampening effect of hydrodynamic friction) oscillates indefinitely, with a constant amplitude, between the value of y, which occurs at the instant of closing, and $2y_0 - y_3$, the amplitude being $y_3 - y_0$.

(2) *Estimating the Phase in Which the Maximum Pressure will Occur.*—Assuming a linear closure of the gates:

(a) If $ac_0 < 2gy_0$, then the pressure head at the end of the first phase ($t = 2L/a$) will always be greater than the average maximum pressure [found by Equation (4)] occurring during the second phase.

(b) If $2gy_0 < ac_0 < 3gy_0$, the maximum pressure head occurs either at the end of the first phase, or during the second phase, according to whether the closing time, T, is smaller or greater than $[ac_0 - gy_0)/(ac_0 - 2gy_0)](L/a)$.

(c) If $ac_0 > 3gy$, then the maximum pressure will always occur during the second phase and will be greater than that at the end of the first phase.

Equations (1), (2), and (3) are the general formulas derived by Alliévi, by the help of which complete pressure-time curves can be worked out for any assumed conditions of T, L, a, c_0, and y_0. The writer is very much pleased to state, that, by the use of these equations, he was able to check accurately all the curves presented by Mr. Gibson. He wishes to compliment the author in having found, quite independently, and by a simpler mathematical method than Alliévi's functional derivation, the correct formulas for the representation of pressure-time curves and related phenomena.

Special Formulas

It has been found by experiment, and by working out pressure-time curves for a great number of cases actually met in practice, that, on the assumption of linear gate closure:

(d) The pressure behind the gate remains practically constant for $2L/a < t \leqq T$ (y is not a function of time or $dy/dt = 0$ between these limits) and, therefore, for this period, the pressure is independent of the elastic qualities of the water and the conduit, in other words, independent of (a);

(e) The pressure is distributed in a linear way along the pipe;

(f) The velocity of the water, C, is the same at any instant at any section of the conduit $(dc/dx = 0)$.

Taking into consideration the observations noted under (d), (e), and (f), a good average value of y maximum during the second phase can be obtained by solving the equation

$$Z^2 - Z(n^2 + 2) + 1 = 0 \quad \ldots\ldots\ldots\ldots (4)$$

where $Z = y_{max}/y_0$ and $n = c_0 L/gTy_0$.

This equation is identical with Equation (C) in Mr. Warren's paper. In order that it should be valid, it is necessary:—

(1) That T be greater than $2L/a$;

(2) That the gate movement (the rate of reduction of the area of the outlet) be a linear function of the time;

(3) That, in case of partial closure, that value of T should be used which would be obtained if the gate should be completely closed at the same rate of speed;

(4) That the physical data, as L, a, y_0, and c_0, shall conform to those ordinarily met in practice.

In order that Equation (4) should produce the maximum pressure head obtaining during the whole movement of the gate, it is necessary that ac_0 shall take the values defined under (b) and (c).

It is evident that Mr. Warren committed a serious error by omitting the publication of Alliévi's general Equations (1), (2), and (3), and by omitting the proper definition of Equation (4) and the limitations of its applicability as defined by Alliévi.

The only ambiguity which may occur in using this formula is the lack of a better definition of Condition (4). This is extremely difficult, on account of the great number of variables entering into the problem. The writer, however, proposes without being able to give strict analytical proof at the present time, that Equation (4) should be used only, if

(α) $Lc_0/gTy_0 < \frac{1}{2}[ac_0/y_0g + y_0/(y_0 + ac_0/g) - 1]^{\frac{1}{2}}$; and,

(β) $ac_0 > 2gy_0$.

As L, c_0, a, and y_0 are dependent on rather unalterable physical conditions, if Condition (β) is satisfied, Condition (α) can be fulfilled by determining T according to the proposed formula.

If, besides Conditions (α) and (β), Conditions (b), (c), (1), and (2) are also fulfilled, Equation (4) will give the absolute maximum head at the gate during the movement of the apparatus.

It will be found that,

for $c_0 \leqq 10$ ft. per sec.

y_0 = between 100 ft. and 500 ft.

$T \leqq 6$ intervals,

all the foregoing conditions are fulfilled, which means that, in most practical cases, Equation (4) actually furnishes the maximum pressure head at the gate.

If the elasticity of the water and the conduit is neglected for the whole time of the movement of the gate, then, for the conditions for which Equation (4) is applicable, the pressure-time curve can be platted from the equation:

$$\log. \sqrt{[(u_0^2+u_R^2)^{1/2}+u-u_R][(u_0^2+u_R^2)^{1/2}-u_0+u_R] \div [(u_0^2+u_R^2)^{1/2}-u+u_R][(u_0^2+u_R^2)^{1/2}+u_0-u_R]} = [(u_0^2+u_R^2)^{1/2}-u_R] \log. [T(T-t)] \quad \ldots\ldots\ldots (5)$$

in which $u_R = K(t.T)$, where K is the ratio of the area of the gate opening at $t = 0$ to the area of the pipe, and $u_0 = (2gy_0)^{1/2}$, $u = (2gy)^{1/2}$.

This curve will have a maximum at $t = T$ if Conditions (b) and (c) are fulfilled, and will have a practically horizontal position in the second phase if Condition (a) is observed. It will differ very little from the true curve of pressure variations, and is applicable to practically the whole range of actual water-power problems.

It will be noted that Equations (4) and (5) are identical with Equations (6) and (7) given by R. D. Johnson in his discussion* of Mr. Warren's paper. Great credit is due to Mr. Johnson for having grasped correctly the essential features of this difficult subject, and for his wonderful mathematical skill in solving by independent methods the intricate problem of water-hammer.

In conclusion, the writer wishes to observe, that it would be desirable to encourage the use of Alliévi's, Gibson's, and Johnson's formulas for water-hammer, and to reject and discourage the use of other formulas, some of which, such as Mr. Warren's, are never true, not even accidentally.

*"Transactions," Am. Soc. C.E., Vol. LXXIX, p. 280.

JAPANESE DECISION ON TRADE MARKS

IN a suit instituted by a Philadelphia manufacturing company for the protection of its trade-mark rights, the Supreme Court of Japan has handed down a decision which upholds every essential of trade-mark rights guaranteed under Japan's treaty agreements with the United States and other countries. It places the spirit of the law of Japan on a plane equal to that occupied by western peoples, and it affects, directly and most favorably, manufacturing interests involving annual production on this continent amounting to billions of dollars.

The trade-mark concerned in the litigation is that of the Miller Lock Co., of Philadelphia. This trade-mark (a scroll containing the word "Miller"), was registered in the U. S. Patent Office, October 8th, 1906, and in 36 other countries, date of registration in Japan being March 26th, 1907.

The discovery was made in 1916 that the Crown Lock Co., of Tokyo, Japan, was manufacturing imitations of the Miller padlocks and stamping them with a facsimile scroll containing, in one instance, the word "Crown," and, in another, the word "Million."

Legal proceedings against the infringing company were begun in the Japanese Patent Office at Tokyo, and the fight undertaken with a resolve to end definitely, if possible, all invasions against trade-mark rights, was based upon the weakest aspect of the owners' contention. Instead of alleging infringement by the scroll containing the word "Million," they claimed redress against the infringement committed by means of the scroll containing the word "Crown."

The Miller Lock Co.'s averment, therefore, claimed practically on the scroll alone and risked much by its voluntary choice. But, on the other hand, it put squarely up to the administration of Japanese law and treaty rights the essential principles involved in trade-mark suits and called for a definition of unfair trade competition which must be on a par with the spirit and the administration of the law in the most advanced and just of western countries. In a word, the fight was not one wholly of self-interest; it was undertaken for the benefit of the world's trade and for Japan's welfare no less than that of other countries.

The most distinguished legal talent of Japan was engaged in the struggle, and court and patent office records were searched exhaustively for precedents.

The decision reached is made just as Japanese padlocks, bearing the alleged scroll, are invading Canada.

NEW ENGLAND WATER WORKS ASSOCIATION

FOLLOWING is the program of the thirty-eighth annual convention of the New England Water Works Association, to be held September 30th to October 3rd in Albany, N.Y.:—

"The Operation of and Purification Effected by the New Drifting Sand Filter System at Toronto," by Norman J. Howard, bacteriologist-in-charge, Filtration Plant Laboratory, Toronto.

"Swimming Pool Management," by William P. Mason, professor of chemistry, Rensselaer Polytechnic Institute, Troy, N.Y.

"The Supervision of Public Water Supplies by the New York State Department of Health," by Theodore Horton, chief engineer, New York State Department of Health, Albany, N.Y.

"Schoharie Development of the New York Water Supply," by J. Waldo Smith, chief engineer, Board of Water Supply, New York.

"Water Supplies for the American Expeditionary Forces," by Francis F. Longley, consulting engineer, New York.

"Watershed Leakage," by Robert E. Horton, consulting engineer, Voorheesville, N.Y.

"Hydraulic Fill Dams of the Miami Conservancy District," by H. S. R. McCurdy, division engineer, Miami Conservancy District, Englewood, O.

"The 10-Million Gallon Covered Reservoir of the Dayton Water Works," by Leonard Metcalf and William T. Barnes, consulting engineers, Boston.

"Dangerous Reduction to Insulation Resistance in High Presure Fire Service Motors Due to Moisture," by William W. Brush, deputy chief engineer, Department of Water Supply, Gas and Electricity, New York.

"Detection of Losses from Underground Piping Systems," by Paul Lanham, engineer in charge of waste detection, Washington, D.C.

"Experience in Metering Fire Services," by Frederic E. Beck, chief engineer, Consolidated Water Co., Utica, N.Y.

"Painting Standpipes," by Charles W. Sherman, consulting engineer, Boston.

"Pumping Engines for Small Water Works Plants," by Creed W. Fulton, of the Goulds Mfg. Co., Boston.

"Tests of the Uniflow Pumping Engine," by D. A. Decrow, of the Worthington Pump and Machinery Corporation, New York.

"Guarantees or Assessments for the Extension of Main Pipes," by Bertram Brewer, assistant engineer, State Department of Health, Boston.

A. E. Doucet, director of public works of the city of Montreal, recently recommended to the city council that the claims of Pion & Grothe and of T. Sullivan, formerly contractors for the La Salle Bridge, be settled by returning Mr. Sullivan's deposit of $21,000 and paying him about $6,300 additional, and by returning Pion & Grothe's deposit of $24,000 and paying them about $16,000 additional. Mr. Sullivan's claim was for $56,000 and Pion & Grothe's amounted to over $95,000. This suggested settlement has been rejected by the city councillors, who decided that it did not comply with the Act passed by the Quebec Legislature during the last session, which stipulates that the contractors be paid the value of the work they performed as at the time of performance, together with compensation for all outlays in connection with the contract, these amounts to be calculated without profit to the contractors. The Act stipulated that if a settlement were not made within six months, the city and the contractors were to refer the claims to arbitrators.

THE CASE AGAINST PAYMENT TO CONTRACTORS FOR ESTIMATING

By William Graves Smith
President, Quantity Survey Co., New York

[*General contractors have evidenced considerable interest in the "Nelson Form," the "Kelley System" and other proposed methods of paying contractors for the preparation of estimates. The "Committee on Methods" of the Associated General Contractors of America has requested statements, for purposes of investigation, from the promotors of the various proposed systems of payment, and from W. G. Smith, who is representing the interests of the quantity surveyors. The following is the statement that was recently submitted to the committee by Mr. Smith.*—Editor.]

CONTRACTORS are becoming restless. They are seeking relief from conditions that are recognized as unfavorable, and the very fact of the creation of a national organization shows that they are beginning to reason about the causes of discontent and to study how to improve matters.

One measure of relief proposed is the demand for payment for estimating. Another receiving considerable attention is the introduction of the quantity surveyor to supply uniform quantities as the basis of all bids. Before discussing them it will be well to consider some of the fundamental economic features of construction.

Fundamentals in Construction

It is the building owner who eventually pays for all expense. The overhead expense of architects and contractors, which covers miscellaneous expense of all sorts on projects that do not eventuate in contracts for them, is collected on the jobs for which they do receive contracts. Building owners, therefore, pay indirectly for all estimating and quantity expense.

Again, there should be a sharp distinction drawn between estimating expense and quantity expense. As used in this report, estimating expense will mean the expense of determining labor and material prices and everything else that enters into pricing up quantities of work to be done, except the expense for the preparation of quantities. This is considered as distinct from estimating expense.

Estimating is a part of a contractor's work that by no method can be satisfactorily delegated to any outsider. No method of payment for it can in any way relieve him of the necessity of doing it for himself and for assuming full responsibility for the prices he offers for doing the various kinds of work required under any contract. There is undoubtedly considerable confusion among contractors in discussing payment for estimating due to its close relation to quantity preparation, and by many it is considered as covering both matters. There can be no escape from estimating expense; but there are ways which will be explained to minimize quantity expense in a very desirable and satisfactory manner.

There is a sad misconception or disregard of "overhead" on the part of many contractors. Some say, for example, that estimating expense comes out of "profit." If a contractor does not know what percentage of his receipts goes to pay for rent, insurance, interest, salaries for estimators, etc., or doesn't care to account for these items in his estimates as "overhead," it is a matter for his choice and decision. But if he does not account for his "overhead" as a separate item in his bids, he should not complain if his so-called "profit" is reduced by payment of such items.

Competition vs. Speculation

There must be competition. Anything permitting or leading to the development of a building trust will be disastrous to the interests of the majority. On cost-plus work, even, there should be competition for a percentage contract among acceptable builders, to demonstrate their ability to give service. Service can only be measured ultimately in terms of cost. On the other hand, competition can only exist when uniform requirements are made the basis of competition. Anything else is speculation. Constructive ability and management should be the winning and determining factor. Until they are, and until a generally accepted minimum percentage of profit is demanded by all, the contractor's existence will continue to be a stormy one.

Anything that decreases a contractor's "overhead" or allows him to figure "costs" more accurately, or gives him better opportunity to demonstrate his superior constructive and executive ability, without increasing cost to the building owner, is a good thing for both parties.

Payment for Estimating

Direct payment for estimating would not reduce a contractor's expense for same. His overhead would not be reduced, for a contractor would not be furnished anything that would reduce his labor or lessen his responsibility. It would simply change the method of reimbursement and shift the burden of expense. Contractors that properly treat "overhead" as something separate from "profit" know that they collect in "overhead" all of their estimating expense from the jobs they win. The building owner that gives them a contract pays for the estimating on his own job and on an average for about fifteen or twenty others that his contractor has bid on and lost, or which did not go ahead.

This may seem a hardship to building owners, but looked at from this standpoint, it is not a hardship to contractors. There are, however, many reasons why estimating expense cannot be satisfactorily paid for job by job with any hope of the building owner reaping any benefit financially or otherwise.

In other business, estimating expense or pricing is recovered as an overhead item. Take for example the simple transaction of buying the winter's supply of coal. A coal dealer doesn't charge a separate fee for giving a price for coal delivered at your residence. He has computed the cost to unload and store the coal. He knows what it costs on an average to haul coal within the radius of his district. You don't expect him to figure out a price for you at so much per ton-mile for delivery at your door and to pay him for making the estimate. No; when you ask a price for a definite amount of coal you expect him to name his price. What it costs him to figure a price you are not interested in. If he set an estimating charge you couldn't tell whether it was fair or not. You wouldn't care to be bothered with separate payments and wouldn't expect that it would result in any economy to you if the coal dealers adopted such a practice.

This example of the coal transaction should point out an important difference in the contracting business. Quantity data is furnished to the coal dealer and he names his price. In contracting, bidders have been doing both the quantity work and the pricing or estimating work. The coal dealer assumes no responsibility as to the amount of coal required. It is your responsibility to order enough to keep you warm during the winter. Contractors, however, have been assuming responsibility for all their quantity work when making bids.

Objections to "Payment"

There are many obstacles in the way of collecting estimating expense job by job. Who is going to determine the proper estimating fee for various classes and sizes of jobs? A uniform rate would not apply to all jobs or to all contractors.

Who is going to pay the fee? the owner, or the architect, or will it be collected and paid through a broker acting for the bidders? If paid by the owner or architect, he will expect all bidders to meet the lowest fee accepted by any bidder. Contractors intent on bidding won't hesitate to bid on that account. They will add the difference to their bids if the fee paid seems too small. That would put matters back where they are now. If collected and paid through a broker acting for the bidders, unless the sanction of the architect and owner is obtained, an injustice is done the owner. If the owner must pay he should know to whom he is paying estimating fees and how many. He will be interested to know what it is costing him.

How are the sub-contractors to receive separate payment for their estimating expense? If it is good for the general contractor, it ought to be extended to the "subs." If a fee

large enough to reimburse the "subs" is paid to the general contractor, what assurance is there that it will be fairly divided among the "subs"? On the other hand might not the "subs" victimize the general contractor by collecting their full allowance from each and all of the general contractors to whom they tendered a bid for any job?

What effect would it have on competition? It would stifle competition. An owner would choose to pay for a minimum number of estimates. It would foster formation of a building trust which could be applied to for all estimates. That, it is useless to say, would not benefit the majority of contractors.

"Bidding" for the Payment

How would an architect or owner know what group of contractors to pay for estimates? They know that some contractors will consider their job attractive and be really desirous of competing for it, but how can they know whom they are? Any contractor, with very little labor, can name a price that would guarantee a fine profit, and some might be tempted to do so if paid $200 or $500 or more for the few hours' labor required to make the estimate. But will that satisfy a building owner or an architect? Is it good business?

If competition is kept open, what will prevent anyone from going into the business of making estimates based on cubage, or some other short-cut method, and collecting the estimating fee?

Contractors would continually know of jobs that they would like to bid upon, but had not been offered an estimating charge for doing so. Do you think that would stop them from bidding, or would stop an architect or owner from considering their bids if they were responsible parties? Most certainly not; and if an owner could get good bids without separate payment for estimating expense, do you think he will pay for others that would be no better?

The contradictory situation would arise where a contractor who wanted to figure a job would beg for the opportunity and at the same time demand to be paid for the privilege.

Quantity Expense Real Factor

True estimating expense, separated and not confused with quantity expense, is a small matter. It is better left as an item of overhead. Estimating cannot be delegated to an outsider. It is too personal, and comprehends the assumption of risks and responsibility based on experience and judgment. Consequently, leave it in overhead, along with rent, interest, bad bills, etc. There is no more reason for separating estimating on buildings than there is to separate the coal dealer's estimating expense from the price of a ton of coal.

It is true that contractors cannot, under prevailing methods, give a price for a building as simply as a dealer can for coal. He must find out what is going into a building. That involves the matter of quantity expense and the risks carried therewith. An analysis of that part of a contractor's work will develop the real reason for the demand and agitation for relief, and will dispel some of the confusion that exists.

The liquidator of the defunct Rock and Power Machinery Ltd. has made his final report, in which he announces that $11,767 has been paid on secured and preferred claims, but that there will be no dividend whatever for ordinary creditors. The principal asset available for ordinary creditors was a contract with the Kennedy Engineering Co., he states, but as the creditors declined to furnish the necessary funds for litigation, the claim was abandoned.

The executive committee of the American Association of Engineers has rendered a decision that the constitution of the association does not prohibit the admission of architects, and announces that the applications of architects will now be considered as having the same status as applications from engineers. Those architects who have previously applied for membership and whose applications could not be accepted on account of the apparent exclusion of architects by the constitution, may re-enter their applications for membership.

HIGHWAYS TO LOWER THE HIGH COST OF LIVING

By John S. Beall
President, Armco Iron Culvert & Flume Manufacturers' Association

To say that unimproved roads increase the cost of living is to give a reason without a remedy. Economists are raising their voices against waste and mismanagement, both of which undoubtedly add to the fast-mounting cost of everything we eat and wear. To-day, we hear that blame should be placed upon the middleman; yesterday the effect of the world war was proclaimed the reason for high prices; tomorrow we will hear that the high cost of everything is due to some other single cause. But in my opinion, the high cost of living to-day is due to a combination of causes, no one of which is altogether to blame.

When we consider that following every great war, with its necessarily vast destruction of property and slowing up of production, prices rise and the cost of living consequently increases beyond the income of the average person, we must look behind the alleged causes which are to-day said to be making prices high, and get down to the fundamental causes which made living higher than it should have been before the great social and economic disturbance which resulted from the world conflict. In other words, we must find out what made living as high as it was before 1914.

Trucks Compete with Railroads

People never kick about the price of a thing if they can afford to buy it. It is only when the price of a commodity rises beyond the amount of money they can afford to pay for that commodity that we hear cries of profiteering and witness social unrest, such as is sweeping the country to-day.

The last fifty years have seen the growth of huge cities in the central west and west, and a consequent concentration of population in these cities. Where eggs were six cents a dozen fifty years ago, they now cost fifty-six cents. Where they were eaten fresh from the barnyard fifty years ago, they are to-day transported to cities, placed in cold storage and later, months later, sold to the consumer when he has fifty-six cents which he can afford to devote to the purchase of this food. The farmer who once "drove to town" with his load of eggs, has now been pushed, by the growth of cities, many miles from the city markets and depends upon the railroads to carry his product to where he can receive a high enough price to allow him to carry on his farming business and supply himself and his family with the necessities of life—necessities he cannot himself produce, if he is to maintain his farm at its maximum production.

Just as the railroad seemed to make the farmer independent of the highway, so is the motor truck developing to make the producer of foodstuffs independent of the railroad. The railroad, however, is an organization owning the rolling stock and tracks over which the cars are operated, while the motor-truck owner is often an independent unit, operating over a road controlled by the money of every road bond-buyer and taxpayer in his community, and the communities through which he must pass if he transports his product by motor truck to market.

Municipal Markets

It has been said that the cost of food has *not* been greatly lowered in eastern cities, where farmers, either single or co-operating, transport their products by truck from farm to market. This is true where the farmer sells to the wholesaler, and the wholesaler sells to the retailer who, in turn, sells to the customer, who is the ultimate consumer. By this method only the high freight and express rates of the railroad are eliminated, and these are replaced by the cost of motor transport.

But where municipal retail markets have been established, the cost of food products has been materially lowered. The farmer drives in with his produce and sells direct to the consumer. Many cities are developing these municipal markets, where those who cannot afford to pay the high prices charged by the retailer, and made necessary by the number

of hands through which the products pass, can purchase on the cash and carry plan.

The recent seizures of food products, under the war-time food laws, has turned the attention of the public toward cold-storage methods. The food hoarder is threatened with jail; the food controller or "packer" is being condemned, and drastic laws are being advocated to regulate monopoly and the withholding of products from the market by storing them.

Until production gets back to normal, and supply and demand are to some extent regulated by the completion of the reconstruction period through which we are now passing, we cannot hope for greatly lowered prices. But we can turn our minds to-day toward the construction of the necessary works which the present high prices and unstable conditions have made us realize played a big part in bringing about the situation which now confronts us. Governments, states and provinces have realized this, and we see evidence of their activity in the great, road-building plans now in operation or under consideration, the vast amount of money set aside for road construction purposes, and the active advocation of suitable legislation to bring about nation-wide systems of improved highways.

Proposed Federal Control

Conspicuous among the highway legislation now before the United States congress, is a bill pending in the senate which was introduced by Senator Townsend, chairman of the Committee on Post Offices and Post Roads. It is proposed in this measure to create a vast system of highways under federal control and maintenance. This system will embrace not less than 2%, or more than 5% of the mileage in actual use in each state.

What will such a system, when completed, mean to the people? For one thing which is fundamental—yet which has been long neglected and never properly considered—it will bring our food-producing areas nearer to our manufacturing centres. This means that the vast numbers of people engaged in manufacturing will, with proper legislation designed to bring about the condition, pay less for the food they eat and for everything that is produced by nature to feed the wheels of industry.

Saves Middleman's Profits

The man who lives on the highway and produces food products along the highway, will benefit by highway improvement chiefly because (if he transports his product direct to the consumer in the city via the municipal market or direct to the home), he will have the benefit of the profit now paid to the railroad company, the middleman, the cold storage plant and the retailer. In this way the farmer can get much more for his products than he receives at the present time and still sell them to the public at a lower price.

From this brief survey it is clear that the improvement of roads should be the concern of every person, whether he be laborer, farmer, merchant, banker, doctor, lawyer or otherwise, living either in the city or in the country.

The improvement of highways is a definite, fundamental step toward decreasing the high cost of living. It is something which needs no investigation to prove necessary. Let us put our shoulder to the wheel and roll the mud holes into better roads.

The Winnipeg Aqueduct Construction Co. has agreed to settle all claims against the Greater Winnipeg Water District upon the understanding that the district will pay $2,339 rebate on freight charges. Claims amounting to over $100,000 have thereby been dropped by the company.

The "Committee on Development" of the American Institute of Electrical Engineers has recommended that there be inaugurated the custom of periodically holding an engineering congress, the delegates to which should be selected from all parts of the United States under a plan to be devised for suitable representation, this congress to consider and take action on such matters of general interest to engineers and the public as may merit its attention and as have been previously advertised for a sufficient length of time to permit local organizations of engineers to consider them and to send instructed delegates.

SIGNIFICANCE OF CRACKS IN REINFORCED CONCRETE CONSTRUCTION*

By Stanley H. Harris

CRACKS frequently occur in reinforced concrete structures as in every other form of masonry construction. These cracks are generally due to one or more of the following five causes: (1) Cracking due to contraction of concrete in setting; (2) cracking due to expansion and contraction, caused by temperature changes in the concrete; (3) cracking due to too early removal of forms; (4) cracking due to overloading of the structure; (5) cracking due to settlement of supports.

When concrete sets in air it has a tendency to shrink or contract, and the richer in cement the concrete is, the greater the tendency to shrinkage and cracking. The shrinkage varies from 0.15% to 0.2% of the length for neat cement, and from 0.03% to 0.05% for concrete poor in cement. Although the strength of concrete increases with the amount of cement in it, too much cement, on the other hand, will cause frequent contraction cracks, which tend to neutralize any gain in tensile strength due to extra cement. This is a point which should be borne in mind when designing structures to hold water or other liquids. In these structures all the tensile stresses should be taken by the steel, and it is of the greatest importance to have a concrete which is dense and not liable to contraction cracking. A 1:2:4 concrete, made of properly-graded materials, will be sufficiently strong and dense for most tank work, and is likely to develop less contraction cracks than a richer mix.

Minor Temperature Cracks Unimportant

Cracking frequently occurs through expansion and contraction, due to temperature changes, especially in those parts of the structure which are exposed to the sun and weather, such as roofs and external walls. A great deal of this cracking can be minimized by the adequate provision of temperature steel, but within limits a certain number of minor temperature cracks are inevitable, and should be recognized as inevitable. They are unsightly, perhaps, but as a rule do not affect the strength of the structure.

Removal of forms too soon, produces cracks in floors and weak spots in walls. In the case of floors, if the forms are removed too soon slight settlement occurs, and the soffits of beams and the slabs develop fine hair cracks. In the case of walls there may be no visible sign of any injury, but they often divide at places in their thickness, which may be ascertained by tapping them with a piece of wood or metal, when the hollow sound produced is evidence of the result. Cracking due to this cause should never occur if the job is properly supervised.

Causes of Serious Cracks

Overloading of the structure or considerable settlement of supports produces the most serious cracks; in fact, they are usually the only kind of cracks of any considerable moment occurring in concrete structures. Cracks due to this cause usually occur as fractures in columns or as diagonal fractures in main or secondary beams. If such cracks occur, steps should be taken to remove the load and to strengthen the members affected. Sudden failure is not likely to occur immediately on the appearance of such cracks, as beams and columns generally will carry a lot more load after the first appearance of cracks, before final failure takes place. The appearance of these cracks, however, is often an indication that the member is overstrained.

In estimating the significance of cracks, some attention might profitably be given to what we might call "the eye of the observer." A mere hair crack in the eye of one observer is a chasm in the eye of his neighbor. It might truly be said that nature abhors an uncracked structure almost as much as she abhors a vacuum. No building has yet been devised by the mind of man and erected with his hands which does not have cracks, but their appearance in

*From the proceedings of the Royal Victorian Institute of Architects.

a reinforced concrete structure often arouses a quite unnatural malignity in the mind of some observers towards this long-suffering material. The philosophical reason for this would appear to be that a concrete surface invites the eye to hope for an unbroken plane, and then some untoward and unknown cause intervenes to produces a crack, and the eye and mind feel themselves tricked. All structures, even of the most monumental marble or masonry, have cracks equally with concrete; but, whereas reinforced concrete is monolithic and jointless in its character, all other constructions in masonry or marble are discontinuous and jointed. The result is this—that the cracks produced by movement in an ordinary jointed structure are dissipated, and spread over the innumerable beds and joints of the construction, but in a concrete structure they are apt, unless the steel reinforcement is sufficient and properly disposed, to concentrate themselves in well-defined and sometimes ugly openings. Very slight movements in the foundations of a reinforced concrete structure will often produce cracks which in appearance are out of all proportion to their significance. Such cracks, as a rule, do not affect in the slightest degree the stability of the structure, and are no greater in their totality than the numerous smaller cracks to be found in the joints of any brick or stone structure.

In a properly designed and constructed reinforced concrete structure there should never be serious cracks in the main structural members, and where there are no such cracks in these members, any cracks in the slabs supported by them are generally quite trivial, from the point of view of structural significance. Much worry would be saved by many architects and engineers if this were recognized and frankly accepted. Anyone promising to erect a large concrete structure which shall not have shrinkage and temperature cracks, merely engenders hopes which rarely come to flower. However, a great deal can be done to minimize these cracks in floor slabs by providing sufficient steel over the supports to resist the negative bending movements and by providing sufficient steel to counteract temperature and shrinkage effects.

An Australian Case

As an example of a large reinforced concrete structure containing big masses of concrete exposed to the sun and weather, we might mention the reinforced concrete dome over the Melbourne Library. At the time of its construction, in 1909, it was the biggest reinforced concrete dome in the world, the inscribed diameter being 115 ft., and the circumscribed diameter, 126 ft.

The detailed design of the reinforced-concrete dome over the Melbourne Library was prepared by the Trussed Concrete Steel Co., of England, to the requirements of the architects, Bates, Peebles & Smart, and the reinforcement, in the form of Kahn rib and Kahn trussed bars, was sent out from England all ready for fixing in the work.

In constructing the Melbourne dome, one complete rib on each side of the lantern ring was concreted in one day, together with part of the roof slab on each side of the dome ribs. The remainder of the roof slabs and purlins was filled in some days after the completion of the main ribs, as it was found impracticable to complete the concreting in one continuous operation. The result of this was that the concrete in the ribs had set fairly hard and contracted before the concrete in some of the roof slabs was poured, so that when this latter concrete set and contracted, it pulled away slightly from the flanges of the ribs in spite of steel placed in the flanges of the ribs and concreted into the roof slab with the idea of preventing it. Some years after completion of the dome the junction of the roof slab and flange of the dome rib was visible, showing in a distinct crack. The appearance of these cracks, running parallel with the reinforcement in the roof slab, does not affect the stability of the dome in the slightest degree.

The dome is octagonal in plan, and consists of eight angle ribs, and eight intermediate ribs restrained at the top by the lantern ring, and at the base by a continuous band of steel running around the top of the brick octagon which supports it. The dome is designed to be completely stable between the limits of the bottom ring of steel and the lantern ring, but for the sake of appearance, and also to add some extra stiffening to the ribs, they are continued past the bottom tension ring, across the flat annular roof, running around the dome in the form of deep concrete abutments. The abutments have an arched opening through them, and in each arch small cracks have developed, being most marked at the angle buttresses. These cracks are not as big as cracks often seen in brick railway arches carrying main-line traffic, and appear to be due to the combined effect of shrinkage and temperature both in the concrete and in the brick octagon underneath the dome, which is 114 ft. high to the springing of the dome. As the part of the dome in which these cracks appear is merely ornamental, they have no influence on the stability of the structure. In addition to these cracks, slight cracks have appeared in the ring around the base of the dome. The concrete ring, containing the continuous steel band, is a great mass of concrete having a cross-sectional area of about 20 sq. ft. From the nature of concrete it stands to reason that some cracking must occur in such a large ring, due to contraction and temperature effects. Since the thrusts from the rib are taken by the steel band contained in the concrete ring running around the base of the dome, the small amount of contraction and temperature cracking in the concrete ring cannot affect the stability of the dome as long as the adhesion of the concrete to the steel is not impaired.

A structure such as this, exposed to all the effects of wind, weather and temperature, must of necessity move or breathe under their action, and it would have been against the nature of things if no cracks had occurred.

Cracks Foreseen by Designers

At the corner ribs the thrust is transferred to the main tension ring by means of steel stirrups made of ¾-in. square steel-rib bars. It was at first thought that some of the cracking in the concrete work was due to these members not acting efficiently. It was therefore decided to construct a model of this part of the dome, one-sixth full size, and test it to destruction. The results of this test showed that not only did these members transmit the load efficiently, but actually strangled themselves in their efforts to transmit the loads. The stresses in the concrete and steel of the main members, taking into account temperature effects, were also investigated, and were found to be very low. The cracking, therefore, was found to be almost entirely due to the effects of contraction and variations of temperature, and that such cracking would occur was foreseen by the designers of the dome, and pointed out before construction was begin.

Where big concrete structures of this sort, exposed to the weather and temperature variations, are built, it is always advisable to place a false ceiling under the structure rather than plaster the ceiling directly on to the concrete work. Breathing movements must occur in such structures, and then the ceiling may crack and bits fall off, unless a false ceiling is provided.

United States Engineering Council has addressed a letter to the president of the United States urging that a board of surveys and maps be appointed, consisting of a representative from each of the present United States map-making agencies, together with representatives from well qualified map-using agencies, and that this board be invested with authority to devise a plan of standardization and co-ordination of the map work of the United States government and report same to the president for such action as he may find wise. Engineering Council states that at present the United States Geological Survey is the principle map-making agency of the United States government, but there are many other agencies of that government employed in similar work. Engineering Council states that a complete topographical map of the country would be very useful in the location of railways and highways; plans and location of drainage and water supply projects; prosecution of geological, soil and forest surveys; development of water powers; installation of electrical power lines; construction and maintenance of inland waterways; location of reservoir sites for flood prevention and water conservation; etc.

WATER DEPARTMENTS AND PRIVATE FIRE LINES*

Proper Regulations Governing Private Fire Protection Lines —Suggestions for Compensation—Contamination of Water Supply—References to Court Decisions

By Dow R. Gwinn
Terre Haute, Ind.

IN considering fire protection, there should be no confusion between that which is furnished by the municipality, known as public fire protection, and that which is for the exclusive use of all individual or manufacturing concerns. In the first case, the pipes and hydrants are on public streets, while in the second case large pipes are laid into private grounds and buildings to which are connected fire hydrants, automatic sprinklers, and stand pipes. The manufacturer who desires something more than the public fire protection should, of course, pay for private protection of a special character. A comparison could be made with the public police protection furnished by the municipality and that of a manufacturer paying for a private watchman or police. The municipality provides fire and police protection of a general character for the public. If special protection of a private character is desired, the cost is met by those who enjoy the special privileges. It is not necessary in every case to connect with the city water mains to enjoy private fire protection.

Protection by Independent Plants

This protection can be provided by means of independent or local equipment, such as fire pumps and elevated tanks. A number of manufacturing concerns now provide their own special fire protection in this way and in such cases they pay the actual cost of the same. This cost includes interest on the investment, depreciation, repairs, taxes, fuel used in maintaining steam, extra labor in looking after fire pumps, and also additional labor on Sundays, holidays and at such times as the factory may be shut down. It has been estimated by an insurance expert that the cost of such special private fire protection when furnished by the manufacturer would amount, in one particular case, to approximately $600 per annum.

Special Connections With Mains

This service is furnished in cases where the manufacturer does not wish to make the investment for fire pumps, etc., and to employ men to keep up steam on holidays, Sundays and such times as the factory may be shut down. Connections with public water supply should not be made with private pumping plants having other sources of supplies than that furnished to the general public. Typhoid fever epidemics have resulted in several cities on account of private fire lines being connected with the public water supply and also with contaminated sources through private fire lines. In the city of Lowell, Mass., I understand there were about 25 deaths; in Auburn, N.Y., there was a small epidemic; in Rockford, Ill., there were 40 deaths, although it is said that it was not clearly proven that the fire line connection was to blame. It is reported that typhoid fever epidemics have been caused by fire pumps draughting from polluted sources and seeping through leaky check valves into public mains at Sheboygan, Wis., and Morris, Ill. The public health is of such great importance and human life is so precious that no connections should be made between the public water supply by means of private fire lines and other sources of supply.

Where connections are made with a public water supply for private fire protection, there is a menace to the remainder of the city on account of danger of broken sprinkler pipes; there are a number of cases on record where the automatic sprinklers have failed to control the fire and falling walls have broken the large supply pipes, making it impossible for the water works to maintain adequate fire pressure. With a 6-inch supply pipe discharging a full stream, it would be practically impossible for the average water works plant furnishing water under direct pressure to supply adequate fire protection for a second fire in case one should break out at that time. The result of a broken sprinkler pipe might mean a serious conflagration and destruction of a large portion of the city.

It is the opinion of the author that insurance companies will realize this menace before many years have passed and will discourage if not prohibit large connections between the water mains and automatic sprinklers. At the present time, the Committee on Fire Protection of the National Board of Fire Underwriters recommend in congested valued districts, a supply of 7,500 gallons per minute in excess of the domestic consumption and state that this includes an allowance for loss from broken services, elevator, and sprinkler connections incidental to a large fire. This means that in order to provide fire protection which is considered adequate by the underwriters, it is necessary for the water department or company to provide equipment and mains sufficient to take care of a demand on account of broken sprinkler connections. This means an extra investment or cost to the water department or company. If such connections are furnished, the water department or company should receive just and reasonable compensation for such special service.

There should be no question in regard to the right to furnish this service by meter measurement and there should be no connections allowed unless the same are provided with meters. The meters for this purpose should, of course, be subject to the approval of the water department or company. In most cases, they should be meters which have been specially designed for fire lines, although there are cases where a compound meter would be satisfactory.

Suggestions for Compensation

(1) On the basis of the saved insurance premiums. These savings due to automatic sprinklers amount, in some cases, from $1,800 to $3,000 per annum. If the water department or company furnishes the service by which reductions in insurance rates are made, the compensation should be adequate. The reduction in insurance rates on account of automatic sprinklers in one particular case was from $1.60 per hundred to 20 cents.

(2) The compensation should be equal to the cost to the consumer if such special fire service was furnished independently. This will, of course, include interest on investment, repairs, taxes, fuel, extra labor, etc.

(3) Compensation to the water department or company on account of large mains, additional equipment, etc., necessary to provide adequate service to the manufacturer, and also for maintaining pressure and standing guard over premises of the manufacturer; under this arrangement, there should be a minimum meter rate on the basis of the size of the meter, in proportion to the minimum rates charged for ordinary house meters. Where the water department is standing by, maintaining pressure on the premises of the manufacturer, the compensation should be adequate for such unusual and valuable service.

Rules for Private Installations

1. All private fire protection services will be installed by the company, which will ascertain the best location for same, and lay the pipe from the street main to a point just inside the wall of the building, or within the building line of open yards, where buildings are set back from the building line. The consumer will be charged for time and material, plus 10 per cent.

Size of Service Pipe

2. In all cases, the company shall decide the size of the service pipe. In all cases where underwriters' pumps are to be installed, a suction pipe of sufficient internal area to deliver a quantity of water equal to the full rated capacity of the pipe will be allowed, and no enlargement of said suction pipe inside of the premises will be permitted. If, however, this service pipe is run to a surge tank placed in

*Excerpts from paper read before twelfth annual meeting of the Indiana Sanitary and Water Supply Association.

close proximity to the pump, the full size of suction which the pump calls for may be run from the pump to the tank.

3. One service only will be allowed to any one building or premises, unless in the opinion of the company, the general or public fire protection will not be jeopardized and more than one is absolutely necessary for the proper protection of the premises. All fire equipment connected to the company's service shall be confined within the building or on the premises named in the application, and where two or more connections are made for one building or premises, they shall be kept separated, unless special permission is obtained from the company to connect the same in a manner to be approved by it.

Test of Fire Services

4. Whenever a fire service system is to be tested under the regulations of the fire insurance underwriters, the consumer must notify the company of such proposed test, naming the day and hour when the same is intended to be made, so that, if desired, the company may have an inspector present during the test.

Contamination of Water Supply

5. Any fire protection system supplied with water from the company's service shall be supplied exclusively with such water, and no connection will be allowed with any other system drawing its supply from any other source whereby the company's water supply may be contaminated by the failure to close valves, or leaking check valves, etc., and no auxiliary or secondary suction pipe to any underwriters' pump taking water from wells, streams, or other source whatever, will be permitted. Any fire protection system using water from wells, streams, or other source than the company's service shall be kept separate from any such system supplied from the company's service.

Inspection

6. All fire services shall be subject to inspection by the company from time to time, and the consumer shall give the inspectors all reasonable facilities for making the inspections, and any information concerning the same that the inspector or the company may require. Care will always be taken that inspections will be made with as little inconvenience to the consumer or occupant as possible.

Approval of Fire Chief

7. All applications for private fire protection shall be subject to the written approval of the chief of the fire department of the city, who in such approval, shall state that, in his opinion, the public fire protection will not be endangered by the connection proposed to be made by the company, when properly safeguarded by the placing of an indicator post valve as near the main as possible, said valve to be under the control and orders of the chief of fire department at time of fires, with full authority to close said valve.

Guarantees

8. The company or department in no manner guarantees to furnish a proper quantity of water through fire protection services, nor does it undertake to guarantee anything relative to such service, but it will endeavor to maintain the efficiency of its service under all conditions. The granting of a permit for private fire protection is under the express condition that the company shall not be considered or deemed in any manner to have undertaken to extinguish fire or to protect any person or property against loss or damage by fire or otherwise, the said company not being an insurer of persons or property, and that it shall be free and exempt from any and all claims for damages on account of any injury to persons or property by reason of fire, water, failure to supply water or pressure, or for any other cause whatsoever, and that in the event of the destruction of the premises of the consumer, then the contract between the company and the consumer shall immediately cease.

Plans and Drawings

9. The consumer will furnish an accurate sketch showing the pipes, valves, hydrants, connections, and appurtenances on the premises of the consumer and connected with the mains of the company and also an accurate sketch of any other water pipe system and fixtures that may exist on the premises.

Excerpts from Court Decision

"The principal object of the defendant's water board in requiring fire service pipes to be metered is to prevent the surreptitious or careless withdrawal of water through such pipes for other purposes than the extinguishment of fires; another object is to procure the measurement by meter of all water consumed for any purpose in order to check wastage and to require each taker to pay for the exact quantity of water furnished to him. . . .

"Both upon principle and authority we are of opinion that under circumstances like those before us it is not unreasonable to require the installation of a meter at the plaintiff's own expense in its private fire service pipes.

"Nor can it be said that this regulation imposes undue burden upon the plaintiff. The defendant has afforded reasonable means of extinguishing fires by public hydrants; if the plaintiff desires in addition a private system for the protection of its own buildings, it is not unfair for the defendant to impose, as a condition of supplying without other charge water to make this system available, the requirement that the plaintiff shall take this water only through a meter to be put in at the plaintiff's expense." Shaw Stocking Company vs. City of Lowell. (Supreme Judicial Court of Massachusetts; Middlesex, May 2nd, 1908. 85 Northeastern Reporter, 90.)

Public Service Commission's Ruling

"These authorities are cited to show the views of courts of high authority, and for the further reason that they are in harmony with the conviction of all men who have thought seriously upon this subject. There is no perceptible reason why the water company should be compelled to provide and maintain a sufficient supply of water to operate the water sprinklers in time of fire for private individuals, without compensation. On the contrary, this special benefit to the property owner over and above what the municipal fire protection affords the people in common, should be paid by the private user." Indiana Public Service Commission in the case of Commercial Club of Terre Haute, vs. Terre Haute Water Works Company, decided December 18th, 1915.

"The proprietor of a building, who installed therein an automatic sprinkler system, intending thereby to put out fires before they could gain headway, derives benefit from the system in fire protection and reduced insurance rates, and though there be a general benefit in reducing fire hazards, yet a municipal water works system to which the sprinkler is attached performs a service, and stands ready to perform others for which charges may be made.

"It is evident that payment for the small quantity of water used would be wholly inadequate as compensation for the pressure required, and the readiness at all times to serve and the inspection by the city which might well be exacted." Edgerly vs. City of Ottumwa, 156 N. W. 388, decided February, 1916, by the Supreme Court of Iowa.

Action to restrain city from placing a meter on fire extinguishing plant dismissed by Appellate Division of the Supreme Court. Judgment affirmed with costs. American Manufacturing Co., Appellant vs. City of New York. Court of Appeals of N.Y., January 27th, 1911.

Entitled to Reasonable Compensation

"A water company which supplies the pressure and water for an automatic sprinkler for a private corporation performs a service which is not included under its contract with the city to supply water for fire protection and has the right to make a reasonable charge therefore against the corporation." D. B. Loveman Co. vs. City Water Co. 1 Tenn. Ch. App. 596.

"In the matter of furnishing water to its citizens, a city when authorized by its charter acts in a private rather than a governmental capacity and has the same right to make reasonable charges therefore that a private corpora-

tion has when serving the public." St. Louis Brewing Association vs. City of St. Louis, 140 Mo. 419—37 S. W. 525. 41 S. W. 911.

"A rule providing that water meters might be installed at the pleasure of the water board on the consumer and that after they had once been installed, the consumer could not thereafter return to the flat rate is reasonable and may be enforced where the meter rates are reasonable and no discrimination between consumers is shown." Powell vs. Duluth. 97 N. W. 450.

"The law imposes no duty to insure the property or extinguish fires." Woodberry vs. Tampa Water Co. 57 Fla. 243, 49, So. 556.

The Arizona Commission in fixing rates to be paid to a water company, decided that a mining company desiring a private fire protection system, should be required to pay a fixed demand charge although "the actual water consumed for this purpose is likely to be negligible." Arizona Corp. Com. vs. Morenci Water Co., Public Utilities Reports, 1915, C. 525, 527.

SOME LESSONS AND PROBLEMS*

By F. W. Bricknell
City Engineer, Hull, Eng.

IT may be useful to consider in what way and to what extent the war has left its mark on municipal work.

All the usual services have, of course, been badly hit by the scarcity of labor and material, so much so that, locally at any rate, prices have hardly needed to be considered.

Taking these services in detail, highway maintenance has probably called for the most criticism from the general public. Here the necessity for deferring repairs far beyond ordinary practice has given an opportunity for verifying pre-war opinions.

There was nothing left to learn about granite-sett paving, and scarcely any repairs have been necessary during the war.

Paving Experiences

In regard to wood paving, there has been more cause than ever to regret the extensive adoption of Australian wood, and it could almost be said that the paving with Petrograd redwood has caused no anxiety at all, and will require comparatively little attention before the Australian wood is replaced. About 160 standards of Petrograd deal, purchased in 1915, served for urgent replacements until the middle of 1918, and since that time English oak and larch have been used; but, wherever possible, the old blocks have been turned and relaid on a "soft bed." English larch offers considerable promise as a paving wood. It takes creosote unevenly, and some has been laid without creosoting, but that now in use is being creosoted by the Rueping process. The oak used is, of course, not from long planks, but from "offcuts" and billets.

The Trinidad asphalt paving, referred to in the writer's 1916 paper, has given general satisfaction, and this paving, now known as "Lithocrete," has been selected for the streets to be paved under the "Road and Bridge Program, 1919-20." There were special and local reasons for preferring this paving to the less expensive two-coat work.

Many macadam roads have become less comfortable for cyclists, but none have caused serious complaints. The situation has, in fact, been saved by tar-spraying, and the writer sees no reason to change the opinion he expressed in 1916 that, except where heavy rubber-tired traffic has to be carried, water-bound whinstone macadam, tar-sprayed annually, is far preferable to tar-macadam.

Welding Tramway Rails

The tramways have fully justified the ideas of their designer, the late Mr. White; but rails which have been eighteen to twenty years under traffic are naturally showing wear at the joints. Up to 1916 it had been the practice to pack up a hammered joint until the lowest part was at normal level and then to dress off the projecting portion. This would, of course, eventually have destroyed the rail head, and in 1916 acetylene welding was adopted. In 1918 acetylene supplies were so difficult to obtain that an arc welding set was purchased, and although this involves night work, it seems likely to supersede acetylene, as, so far as can be judged at present, the results are more permanent.

The value of the close anchorage of the rails is very plainly seen now that some of the holding-down bolts have given way. At such places a pumping action is set up with more or less subsidence of the rail.

Of new developments during the war it is only necessary to mention food production and national kitchens.

Allotments and War Gardens

While every possible effort was made to obtain additional allotments, it was necessary to accommodate about 1,850 applicants on war plots. With one or two unimportant exceptions the owners of the land gave every encouragement, and no rent was paid by the corporation except for land already earning rent. For the most part the plots were let off in batches to a "principal tenant," who paid an acknowledgment of one shilling. In most cases the tenants did all their own work, but in some cases fencing, drainage, etc., was done and an additional rent charged.

The difficulty with regard to allotments proper was that all suitable land was regarded as ripe for building, and the owners would not tie it up for a period of years. It was found, however, that tenants were quite willing to take the risk of disturbance for building, and a number of leases were entered into for periods up to ten years, with a provision that the owner may resume possession at short notice for *bona-fide* building development without payment of compensation. After a time an officious person discovered that tenants could not contract out of the Act, and since that time no further land has been taken. The total area leased during the war was about 170 acres, let off to about 2,176 tenants. The rent paid by the corporation varies from £2 10s. to £5 per acre, and after paying for fencing, drainage, road-making and water supply, it is necesary to charge rents varying from 10s. to 12s. 6d. for a plot of $\frac{1}{16}$ acre.

Every possible assistance has been given to occupiers in the way of free literature, lectures and advice, the supply of manures and lime at wholesale prices, and the spraying of potatoes at less than cost.

National Kitchens

While it is to be hoped that no lesson is required for the future, it is probable that existing national kitchens have a long life before them, and there is no doubt that in many districts their catering offers a welcome relief from the intolerably bad private catering.

The principal point of interest about the Hull kitchens is the policy which was pursued of taking over existing shops which were finding a difficulty in obtaining supplies and installing the tenants as managers. Generally speaking the arrangement has been a great success, one branch in particular yielding very large profits. The policy fell short of obtaining the best results because, on the one hand, it was not fully developed before the need was past, and not enough branches were opened to keep the central kitchen fully occupned; on the other hand, the branches needed a supply of confectionery and sundries to keep them occupied for the full day, and it was only after considerable delay that a bakery was rented and set to work for this purpose. The committee has, however, every reason to congratulate itself on the success of its policy, and it is all to the good that when times become normal their managers will be able to resume their old businesses with improved premises, wider custom, and some useful lessons.

Turning to the future, there are three sets of problems which are exercising the minds of most municipal engineers. The most conspicuous of these is, of course, housing, as to which the writer does not feel himself in a position to speak, as his connection with it is confined to the construction of streets and sewers. Here it is necessary to face those problems of routine work which are concerned with giving the ratepayer satisfactory services at not too great an increase

*Paper read before the Institution of Municipal and County Engineers, July 26th, 1919, in Hull, England.

on the old prices, and the means of doing so will be discussed later. Meanwhile, the writer would emphasize the importance of making each scheme part of a town-planning scheme, and avoiding the isolation which has been the bane of private estate work in the past.

Next, and probably the most attractive subject, is the flood of new works which has been held up by the war, all of which works have earnest advocates, each of whom is anxious that his pet scheme shall have preference over all others. If a small proportion of the Hull schemes materialize the writer will have an interesting time, and there will be good material for another visit of the institution. It remains to be seen how far the financial condition of the country will allow the schemes to materialize.

Use of Machinery

The third problem, and that to which I wish to direct the special attention of members, is that of bringing the cost of routine work and also that of street and sewer construction to such a figure as can be covered by a not intolerable increase of the rates. With average weekly wages doubled, cost of materials more than doubled, and assessments stationary, it is difficult to see how the doubling of rates can be avoided, and it might be said that the ratepayer has no right to expect it, but he is at any rate entitled to an effort.

The first cost to be attacked is that of labor. The old class of navvy and horseman, who was recruited from the country, has almost disappeared from the towns, and most of those who are in the towns can find easier and better-paid employment than that offered by a municipal body. The townsman has an inferior capacity for heavy work and a very strong prejudice against it. The obvious policy, therefore, is by some means to cut out the heavy work and endevor to staff public works with men who will use their heads. A simple example is the use of scarifiers to break up macadam roads. Formerly these were not used in Hull because they would displace labor. Now they have to be used, because pick-work is unpopular. If all increase of costs could be met as easily as this there would be no scope for a discussion.

Problems in Mechanical Loading

In view of the urgency of housing work and the shortage of navvies, the writer has looked into the question of using trenching machines for the sewer and gas, etc., trenches in the new streets. At the time of writing the economy of such a machine for the amount of work required at Hull is doubtful. One cannot propertly adopt the usual practice of debiting the work with a percentage for interest and depreciation, but must charge the whole cost of the machine to the rush of work for which it is purchased. Before this paper is read no doubt some additional light will be thrown by Mr. Collins' paper at the general meeting.

A much simpler proposition is a tamping machine. The first cost is comparatively small, and not only should there be a saving in working expenses, but there should be an efficiency which was lamentably wanting in hand-work.

The loading of vehicles is work which cries out loudly for mechanical assistance. Costly vehicles are kept standing when they might be running, and good horsemen and motormen are lost because, being good, they can obtain work in connection with mills, etc., where they do not have to handle their loads. The writer has been able to obtain the use of high-level coal cells, and to obtain delivery of a certain amount of road metal and fuel in hopper wagons, which is an admirable solution so far as it goes. Some material landed at wharves by crane can be taken direct to its destination, but there remains a great deal which has to be picked up in the yard and elsewhere. There are some inexpensive mechanical loaders which deal well with dry macadam, gravel, etc.; but tarred material is a problem, and destructor clinker is even more unpopular with the man, and there is more of it. The average cost per ton is probably four times what it was ten years ago.

Improved Road Surfaces

In street cleansing most engineers, no doubt, find that they are already reaping the benefit of past work in improving road surfaces and in tar-spraying. Where a reasonably hard stone has been used, even an untreated water-bound macadam road which has been repaired several times by steam rolling, has a much lower dirt-producing capacity than the old roads of the writer's early days. The partial disappearance of the horse has effected some relief, and for about fifty weeks in the year the only scope for economy seems to lie in substituting single-handed work for gang work in all but the principal streets. During the dirty weather in late winter good use can be made of a picking-up machine, but it must be an inexpensive machine which can be attached to another vehicle. The writer has used Whittome's machine with satisfaction for some years.

Most engineers probably have to continue to use the motive power already at their disposal. In a fairly level town, and for miscellaneous work, there is not a great deal to choose between various types, and the capital cost of mechanical vehicles is a deterrent to their use at the present time. Given plenty of heavy work and suitable loading facilities, steam is by far the most economical. During the war, when the writer was hard pressed for both horse and mechanical drivers, an electric rully was ordered with the idea of employing a man of the navvy type to drive it. A permit was obtained after the armistice, but at the time of writing the rully is not delivered.

Economies in Material

The writer would like to elicit opinions as to economies in material. Most towns have their particular extravagances and parsimonies. In Hull natural flags have benerally been used. There seems to be no justification for continuing to buy them when highly satisfactory artificial flags can be laid at half the price. Wood-paving blocks, where large areas have to be relaid, might be reduced in depth to 3 ins. There are purposes for which concrete can replace other materials, but with cement at the present price the number of purposes is reduced.

The cost of refuse destruction has for long been somewhat of a bugbear to the writer. During the war not only has the cost of wages more than doubled, but the character of the refuse has changed, its calorific value having become almost *nil*, and the so-called clinker increased to about 50 per cent. of the original weight.

In the interest of allotment-holders the corporation was allowed to establish an experimental pulverizing plant which had been held over from the outbreak of war. It is too early to give financial results, but it is safe to say that the cost of treatment is less than burning, and there is no clinker problem; but the small plant dealing with about one-fifth of the refuse easily supplies the present demand for the manure. Such a plant really should be a destructor, as a great deal of large stuff has to be thrown out, especially during "spring cleaning," and has to be destroyed by other means.

If the demand for the manure increases the writer proposes to install a screen at one of the destructors and screen out the small stuff for manure, in the expectation that he will thus get rid of a great deal of the inert matter and obtain better furnace results from the remainder. Meanwhile, he is encouraging the health department, who collect the refuse, to dispose of as much as possible by tipping, and he has no hesitation in defending the practice.

Established Services Severely Treated

It is not to be hoped that any alterations of practice will bring expenditure appreciably nearer its old level, but it is a usual experience that councils handle the estimates for established services much more severely than those for new schemes and new departments. In the hope that the exchange of ideas will enable members to maintain the efficiency of their works in spite of this tendency, the writer has put together his notes with the feeling that their value depends on the extent to which they elicit the ideas of othe

---

Approximately 1,200 houses have been built this year or are now being erected in Ontario under the provisions of the Act granting loans to home-builders. In Ottawa, 120 houses, valued at more than $400,000, are under construction; in Oshawa, 34 houses; in Windsor, 65 houses; and similar renewed activity is being indicated in many other cities.

TORONTO'S SEWAGE DISPOSAL PROBLEM

IN the article on performance of the slow-sand filters at Toronto, which appeared last week in *The Canadian Engineer*, Norman J. Howard, bacteriologist in charge of the filtration plant laboratory, shows that the pollution of Toronto's raw-water supply has increased approximately 62% within the past five years, judging by B. coli tests. Of the 300 days in which examination of the raw water was made during the year 1918, the typical colon-bacillus was present in one cubic centimetre on 121 days.

The continual deterioration of the raw water at Toronto is due to the increase in discharge of sewage into the lake. While this applies not only to Toronto but also to many other neighboring municipalities which are daily discharging large quantities of sewage into the lake, the absence of proper sewage disposal works at Toronto is undoubtedly responsible in a very large degree for the increased pollution. The Morley Avenue sewage disposal plant, which has never operated to the satisfaction of either the municipal authorities or the public, is now reaching the limit of its capacity for even such work as it is doing, and it is said that within a few months it will have exhausted the areas at its disposal for the deposit of sludge.

As the late Theodore Roosevelt remarked several years ago in Buffalo, the people of Canada and the United States should be sufficiently civilized to be able to get rid of their sewage in some other manner than by dumping it into their drinking water.

Toronto, like many other cities, is faced with a sewage disposal problem that may cost a large sum of money before a satisfactory solution is found, but it will be money well spent, for no money can be spent to better advantage than in the improvement of public health, and there is no phase of sanitary work that is of more importance than the protection of water supplies.

Fortunately for Toronto and many other cities, the liquid chlorine plant which was installed a few years ago has proven extremely efficient. That chlorinating plant is the only thing that stands between Toronto and a great increase in the typhoid death rate. The amount of raw sewage that is being poured into the lake, comparatively near the water supply intake, is so polluted with matter of excremental origin that the water could never be filtered so efficiently as to render it entirely innocuous. Moreover, the filtration of such heavily polluted water would cost an enormous sum for coagulant if Toronto's drifting sand filter plant had to be operated every day in the year, and every hour in the day, to the highest possible efficiency. In order to reduce the expense for coagulant, the plant is now being operated, it is said, at a lower efficiency than the filters are capable of showing, and the chlorinating apparatus is being relied upon to sterilize the water, as it has been proven by months of experience that the chlorine treatment ensures sterile water even when the filters are being used only to cleanse the water.

The high efficiency of the chlorine plant, however, does not excuse Toronto from a solution of the sewage disposal problem. It is far safer to prevent pollution of water supplies than to remedy the pollution. There will come a day when the load upon the Toronto filtration and sterilizing plants will be extremely serious unless active measures are taken to solve the sewage disposal problem. The works department of the city of Toronto realizes this, as the works commissioner has been requesting the city council for the past two or three years to authorize the expenditure of $50,000 for sewage disposal experiments, but some of the other civic officials and some of the city councillors have not so thoroughly realized the urgent need for action. Nevertheless it is understood that the department intends at an early date to send an engineer to Milwaukee to reside there for several months in order to study the activated sludge method of sewage disposal in co-operation with T. Chalkley Hatton as consulting engineer; and also that the department intends to experiment with a new English centrifuge for dewatering sewage sludge. It has also been said that Dr. Nasmith, director of laboratories of the health department of Toronto, has under investigation a very promising method of sludge disposal, and his work is being watched with interest by the other Toronto civic officials.

WATER WORKS MONTHLY REPORTS

AS a part of its system of control of water purification plants in Wisconsin, the Board of Health of that state recently issued a report form which must be filled out and returned monthly by the superintendent or operator of every water purification system within the board's jurisdiction.

The form requires a statement of the number of gallons of water pumped, pounds of liquid chlorine or "hypo" used per twenty-four hours, P.P.M. of chlorine used, free chlorine in treated water, bacteria count in raw and treated water at 20 and 37 deg. C., and the B. coil count in raw and treated water in 1cc. and 10cc. This information must be given for every day of the month; also the number of filters used each day, the hours of service of each filter (length of run), the average filtration rate, the loss of head (initial and final) on each filter, the number of washes and number of minutes per wash, the amount of water used for washing, the amount of alum used in pounds and in grains per gallon, the turbidity in P.P.M. in the raw water and in the effluent of each filter, and the alkalinities of the raw and clear water.

If the board can persuade all plants, both large and small, to make a complete return of this information for every day in the year, it will certainly have a valuable record of water supply conditions in that state, but we fear that in connection with the reports from small plants there will be either many blanks or frequent guesses. However, it is the intention of the board to conduct an efficiency run of every plant at least once a year, and that will assist greatly in checking the reports.

Sept. 25, 1919

PERSONALS

DR. GEORGE G. NASMITH, who will be one of the three partners in the newly-formed consulting firm, Gore, Nasmith & Storrie, Toronto, was born December 31st, 1877, in Toronto, Ont. He attended the Wellesley public school and in 1896 graduated from the "Old Grammar School," now the Jarvis Collegiate Institute, and enrolled at the University of Toronto in the natural science course, specializing in geology, chemistry and mineralogy. From 1900 to 1902, he took a post-graduate course in science and physiological chemistry, obtaining the Ph. D. and M.A. degrees. In 1902, Dr. Nasmith joined the Ontario Board of Health as a chemist under Dr. Amyot, and during the following eight years wrote a number of papers on chemical research, including several articles on coal-gas poisoning and water sterilization. A paper upon the latter subject was published in the Royal Army Medical Journal and the method described was later adopted in many places throughout the world. In 1910, Dr. Nasmith became director of laboratories for the health department of the city of Toronto, from which position he is now resigning, the resignation to take effect at the end of the current year. Dr. Nasmith recommended chlorination of the water supply of the city of Toronto at the time of the break in the intake in 1911, and lowered the typhoid death rate from 42 to 20 per 100,000 (which figure has since been reduced to the present rate of approximately 2 per 100,000). It is largely to Dr. Nasmith that credit is due for the elimination of excess water from Toronto's milk supply, saving about $600,000 during the past few years for the people of Toronto. He is the inventor of the brush trickling filter for sewage disposal plants, and is now working upon a solution of the sewage sludge problem. In 1914 Dr. Nasmith went to Valcartier as head of the Hydrological Corps, in charge of water supply, and was requested by Gen. Sir Sam Hughes to go overseas as sanitary adviser to the first Canadian expeditionary force. Dr. Nasmith originated the portable filtration and sterilization unit which was adopted by the British War Office, and was sent to France with the rank of colonel, in charge of the Canadian Mobile Laboratories attached to the First British Army. At the second battle of Ypres he discovered that the gas being used by the enemy was chlorine. He promptly found an antidote and devised a gas mask. For these and other services, on New Year's Day, 1916, he was invested with the Companionship of St. Michael and St. George. Upon his return to Canada, he received the honorary degree of D. Sc. in 1917, and last year he passed the examinations at the University of Toronto for the degree of D.P.H. (Doctor of Public Health).

LT.-COL. A. E. DUBUC, D.S.O., has been appointed by the Department of Railways and Canals, Ottawa, as superintending engineer for the Province of Quebec, to succeed the late Ernest Marceau.

PAUL E. MERCIER, consulting engineer to the city of Montreal, has resigned. Mr. Mercier was appointed deputy chief engineer of the city of Montreal in 1914, and in January, 1916, chief engineer. In May, 1918, he became director of public works, from which position he retired last November to act as consulting engineer to the civic departments.

WILFRED HOLLINGWORTH, of the contracting firm of Brennan & Hollingworth, Hamilton, Ont., has sold his interests in that firm to his partner, W. C. Brennan, and has returned to England. Mr. Hollingworth came to Canada from England several years ago, and for a time was assistant city engineer of Hamilton.

MAJ. L. E. SILCOX is now on the engineering staff of the C.N.R., locating the line west of Bengough, Sask. In 1914 Major Silcox was locating engineer of the Hudson Bay Railway. He and twelve men who were working with him enlisted for overseas service. Seven of them won decorations for gallantry, Major Silcox being awarded the D.S.O., and one was killed.

L. N. EDWARDS, who resigned a few months ago as supervising engineer of bridges, Department of Works, Toronto, in order to accept a position as senior highway bridge engineer with the Bureau of Public Roads, Washington, D.C., has been transferred to Fort Worth, Texas, and will be district engineer in charge of the bureau's bridge work in Mississippi, Arkansas, Oklahoma and Texas.

ELMER LUNDERVILLE, comptroller of the Canadian Ingersoll-Rand Co., Ltd., Sherbrooke, Que., has resigned and has purchased the munition-manufacturing plant of the Norwood Engineering Co. at Cowansville, Que., where he will make a number of engineering specialties after he has equipped the plant with some new machinery. Mr. Lunderville joined the Ingersoll-Rand sales staff about twelve years ago, and was subsequently the firm's purchasing agent for several years.

W. F. V. ATKINSON, chief forester of the Spanish River Pulp & Paper Mills, Ltd., is entering private practice at Sault Ste. Marie, Ont. He will continue his connection with the Spanish River Pulp & Paper Mills, Ltd., in a consulting capacity, and intends also to conduct investigations of natural resources for any other companies who may desire his services in establishing new industries dealing with timber lands and water powers. He will specialize in forest engineering, including water storage and conservation.

TOWN PLANNING INSTITUTE OF CANADA

WITH the co-operation of the Commission of Conservation of Canada, a joint meeting of the American City Planning Institute and the Town Planning Institute of Canada will be held October 17th and 18th at the Chateau Laurier, Ottawa.

The secretary of the congress is Flavel Shurtleff, 19 Congress St., Boston. The assistant secretaries are M. J. Patton, 30 Rideau St., Ottawa; and F. D. Henderson, Topographical Surveys, Ottawa.

The congress will be opened at 2 p.m., October 17th, by addresses of welcome by Hon. N. W. Rowell and Mayor Fisher, of Ottawa. These addresses will be followed by a report of the committee on the fundamental principles of city planning (Frederick Law Olmsted, chairman); a report of the committee on street widths (B. A. Haldeman, chairman); and discussion. After an informal dinner the report of the committee on zoning (Mr. Bassett, chairman) will be presented, followed by discussion.

At. 9.30 a.m., Saturday, October 18th, Morris Knowles will present the report of his committee on the economic design of utilities in streets, and Arthur B. Comey of the committee on lot sub-division. At noon the delegates will be the guests of the Canadian Club at luncheon. The speaker will be C. H. Mitchell, dean of the Faculty of Engineering, University of Toronto, whose subject will be "Reconstruction and Town Planning." In the afternoon the town planners will visit the Parliament Buildings and drive around the city and parks. In the evening Thomas Adams, chairman of the Town Planning Institute of Canada, will present a paper on "Practical Housing," illustrated by moving pictures; and Noulan Cauchon, chairman of the Ottawa branch of the Town Planning Institute of Canada, will read a paper on "The Planning of Ottawa."

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Anderdon Tp., Ont.—Tenders addressed to A. C. Mailloux, township clerk, Amherstburg, Ont., will be received up to 4 p.m., Saturday, September 27th, 1919, for the supply of all materials and the erection of one abutment and two wing walls for the bridge over the Canard River, and placing the said bridge on a level with the highway. Plans and specifications may be seen at J. J. Newman's office, in Windsor, and at the office of the township clerk.

Belleville, Ont.—City council contemplates construction of pavement on Pinnacle St.

Belleville, Ont.—Council contemplates construction of an asphaltic pavement on West Bridge St. from James St. to Octavia St. Estimated cost, $11,000. Granolithic sidewalk on west side of Ann St., estimated cost, $1,582.68. J. G. Mill, city engineer.

Bengough, Man.—Tenders will be received until 12 o'clock noon, October 6th, by the C.N. Ry., for grading and culverts on the Maryfield branch, from Bengough, westerly 17 miles. H. A. Dixon, chief engineer, Winnipeg.

Brantford, Ont.—The Brantford chamber of commerce is taking the initiative in protesting against the type of road to be laid on the provincial highway, and will request all municipalities from Hamilton to Windsor, or near the highway, to co-operate in opposing the laying of a bituminous macadam road. The request for co-operation in the matter will be sent to the municipalities to urge the government to build the road of concrete as originally intended.

Chatham, Ont.—Tenders will be received until September 27th, by W. M. Abraham, R.R. No. 1, Chatham, for construction of 5,000 sq. ft. of sidewalks at Louisville, township of Chatham. Plans, etc., at office of W. G. McGeorge, engineer, Chatham.

Edmonton, Alta.—City council proposes to construct plank sidewalks on 93rd, 95th, 103rd, 114th, 115th and 116th Streets, and on 103rd, 103A and 104th Avenues. C. E. Cox, city clerk.

Enniskillen Tp., Ont.—Tenders will be received by Angus Stonehouse and Andrew Elliott, Commissioners, up to 6 p.m. on Wednesday, October 15th, 1919, for the repair of the McCrae drain. Plans and specifications may be seen at the office of Geo. V. Wyast, Petrolea, township clerk.

Ferguson Falls, Ont.—The new steel-concrete bridge over the Mississippi river has been completed and is now open for traffic. Bridge is 260 ft. long with five concrete piers and approaches. Superstructure is of steel with concrete roadway. Cost of steelwork, $14,000; total cost, including partial removal of old wooden structure, $20,612.60.

Fort William, Ont.—Contract has been awarded to the National Paving Co. for construction of pavement on Vickers St. at the C.N. Ry. station. Contract price, $4.65 per sq. yd. Curbing to Peter Bell, contract price, $1.70 per lin. ft.

Galt, Ont.—City council proposes to construct asphaltic concrete pavement on Queen St. W., from West Main St. to Blair Rd., and a bituminous macadam pavement westward from the railway tracks to Blair Rd.

Hamilton, Ont.—County council granted permission to the village of Freelton for construction of sidewalk on east side of Brock Rd. to the 9th concession.

Hamilton, Ont.—The property committee has recommended to the board of control that work proceed immediately on construction of concrete platforms and roads required for the new market shelters. Estimated cost of concrete work, $10,000.

Hartney, Man.—Tenders will be received until 10 a.m., October 17th, by the council of Cameron municipality for construction of a wooden pile bridge across the Souris river, between sections 6 and 7 in 6-23. T. B. Woodhull, secretary-treasurer.

Hatley, Que.—Tenders will be received by the council of the village of Hatley, until 1 p.m., October 3rd, for construction of roadbed and concrete bridge at Woodman brook on the Massawippi Rd. H. B. Whitcomb, secretary-treasurer.

Montreal, Que.—The Automobile Club of Canada in co-operation with local boards of trade will urge the Dominion government to complete construction of the Laprairie dyke and roadway.

Mt. Lehman, B.C.—Council will undertake temporary repairs to the main roads this fall. R. Owens, Matsqui.

New Glasgow, N.S.—Ratepayers have authorized issue of bonds providing for extension of Archimedes St., $6,800; pavement on Glasgow St., between Victoria St. and Imperial Oil, Ltd., $4,500; sidewalks on Forbes St., s.s.; McLean St., both sides; Albert St., both sides; East River Rd., e.s.; Washington St., w.s.; Abercrombie Rd., both sides; Willow Ave., s.s.; Maple Ave., both sides; North Provost St., e.s. Estimated cost of sidewalks, $17,000.

Newmarket, Ont.—Contract has been awarded by town council, to Sheardown & Bone, for construction of concrete bridge opposite lot No. 7, concession 4. Contract price, $3,200.

Oil Springs, Ont.—Tenders will be received by D. P. Sisk, village clerk, Oil Springs, up till 8 p.m. on Tuesday, September 30th, 1919, for the construction of a granolithic sidewalk. For particulars apply to Ellwood Mott.

Orillia, Ont.—Contract has been awarded by the county council to Curran and Clement, for construction of a 20 ft. concrete pavement on the Atherley Rd. Contract price, $1.10 per sq. yd., cement to be provided by county. County engineer Campbell.

Orillia, Ont.—Contract has been awarded by the G.T. Ry. for construction of bitulithic pavements in the station yard to the Warren Bituminous Paving Co., Toronto.

Ottawa, Ont.—At a recent meeting the Carleton County Council gave the first reading to a by-law calling for the raising of $75,000 for a new 400-foot bridge across the Mississippi River, about two miles from Galetta, in Fitzroy township.

Preston, Ont.—Preston Parks Commission will construct a two-mile automobile drive and bridal path in Speed Park. Other improvements include tearing down of the old hockey rink and erection of a soldiers' memorial gate. Total estimated cost, $25,000.

Regina, Sask.—The Crown Paving Co., who recently secured the contract to resurface Dewdney St., east of Albert St., have commenced work. Contract price, $21,000.

Scarboro Township, Ont.—Township council contemplate opening the government road running from stop 22, Kingston, to the side line between lot Nos. 26 and 27.

Spencerville, Ont.—Construction of roadbed on the Ottawa-Prescott highway, between Kemptville and Prescott, has commenced. It is expected that the abutments for the new highway bridge over the Nation river will be completed this year.

St. John, N.B.—G. N. Hatfield, city engineer, is preparing a program of street paving to cover a period of 4 years. Estimated cost, $1,000,000.

Toronto, Ont.—City council has passed a by-law providing for pavements on sections of St. Clair Ave.

Toronto, Ont.—The Toronto civic guild has prepared a plan for a proposed widening of Bloor St., east of Yonge St. to Sherbourne St.

Toronto, Ont.—The work of raising the grade on Weston St., at Mount Pleasant Rd. has been completed for 400 yds. along the north side, and has been started for the same distance on the other side.

Toronto, Ont.—Plans are being considered by the provincial secretary and property commissioner Chisholm, city of Toronto, construction of a road through the jail grounds at Gerrard St. and Broadview Ave.

TENDERS FOR SUPPLIES

Tenders will be received by registered post only, addressed to the Chairman, Board of Control, City Hall, Toronto, up to 12 o'clock noon on Tuesday, October 14th, 1919, for the supply and delivery of:—

Tender No. 41—Trainmen's Uniform Overcoats.
Tender No. 49—Revolving Cantilever Crane.
Tender No. 50—Canopies for Subways.
Tender No. 52—Two Motor Trucks.
Tender No. 53—Concrete Mixer.

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. Tenderers must comply strictly with conditions of city by-law as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH (Mayor),
Chairman, Board of Control.
356

TENDERS WANTED

County of Huron, Ont.

Tenders will be received until October 11th, 1919, for the construction of the Kirk and J. B. Young Drains in the Township of West Wawanosh, County of Huron, Ontario. Kirk Drain 11,830 cu. yds. open work, 845 cu. yds. covered work. J. B. Young Drain, 15,300 cu. yds. open work, 272 cu. yds. covered work.

Plans may be seen at the office of John Roger Mitchell or at the office of the Township Clerk, Lucknow.

A marked check for 10 per cent. of tender must accompany each tender. The lowest or any tender not necessarily accepted.

W. A. WILSON, Clerk,
357 Lucknow P.O., Huron County, Ont.

Toronto, Ont.—City council will consider plans for extension and widening of Leader Lane, University Ave., south to Union Station, widening of York St., and construction of a new street between York and Bay Sts., southerly to Front St.

Toronto, Ont.—Plans have been prepared by the Railway and Bridge Section of the Toronto Works Department for a wooden trestle on St. Clair Ave. East. Tenders will soon be called for the construction of this trestle with the idea of extending the St. Clair Ave. civic car line eastward across Yonge St., thence northward through the Mount Pleasant Cemetery grounds and along Mount Pleasant Rd. to the city limits.

Toronto, Ont.—Tenders will be received up to noon, September 30th, for the construction of the following works: Asphalt Pavements—Annette St., from Keele St. to High Park Ave.; Annette St., from High Park Ave. to Fairview Ave. (except the intersections of Quebec, Clendenan and Evelyn Aves.); Fernwood Park Ave., from Fir Ave. to Hazel Ave.; Fernwood Park Ave., n.s. Fir Ave. to 306 ft. south; Front St., from John St. to w.s.l. Spadina Ave.; McLean Ave., from Queen St. to south end; Middleton St., from Sheridan Ave. to Brock Ave.; Kenilworth Ave., from Queen St. to 200 ft. north; Kenilworth Ave., from 200 ft. n. of Queen St. to 1,228 ft. s. Kingston Rd.; Logan Ave., from G.T.R. tracks to Gerrard St. Bitulithic Pavements—Northcliffe Blvd., from Regal Rd. to St. Clair Ave. (except intersection Lauder Ave.); Rosemount Ave., from Glenholme Aye. to Northcliffe Blvd.; Springmount Ave., from Oakwood Ave. to n.l. lot No. 30, plan M-312. Brick Block Pavement—Waverley Rd., from 1,300 ft. n. of Queen St. to Kingston Rd. Concrete Pavement—Belsize Drive, from Yonge St. to Mt. Pleasant Rd. (except the intersection of Wilfred Ave.); Manor Rd., from Yonge St. to e.s.l. Oswald Cres.; Sheldrake Blvd., from Yonge St. to Sheldrake Ave.; Sheldrake Ave., from n.s.l. Sheldrake Blvd. produced to Beulah St. running south. Grading—Benson Ave., from Hendrick Ave. to Ossington Ave. Concrete Curbings—Annette St., s.s., from Keele St. to Aziel St.; Elmsley Place., e.s., from St. Joseph St. to 350 ft. n. and w.; Elmsley Place, w.s., from St. Joseph St. to 380 ft. n. and e.; Front St., n.s., from John St. to Spadina Ave.; Middleton St., n.s., from Sheridan Ave. to Brock Ave.; Waverley Rd., w.s., from 1,488 ft. 6 in. n. of Queen St. to 165 ft. 8 in. farther north; Waverley Rd., e.s., from 1,501 ft. n. of Queen St. to 171 ft. farther north. Concrete Sidewalks—Atlantic Ave., w.s., from King St. to 1,190 ft. south; Bellefair Ave., w.s., from 14 ft. 6 in. s. of n.s. Juniper Ave. to 349 ft. 6 in. south; Cherokee Ave., from Lake Shore Ave. to Iroquois Ave.; Eastern Ave., s.s., from Morley Ave. to 139 ft. 2 in. west; Erie Terrace, e.s., from Queen St. to Gerrard St.; Kenilworth Ave., e.s., from Queen St. to 1,421 ft. north; Kenilworth Ave., w.s., from 1,228 ft. s. of Kingston Rd. to 593 ft. farther south; King St., s.s., from 92 ft. w. of Dowling Ave. to 509 ft. 6 in. farther west; McGregor Ave., s.s., from Durie St. to Runnymede Rd.; McLean Ave., e.s., from Queen St. to 1,128 ft. south; Nothcliffe Blvd., w.s., from Regal Rd. to St. Clair Ave.; Ranleigh Ave., s.s., from 892 ft. e. of Yonge St. to Ronan Ave.; Silver Ave., s.s., from Golden Ave. to 307 ft. 4 in. east. T. L. Church, chairman, Board of Control.

Treherne, Man.—Tenders will be received by R. J. Mills, secretary-treasurer, Municipality of South Norfolk, Treherne, Man., up to noon on September 29th for grading. Approximate quantity, 9,000 cubic yards. Specifications may be obtained from the office of the Good Roads Board, Parliament Buildings, Winnipeg, or from the secretary-treasurer.

Victoria, B.C.—Tenders will be received until 12 o'clock noon, October 15th, by the department of railways, for supply and erection of steel for superstructure of Deep Creek viaduct on the P.G.E. Ry. Plans, etc., office of P.G.E. Ry., Vancouver block, Vancouver, and at the department, Victoria. A. F. Proctor, chief engineer.

Winnipeg, Man.—Residents of River St. have asked for removal of car tracks and construction of an asphalt pavement. Estimated cost, $40,000. J. Cockburn, alderman.

Tarvia

Preserves Roads
Prevents Dust~

Queenston & Grimsby Stone Road, Lincoln County, Ont. Tarvia-filled macadam in 1916. Finished with "Tarvia-B" in 1917.

A view of Jordan Hill section of the Queenston & Grimsby Stone Road in Lincoln County, Ont. Tarvia-filled macadam in 1916. This road was treated in 1917 with "Tarvia-B."

Auto-Tank Sprayer distributing Tarvia

County of Lincoln (Ont.) adopts Tarvia for all main highways—

The following letter from Mr. Lewis H. Collard tells the story of the experience of the County of Lincoln, Ont., with Tarvia roads. It proves again that Tarvia solves the good road problem satisfactorily and economically, and that Tarvia highways will stand up under the heaviest kind of traffic.

Mr. Collard writes :

" I feel that if I did not give you an unsolicited testimonial of my experience with your Tarvia products, I would not be doing my duty to my fellow municipal officers in the Dominion of Canada, who may have under their consideration the building of some more permanent highways than the old water-bound macadam type.

The County of Lincoln two years ago built about two miles of Tarvia road on its main highway from the village of Jordan, running west, better known as the Queenston & Grimsby stone road, a road which carries the traffic from Canada to the Niagara Frontier and from the United States to Hamilton, Toronto, and farther east, and therefore is one of the heaviest travelled roads in the Province of Ontario, both in tourist and local traffic, having as high as one thousand automobiles and trucks passing over it in a day, and I can only say, after two years of this kind of traffic, the road is in first class condition to-day, and has pleased the County of Lincoln so much that they intend to build their main highways in the County Road system of the same type."

(Signed) LEWIS H. COLLARD,
Chairman, Lincoln County Roads

Nothing more need be said, except to remind you again that no matter what your road problem may be—whether you require a road binder, a dust preventive, a road preserver, or a patching material—there is a grade of Tarvia for the purpose.

Write for further information and illustrated booklets

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S. VANCOUVER

Welland, Ont.—The highways department, Ontario, has finally approved construction of concrete pavement in the village of Ridgeway. Contract for this work was awarded, early in July, to Begy & Co., St. Catharines, at $29,500. Albert Nelson, chairman, good roads committee.

West Vancouver, B.C.—Contract has been awarded by the department of works to Cotton Co., Ltd., for re-surfacing Marine Drive. Contract price, $2,650.

Windsor, Ont.—A by-law to provide $30,000 for construction of sidewalks in various parts of the city has been endorsed by the ratepayers.

Winnipeg, Man.—The transportation committee of the city council has recommended the repaving of River Ave. City engineer, W. P. Brereton.

Winnipeg, Man.—Bonds will be issued by the provincial treasurer for construction of additional good roads. Bond issue, $250,000. Hon. E. Brown, treasurer.

Winnipeg, Man.—Canadian National Railways awarded contract for extension to power house, Winnipeg, to H. Edwards, Winnipeg, and contract for section houses, C.G.R. line, to J. H. Simmons, Winnipeg.

WATER SEWAGE AND REFUSE

Belleville, Ont.—An outlet for the large drain being constructed on West Moira St., has been secured, by purchase, from the Pringle estate.

Belleville, Ont.—Council contemplates construction of a sanitary sewer on Commercial St., from Dundas St. to West Bridge. Estimated cost, $6,339. J. G. Mill, city engineer.

Galt, Ont.—City council will construct sewers on Huron and James Sts., and on Myrtle Ave., with an outlet through Dickson Park.

Halifax, N.S.—Contract has been awarded by the city council for completion of construction of sewer and water services on Agricola St., abandoned by W. F. Lecuyer, to Dow and Kaiser. Contract price, $1,867. Rejected tenders from Robertson and Hanrally, $2,480; Cook and Dembrack, $2,755; J. A. Chousse, $3,425. F. W. W. Doane, city engineer.

Hamilton, Ont.—The lower end of the Clark Ave. sewer will be raised and relayed to Ferrie St. New sewers will be constructed on Ferrie St. from Clark Ave. to Cathcart St. E. R. Gray, city engineer.

Lucknow, Ont.—Tenders will be received until October 11th, by the council of township of West Wawanosh, county of Huron, for construction of the Kirk drain, estimated excavation, 12,675 cu. yds., and the J .B. Young drain, estimated excavation, 15,572 cu. yds. W. A. Wilson, clerk.

New Liskeard, Ont.—Council has authorized construction of sewer and water mains from Whitewood Ave. to R. G. Howie's property.

Regina, Sask.—City council will commence drilling at Boggy Creek to obtain increased supply of water.

Smiths' Falls, Ont.—Town council will construct sewers on Thomas St. and on Robina Ave. from Smiths' Falls Ave. to Chambers St.; and on King St. from Robina Ave. to Smiths' Falls Ave.

Toronto, Ont.—Tenders will be received until noon, September 30th by the board of control, for excavating, laying and jointing of 24 in. water pipes, valves and special castings on Victor Ave. Plans, etc., at water main extension section, city hall. T. L. Church, chairman.

Winnipeg, Man.—The concrete pipe line and intake under construction by the Greater Winnipeg Water District will be entirely completed by November 1st.

York Township, Ont.—Contracts have been awarded by township council for construction of water mains as follows: To Orsiny Construction Co., Pinewood Ave., etc., $2,-312.50. Rejected tenders from Angelo Cavotti, $2,515, and Peter Isles, $3,479.50. To Peter Isles, West Morningside Ave., etc., contract price, $4,240. Rejected tenders from Orsiny Construction Co., $4,724.50, and Angelo Cavotti, $4,-708. Frank Barber, engineer.

York Township, Ont.—Township council has received approval of railway board for construction of 12 in. trunk water mains on Bathurst St., Connaught and Lonsdale Aves.

York Tp., Ont.—Tenders will be received until noon, October 4th, by township council for construction of 6-in. cast-iron water mains in the following streets: (1) Belvidere Ave., 680 lin. ft. (2) Forest Hill Rd., Huron St., Burton Rd., Claremount and Westmount St., 6,097 lin. ft. (3) Sunnybrae Cres., Denarda St., 1,535 lin. ft. (4) Corbett Ave. and Mould Ave., 2,009 lin. ft.; 12-in. cast-iron water mains on (5) Bathurst St., Lonsdale west and Lonsdale east, 3,490 lin. ft. Frank Barber, 40 Jarvis St., Toronto, engineer.

LIGHT, HEAT AND POWER

Halifax, N.S.—The Nova Scotia water powers commission will obtain reports regarding the Indian and the North East river with the view of developing the water powers. E. H. Armstrong, chairman.

Hamilton, Ont.—The Parks Board accepted the tender of R. Fitzsimmons for installing boilers at the greenhouses at Gage Park for $1,450. The only other tender was from W. J. Walsh for $1,596.

Highland Creek, Ont.—The Iroquois Gravel Co. will receive power from the Hydro-Electric system. It is expected that the surrounding district will obtain a domestic lighting system at the same time.

Islington, Ont.—Etobicoke council has requested the Hydro-Electric Commission to construct street lighting system on Oliver Ave., Humber Bay district.

Mt. Lehman, B.C.—Council will ask the Western Canada Power Co. to supply electric power to the farmers in the Fraser valley.

Nelson, B.C.—The Mankin Lumber and Pole Co. will construct a flume line, 3 mls. long, from Hall creek to the mill site.

Sydney, N.S.—The Nova Scotia Steel and Coal Co. may electrify its present railroad system.

Truro, N.S.—Town council decided to enlarge electric lighting plant. A 150-300 k.w. turbine generator and a 400 h.p. boiler will be installed. Estimated cost, $50,000. J. G. W. Campbell, town engineer.

Winnipeg, Man.—Bonds will be issued by the provincial treasurer for construction of the first section of the provincial hydro system. Bond issue, $250,000. Hon. E. Brown, treasurer.

York Township, Ont.—Residents of Pendeen Ave. and of Bexley Cres. have petitioned council to construct extensions of hydro lighting system.

RAILWAYS

Charlottetown, P.E.I.—The first standard gauge train on the P.E.I. Ry. was run recently, from Borden to Summerside and Charlottetown.

London, Ont.—City council contemplates purchase of the London Street Railway system. By-law will probably be placed before the ratepayers next January. H. A. Brazier, city engineer.

Quebec, Que.—A spur line railway will soon be constructed from the main line to the new developments in the iron ore fields, province of Quebec. M. J. O'Brien and S. N. Parent, Quebec.

Toronto, Ont.—The Hydro-Electric Power Commission will construct the hydro-radial from Toronto to Pickering, as soon as the township of Scarboro guarantees bonds to the extent of $900,000, and the township of Pickering bonds to the extent of $300,000. Deputy reeve Crocker, Birchcliff.

Toronto, Ont.—The proposed entrance for the Toronto-Pickering hydro-radial would cost $4,328,665. Plans have been prepared by the Hydro-Electric Power Commission, and a by-law will probably be placed before the ratepayers January 1st. F. C. Gaby, chief hydro engineer.

Windsor, Ont.—The city council has notified the Sandwich, Windsor and Amherstburg Street Railway Co. of intention to purchase upon expiration of the franchise in 1922. It is expected that the Ontario Hydro-Electric Power Commission will buy and control this railway and operate in conjunction with hydro-radials to St. Thomas, Brantford, Hamilton and Toronto. E. B. Winters, mayor.

Winnipeg, Man.—The Manitoba government has decided to build 72 mls. of railway into the mining district north of Le Pas this winter, if the Dominion government will not. Hon. Edward Brown.

FACTORIES AND LARGE BUILDINGS

Belleville, Ont.—A modern dairy building will be erected on the Cumming estate on Coleman St. C. Whelan, Belleville.

Brandon, Man.—Tenders will soon be called for construction of the proposed hospital. Plans, which are practically completed, call for a capacity of 200 beds.

Canso, N.S.—A cottage hospital will be erected and equipped as a soldiers' memorial. Capacity, 10 to 12 beds.

Ford City, Ont.—Contract has been awarded by school board for construction of new separate school to Wells and Gray. Contract price, $140,000. J. C. Pennington, architect.

Fort William, Ont.—A grant of $112,000 has been made by the provincial government toward the cost of construction of a technical school to be built in Fort William.

Fredericton, N.B.—A committee has been formed to prepare plans and estimates of cost of constructing and equipping a building in connection with the University of New Brunswick, where technical work may be carried on for benefit of returned soldiers.

Galt, Ont.—Contract for the construction of the one-story, stone bank building for the Bank of Toronto, has been awarded to the Dickie Construction Co., Ltd., Toronto.

Guelph, Ont.—The Chamber of Commerce have secured a site on Cambridge St. for the erection of a skating rink, which will likely be built this fall at a cost of about $50,000.

Hamilton, Ont.—At a recent meeting of the Parks Board, chairman Alfred Wright presented plans for a stadium and athletic field which it is proposed to build in the east end of the city. The plans call for an expenditure of $100,000.

Hamilton, Ont.—Contract has been awarded for construction of one 4-story reinforced concrete factory, 56 by 146 ft.; 3 buildings, 63 by 362 ft., 123 by 144 ft., and 81 by 62 ft.; 1 office building, 62 by 45 ft., as follows: W. H. Yates, Hamilton, Ont., general contract; Hamilton Bridge Co., Hamilton, steel; Trussed Concrete Steel Co., Toronto, reinforcing steel; J. B. Ormsby Co., Toronto, steel sash. W. J. Westaway Co., Hamilton, architect and engineers for the Porrits and Spencer Paper Manufacturing Co. A. Sande, resident engineer.

Kitchener, Ont.—A. B. Pollock Manufacturing Co. will build an extension to their plant.

Kitchener, Ont.—The Lang Tanning Co. will erect two warehouses. Estimated cost, $24,000.

Kitchener, Ont.—Contract has been awarded by the Ames-Holden Tire Co. to Dunker Bros., for construction of a two-story felt factory in Hall's lane.

Kitchener, Ont.—Negotiations are under way between W. N. McEachern and Sons, Ltd., house builders, and a number of manufacturers in this city to have from twenty to thirty houses built this fall in each of the five wards of the city.

Medicine Hat, Alta.—Contract has been awarded for construction of courthouse as follows: Steelwork, Dominion Bridge Co., Ltd., Winnipeg; steel sash, Trussed Concrete Steel Co., Walkerville, Ont. Total cost, $132,000.

Midland, Ont.—The Midland Whitewear and Costume Co. contemplates additions to factory and installation of new machinery. J. N. Graham, manager.

Montreal, P.Q.—It has been announced that the Canadian Pacific Railway Co. intend to rebuild the Place Viger Hotel in the near future into a modern hotel of ten storeys.

Montreal, P.Q.—Plans have been prepared by Chas. M. Mitchell, architect, Montreal, for the erection of an arena on Mount Royal Ave. for the National Sporting Club, Ltd., now in process of incorporation. The plans also call for the erection of eight stores.

Peterborough, Ont.—Contracts for construction of South Central school to be known henceforth as Memorial school, have been awarded by the board of education as follows: General contract to Graham and Hayes, $159,963; heating and ventilating, to R. C. Sturgeon and Co., $32,145; plumbing, fixtures and drainage to G. Brenton, $13,000; electric wiring and conduits to Miller, Powell and Watson, $2,747. Contracts awarded total $207,855. Additional costs for grading, walks, water connections, equipment, etc., will increase total cost to $240,000.

Purple Springs, Alta.—Tenders will be received by the Board of Trustees of School District No. 3761 of Skiff at the office of O. J. Graham, secretary-treasurer, Purple Springs, Alta., up to noon, September 30th, for the erection of a frame school building. Plans and specifications may be obtained from the secretary-treasurer.

Regina, Sask.—Contract has been awarded for construction of round house addition for the G.T.P. Ry., to Carter, Halls and Aldinger. Contract price, $15,000.

Regina, Sask.—The congregation of the Fourteenth Ave. Methodist church contemplates construction of a new church building. Rev. P. Iveson Thacker.

Retlaw, Alta.—Tenders will be received by the Board of Trustees of School District No. 3810, Retlaw, at the office of M. Watterberg, secretary-treasurer, up to noon, September 30th, 1919, for the erection of a frame school building. Plans and specifications may be obtained from the secretary-treasurer.

Sarnia, Ont.—The International Bushings Co., Ltd., will erect a plant in the near future. C. E. Calvert, Toronto, president.

Sedgewick, Alta.—Contract for plumbing, heating and ventilating the new eight-room school has been awarded to Ross Bros. Plumbing and Heating Co., Ltd., Edmonton.

Sherbrooke, Que.—In order to house the increased staff of workers which will be required when the Connecticut Cotton Mills doubles the size of the present plant, the Sherbrooke Housing Co. has been proposed. A model housing scheme will be developed in the western section of the city.

South Vancouver, B.C.—The G.W.V.A. have appointed a committee to report on project of constructing houses under day labor plan.

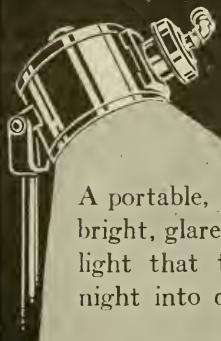
St. John, N.B.—Tenders will be received until 12 o'clock noon, October 6th, by the Department of Public Works, Ottawa, for construction of a grain conveyor (the equipment not being included) in St. John harbor, West St. John, N.B. Plans, etc., office of engineer-in-charge, St. John; district engineer, Shaughnessy building, Montreal, Que., and Equity building Toronto. R. C. Desrochers, secretary.

St. Thomas, Ont.—The St. Thomas Cabinets, Ltd., will establish a factory to manufacture gramaphone cabinets.

St. Thomas, Ont.—Contract has been awarded by the board of education to A. E. Ponsford for construction of an addition to Myrtle St. school. Contract price, $50,830; heating to Hamilton and Scott, $8,393; plumbing to J. A. McKenzie, $2,152.18; wiring to Roberts and Sandham, $325; heat regulator to Johnson Co., Toronto, $1,059; total cost, $62,759.68. Rejected tender, Sanders and Bell, $66,881.

Three Rivers, Que.—The International Paper Co., Ltd., is erecting a plant, consisting of eighteen buildings. Total estimated cost, $6,000,000.

Toronto, Ont.—Construction of the new electrical building for the University of Toronto has again been resumed.



ELECTRIC DAYLIGHT

WITH THE

Northern Electric

DAVIS

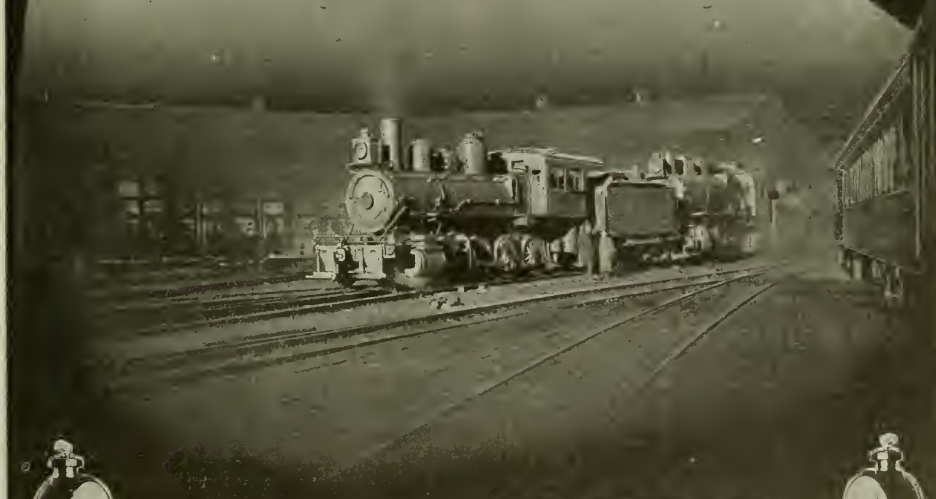
FLOOD LAMP

A portable, bright, glareless light that turns night into day.

It can be diffused over large areas or projected in a solid beam.

The light that lights Niagara

These Flood Lamps are ideal for lighting railroad terminals—freight yards—round houses—transfer yards and platforms—wrecking equipment – wherever working light is needed.



They can be used anywhere—no arc lamp trimming—no moving parts—no permanent wiring.
Write for our folder and tell us your lighting problems.

HALIFAX TORONTO REGINA VANCOUVER

Toronto, Ont.—City council will erect temporary bleachers in Riverdale and Willowvale Parks to provide accommodation for winter sports. Estimated cost, $2,400.

Toronto, Ont.—Stadium plans, recently prepared by the city architects department, include grandstand with dressing rooms, $47,000; grandstand without dressing rooms, $42,000; two bleachers, each $7,300; wooden fence, $5,450; and four ticket offices, $1,000. Total cost, exclusive of track, $110,050. Seating capacity, 10,000.

Toronto, Ont.—The board of directors, Canadian National Exhibition, Toronto, is considering elaborate plans for proposed extensions, including enlargement of transportation building, art gallery and grandstand and new buildings, arena, cattle barns, machinery hall, two large lavatories, large central restaurant, hospital, women's rest at east end of grounds, live stock hospital, education and music building, building for lost children and a dog building. John G. Kent, manager.

Vancouver, B.C.—By-laws have been prepared providing for alterations and additions to schools. Estimated cost, $181,500. Wm. McQueen, city clerk.

Vancouver, B.C.—The Gregory Tire and Rubber Co., Ltd., are preparing plans for construction of a reinforced concrete tire factory to be 200 ft. long and 80 ft. wide.

Walkerville, Ont.—An additional grant of $200,000 has been received by the Walkerville Housing Commission.

Waterloo, Ont.—Contract has been awarded by the park board for construction of a comfort station to Louis Holle.

Welland, Ont.—Plans have been completed and construction will soon commence on the new three-story building for the Bell Telephone Co.

Windsor, Ont.—The United Hotels Co. will construct a large modern hotel. Estimated cost, $1,000,000. F. L. Dudley, president.

Windsor, Ont.—As a result of the passing of the by-law, granting for 10 years a fixed assessment of $10,000, the Fisher Closed Body Co. will construct a plant to manufacture auto bodies.

Winnipeg, Man.—The Manitoba Government Telephone Commission will construct a large garage, fireproof construction. Estimated cost, $51,200. J. H. Russell, architect.

Winnipeg, Man.—The Tavani Electric Steel Co., Belleville, Ont., are contemplating construction of a steel and iron foundry in Winnipeg. Estimated cost, $5,000,000.

Woodstock, N.B.—Plans are in contemplation for the erection of several new buildings at the Woodstock Fair grounds.

MISCELLANEOUS

Amhertsburg, Ont.—Tenders will soon be called for channel construction in the lower Detroit river.

Glace Bay, N.S.—Messrs. Green and Smith, representing English capital, contemplate construction of a shipyard as well as the $5,000,000 drydock.

Hamilton, Ont.—Parks Board awarded contract for the erection of a new wharf at Wabasso Park to the Canadian Engineering and Construction Co. for $34,400. Other tenders received as follows: McAllister and Taylor, $43,000, and W. T. Brennan and Co., $43,317.

Lethbridge, Alta.—Farmers, north of Lethbridge, representing owners of 208,000 acres, have endorsed the erection of the Lethbridge northern irrigation project. Vote was taken under terms of the Alberta Irrigation District Act.

Lethbridge, Alta.—By order-in-council, the federal government has provided that all the unappropriated waters of the St. Mary, Milk, Belly, Old Man and Waterton rivers and their tributaries in Alberta shall be reserved for purposes of irrigation.

London, Ont.—City engineer Brazier proposes to establish a plant for manufacture of cement tile to be used in storm sewer construction.

Montreal, Que.—The administrative commission will be urged by the city council to enlarge the St. Dennis St. tunnel. Alderman Carmel.

Moose Jaw, Sask.—Public school board contemplates construction of an enclosed fire-escape for use at Alexandra School. Estimated cost, $4,000. G. D. Mackie, city engineer.

New Glasgow, N.S.—Ratepayers have authorized issue of bonds to provide for purchase of equipment for street purposes. Estimated cost, $7,500.

Ogdensburg, Ont.—Contract has been awarded by the department of public works, Ottawa, to the Daly Dredging Co., for dredging Ogdensburg harbor. Contract price, $65,000. Estimated excavation, 360,000 cu. ft. R. C. Desrochers, secretary.

Peterboro, Ont.—Contract has been awarded by department of railways and canals, Ottawa, for rebuilding north pier at Farran's Point, to McGuire and Cameron.

Prince Albert, Sask.—Excavation for the new east cell wing for the penitentiary has been started. R. F. Uniacke, structural engineer, Dominion government penitentiaries.

Regina, Sask.—Tenders will be received until 4.30 p.m., September 29th, by the highway department, province of Saskatchewan, for excavation for the following reservoirs: N.W. ¼ sect. 10-25-22, west of 3rd meridian, Snipe Lake post office; n.e. ¼ sect. 15-28-20, west of 3rd meridian, south of Brock; n.e. ¼ sect. 21-27-24 west of 3rd meridian, south of Fairmont. H. S. Carpenter, deputy minister.

Rimouski, Que.—Tenders will be received by the monument committee until October 30th for the erection of a soldiers' memorial monument. C. A. Couillard, secretary.

Saskatoon, Sask.—Contracts have been awarded by the School Board for installation of heating, ventilating and plumbing systems for the Mayfair School to Chas. D. Kirk Co., Winnipeg. Contract price, $50,310. Contract for metal work was awarded to A. L. Charlebois, Saskatoon. Contract price, $5,060.

St. Catharines, Ont.—Doheny, Quinlan and Robertson, contractors on section No. 3, Welland ship canal, have received orders from the department of railways and canals, Ottawa, that construction work on section No. 3 be closed indefinitely.

St. John, N.B.—Tenders will soon be called for supplying 10,000 lin. ft. granite curbing. G. N. Hatfield, city engineer.

Sydney Mines, N.S.—Nova Scotia Steel and Coal Co. contemplate construction of a new by-product plant, necessitating construction of an additional blast furnace. Estimated cost, $3,500,000.

Sydney, N.S.—The Dominion Iron and Steel Co. contemplate enlarging the capacity of the open hearth by addition of newer and larger furnaces, which will cost several million dollars.

Toronto, Ont.—New tenders will soon be called for construction of a steel crane for the city of Toronto. T. L. Church, chairman, board of control.

Toronto, Ont.—The projected St. Lawrence river development as outlined by Sir Adam Beck, include construction of dams at Morrisburg and at Long Sault.

Vancouver, B.C.—Dredging operations under the contract recently awarded to the Pacific Dredging Co. for the North Arm, Fraser River, have commenced. Yardage to be excavated, 1,000,000 cu. yds. Time of completion, March 6th, 1920.

Winnipeg, Man.—Bonds will be issued by the provincial treasurer for additional telephone construction. Bond issue, $250,000. Hon. E. Brown, treasurer.

Winnipeg, Man.—City council has instructed the works committee to examine thoroughly into the selection and preparation of a suitable site for an airdrome.

Winnipeg, Man.—Contracts have been awarded by the city council for supply of two 3.5-ton trucks for the city engineer's department to the Grace Motor Co. Contract price for two Sterling trucks, $11,500.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Operation of Drifting Sand Filters at Toronto

Average Reduction of 85.4% in Total Bacteria and of 94.8% in B. Coli During Year 1918—Chlorination Killed Practically all Remaining Bacteria—More Coagulant Needed in Summer Than in Winter—Water Undergoes Two Distinct Changes During Year

By NORMAN J. HOWARD

Bacteriologist-in-Charge, Filtration Plant Laboratory, Toronto

PURIFICATION of the water supply for the city of Toronto is effected by means of two systems, one being a slow sand and the other a mechanical of the drifting sand type. The water is drawn from Lake Ontario to the south of Toronto Island, two intakes being situated a little over 2,000 feet from the shore, submerged in about 60 and 80 feet of water, respectively. The slow sand system has given excellent results, but when an extension was found necessary in 1914, the city decided on mechanical filtration, the reasons given being difficulties in operation caused by a combination of occasional high turbidity and the low temperature in the winter months.

The object of this paper is to give, as briefly as possible, a description of the drifting sand system* and the results of the operation and purification effected during 1918. Throughout the paper the word "gallons" are Imperial gallons. The capacity of the plant is 60 million gallons in 24 hours, but a maximum rate of 72 million gallons daily must be maintained for a period of 10 hours. The rate of filtration is somewhat higher than is usual with mechanical plants, the rate being 150 million gallons per acre per day. Before describing the plant it would be well to state the two principles involved in its operation. They are the introduction of a coagulant without sedimentation and the necessity for there being a drifting as well as a stationary body of sand in the filter. These would seem to be the two differences between modern mechanical plants of the gravity type and the drifting sand filter.

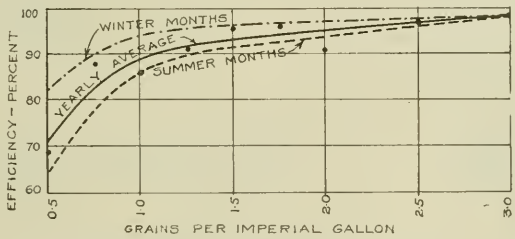

DIAGRAM OF BACTERIOLOGICAL EFFICIENCIES OF TORONTO'S DRIFTING SAND FILTRATION PLANT DURING YEAR 1918, SHOWING EFFECT OF INCREASING ALUM DOSE

In the Toronto plant the water flows by gravity from the intake into a suction well, where the coagulant is introduced, the water then being pumped directly to the filters.

The coagulation plant consists of a large storage bin in which is stored alumina sulphate used for coagulation purposes. Through a number of control doors the chemical is automatically fed to two dissolving channels, the density of which is kept from 12 to 14 degrees Baume (about 15% solution). The strong solution passes into a hydrometer chamber, where it is automatically diluted to the required strength. The hydrometer is poised in the solution between two valves, one discharging alum and the other water. Any vertical movement of the hydrometer opens one valve and closes the other. Thus the hydrometer tank is supplied with strong alum solution at the top, or water at the bottom, depending whether the hydrometer is up or down. The tank is made of concrete, whilst the hydrometer is steel, thickly covered with paraffin wax, and has a displacement of 6,000 lbs. of solution. It is weighted so as to just float in solutions of alum ranging between 4% and 10%. Owing to the differences in the density of alum and water, circulation is maintained, a 10% solution of alum being approximately 5% heavier than water. The heavier liquid coming in at the top immediately starts travelling downwards and meets the lighter liquid rising upwards. At the point of discharge a perfect mixture is obtained, it being impossible to detect stratification.

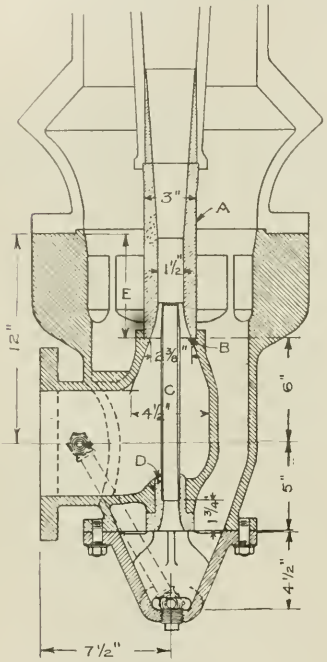
A beam with knife edges above the hydrometer, which is extremely sensitive, provides for permanent adjustment and also for altering the density of the solution. Along the beam is a scale of divisions graduated in 1/10th grains, so that by moving a weight the required strength of solution may be obtained. The solution of alum next discharges into an orifice chamber. A mechanical device regulates the discharge of solution, which is proportionate to the quantity of water being pumped, this being indicated by a Venturi meter which is directly connected with the measuring slot.

From the measuring tank the alum passes through lead pipe to the suction well and is pumped to the filters. The lift of water from the well to the filters is 32 ft. The pumping station includes three electrically driven pumps with a combined capacity of 100 million gallons and a lift of 32 ft. Besides these, there are a two-million gallon auxiliary pump with 32-ft. lift, two half-million gallon backwash tank pumps with 100-ft. lift, two one-million gallon drainage pumps with 20-ft. lift and two hydraulic-pressure pumps with a capacity of 8,640 gallons a day under 700 lbs. per square inch. The discharge of the main pumps is controlled automatically by the level of the water in the filter tanks, through pilot valves, operating hydraulic valves on the discharge of the pumps. There has also been installed a steam turbo-generator set, in case the electric power should fail.

The multiple filter unit system was adopted in Toronto, and consists of ten units, each having a nominal capacity of six million gallons. Each filter is made of steel, is 14 ft. high, 50 ft. in diameter, and is divided into thirty smaller units. These units are nested together in two rings of 18

*For photographs, plans, sectional drawings and further data regarding the construction and method of operation of this plant, the reader is referred to the following issues of *The Canadian Engineer*: October 24th, 1918, pp. 359-64; September 14th, 1916, pp. 203-10; November 25th, 1915, pp. 618-20; April 8th, 1915, pp. 433-8; April 23rd, 1914, pp. 639-41.

and 12 respectively. In the centre of the filter is a space 16⅔ ft. in diameter, in which is placed the raw water control balance. Each of the thirty units form a separate quadrilateral unit with sand extractors, sand washer and filtered-water-collecting system. For backwashing, an overflow channel 15 ins. wide and approximately 3 ft. deep is placed round the outer ring. At the bottom of each filter, partly embedded in the concrete, is a cast-iron collector pipe for the filtered water. Running out from the collector pipe are a series of 1½-in. wrought iron sheradized pipes, having ⅜-in. holes drilled on the underside, spaced about 6 ins. apart. These pipes have a cap on the outer end and the inner end is screwed into the cast-iron collector. On the top of the pipes is rounded gravel in three grades, varying from ¾ in. to ⅜16 in., to a depth of 10 ins., and above that is 9 ft. of sand.



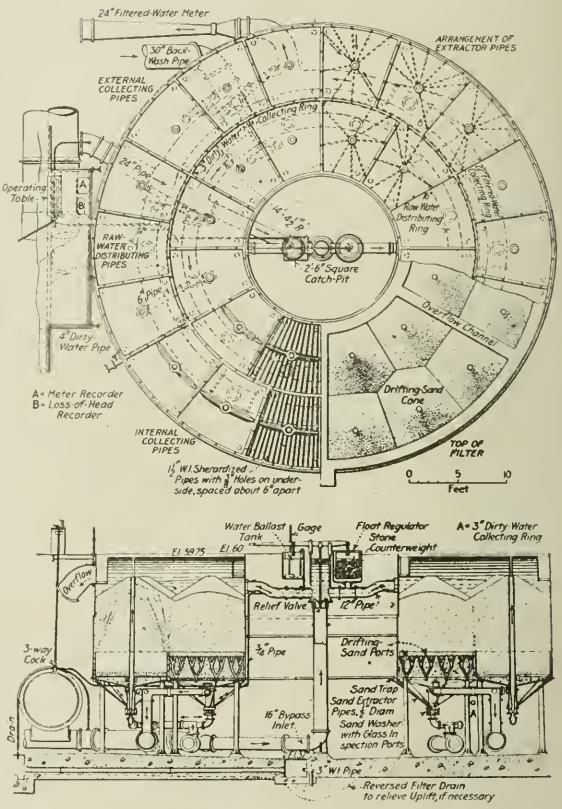
New Type of Sand-Washer Now in Use

(A) Throat made of drawn-steel tube, hardened right through; (B) thin rubber washer; (C) standard ¾-in. wrought iron pipe, hardened right through; (D) mild steel, hardened right through; (E) collar on throat to be set so that throat projects 6 1/16 ins. below flange face without compressing rubber ring at the top.

that the flow of sand from each extractor pipe can be observed. The sand washers are of cast iron. The throats are relined when occasion arises with wrought-iron pipe liners, specially hardened by a carbonizing process. The liners are in three steps and are 13½ ins. high.

Description of Process

The coagulant is introduced as the water goes direct to the filters, on the suction side of the pump. Owing to the operation of the drifting sand system, the sand contained in the filters resolves itself into two bodies—a stationary sand body supported by the gravel resting on the water collecting system and a drifting sand body lying between the surface of the stationary sand and the sides of the filter.



Details of Drifting Sand Filter at Various Horizontal and Vertical Planes

The total amount of sand in each filter is 600 cubic yards. No screens are used between the gravel and the sand. The sand has an average effective size of .375 mm., and a uniformity coefficient of from 1.6 to 2. Around each small unit is a system of slots and the drifting sand is withdrawn from the filter by means of extractor pipes, through which the sand flows to the bottom of the filter unit into a sand washer. At the sand washer the sand falls to the bottom through a current of raw water and is thus cleaned. It is picked up by the incoming raw water and carried back to the filter. The dirty water impurities or suspended matter pass upward and out at the top of the sand washer by an outlet suitably controlled. A water jet is provided to assist the flow of sand through the extractor pipes, and, below the point of discharge, a glass inspection port is provided, so

By causing the sand to drift across the path of the raw water, a large proportion of the impurities, including the aluminum hydrate and the bacteria that have been caught by the coagulant, are carried out along with a portion of the drifting sand. The stationary sand takes out the remaining impurities. The treated raw water enters the filter partly by a standpipe running through the centre of the unit, which passes through a sandwasher in the bottom, and delivers above the sand at the top of the pipe, and partly through a by-pass. Within the sandwasher the raw water pipe is constructed similar to that of the tube of a Venturi meter and the drifting sand after being collected and washed in the sandwasher, is inducted into the raw water at the throat of the Venturi tube. This sand passes up the stand-pipe with the raw water and is delivered at the top of the filter.

The drifting sand forms a volcano-like cone that continuously drifts away and is being replaced with the washed sand from the sand washer, leaving a round top body of stationary sand below, resting upon the filtered water collecting system. The final purification is dependent on this body of stationary sand. The rate of flow of water passing through the by-pass may be varied in such a way as to suit the conditions of the raw water. In times of high turbidity the speed of the drifting sand is accelerated by decreasing the flow of raw water through the by-pass and increasing the flow through the standpipe. When in operation the stationary body of sand is found to be hard and compact with a cone-shaped-like surface, which is hard to penetrate.

The drifting sand is quite buoyant and spongy and offers little resistance to penetration. In practice it is found that the slope of the drifting surface cone is a minimum of about 32 degs. and the slope on the surface of the cone forming the stationary sand is about 64 degs. The initial loss of head in the filters is 6 ft. and in the process of operation this gradually increases to 11 ft., when the filter is backwashed.

Length of run of filters ranges between one and seven days according to the physical condition of the raw water and the amount of alum applied. Backwashing is accomplished by reversing the flow of filtered water through the bottom of the filter. The water is obtained from an elevated tank having a capacity of 200,000 gals. and which, on account of its elevation, supplies a natural head of 40 lbs. Half the contents of the tank are passed through the filter at a gradually increasing rate, the first 100,000 gallons taking fifteen minutes, whilst the remaining quantity is passed through rapidly, the whole operation being completed in 20 minutes. The filter is then run to waste for 20 minutes, after which it is put into commission. The amount of dirty waste water passing through the sand washer is 2%, whilst an additional 1% to 2% is used for backwashing and waste purposes.

On a big plant, embracing an entirely new system, it was expected that numerous problems would be encountered, particularly when the plant was put in commission, but with few exceptions, the difficulties have, or will be shortly, overcome, and in no case can they be considered serious. In the early days, the biggest problem was to get a high grade sand. About two-thirds of the sand originally placed in the filters, amounting to over 4,000 cubic yards, had to be taken out and replaced at the expense of the contractors. At present the sand, whilst being satisfactory, is not quite uniform, having an effective size which varies between .35 and .4 mm. In the chemical house some inconvenience was caused by the corrosive action of the aluminum sulphate solution on the slotted trunk through which the solution is discharged into the raw water. The trunk was made of vanadium silver, which has since been replaced by one made of pure copper. Tests are at present being conducted in the laboratory on a composition consisting of copper 92 parts, lead 8 parts containing 1% of antimony.

The question of sand scour has been the most troublesome. When the filters were first put in commission, the cast-iron throats did not wear as long as was expected, and they were relined, first with extra heavy black iron pipe and finally with similar pipe carbonized. Porcelain was tried but was unsuitable and experiments with rubber are now under way. Most of the scour observed has been traced to a tail eddy which forms at the back of the sand nozzle by the water passing it. By using the modified sand washer the scour has been greatly reduced, and a number of new washers are being installed.

Some trouble was caused in one filter by too rapid backwashing, which resulted in the disturbance of the gravel. The filter was emptied and the gravel replaced by 4 ins. of 1-in. gravel, and 6 ins. of cemented gravel, in the proportion of 15 of gravel to 1 of cement. The gravel used was the material which passed through a screen having three meshes to the inch and was retained on a screen having five meshes to the inch. This has proved to be very satisfactory.

Table 2.—Average Number of Bacteria per cc. Growing on Standard Agar 24 Hours at 37-39 Degs. C., in the Raw, Filtered and Chlorinated Water, Together with Percentage Reduction

Month	Raw Water	Filtered Water	Mixed Mechanical and Slow Sand Water Chlorinated
January	42.2	3.3	1.2
February	7.4	1.2	1.0
March	43.0	3.2	1.6

The average amount of chlorine applied to the water was 0.2 parts per million.

Preliminary Experiments

Prior to the completion of the new drifting sand plant at Toronto, extensive laboratory experiments were carried out over a period of eighteen months, the object being to collect as much data as possible that would likely be of value when the plant was put in commission. After six months' observation it became evident that the water of Lake Ontario was going to be an extremely difficult water to treat mechanically; that is to say, the purification effected after coagulation, under apparently the same physical conditions, varied from time to time It was generally known that the quality of the water was governed by the meteorological conditions, which also controlled the temperature of the water.

In the summer months, when the water was warm and the wind from an unfavorable direction, there was invariably pollution. During the winter months the same unfavorable meteorological conditions produced a polluted water which showed a drop in temperature instead of an increase

such as usually occurred in the summer months. This was explained by off-shore currents, which carried the shore water out and at the same time met and mixed with the polluted water, which, in turn, was carried across the intake.

For the laboratory experiments two small rapid sand filters were built and sterilized. Raw water, treated with amounts of aluminum sulphate ranging between one-half and three grains per Imperial gallon, was then passed through under varying conditions at the rate of 120 million Imperial gallons per acre per day. The removal of bacteria in the effluents was pro rata to the quantity of alum applied, the results being strikingly uniform.

The time element was next studied, and the tests were made to determine what difference existed in the final purification between treated water after fifteen minutes' coagulation and after a period of three hours' coagulation and sedimentation. Little differences were noted, and the opinion was formed that the time element was not a factor in the resultant purification. Similar experiments were carried out in Ottawa with river water by Jos. Race, city bacteriologist, and he found that the results between periods of two and one-half minutes and two hours were substantially the same. Tests were duplicated in the warm weather, and it was then noticed that the purification figures obtained under similar physical conditions in the summer months, were considerably lower than were obtained in the winter months. In 1918, when enough units of the new plant had been completed so as to allow testing to be carried out on a large scale, many of the observations proved of great value, and showed that the coagulation trouble that had been anticipated, actually worked out similarly to what occurred in the laboratory in the small experimental filters. Amongst other observations made were the resulting purification after coagulation and filtration of:—

1. Lake Ontario water containing different degrees of turbidity.
2. Lake Ontario water free from pollution.
3. Lake Ontario water heavily polluted, winter conditions.
4. Lake Ontario water heavily polluted, summer conditions.
5. Temperature conditions of Lake Ontario water.

Turbidity did not help or hold up purification at any time of the year. The only effect was to cause an increased amount of alum to be applied at such times as was considered necessary for clarification purposes. Water free from pollution offered no difficulties. In the winter months a polluted water required at least one and one-half to two and one-half grains of alum in order to get a satisfactory effluent. During the summer months it was found necessary to apply at least two and one-half grains per Imperial gallon to a polluted water which often was free from turbidity. Water slightly polluted required about one grain per gallon. No satisfactory explanation of the varying conditions can be offered, although much experimental work has been carried out to determine what are the controlling influences.

No doubt temperature plays an important part, although it has been generally conceded that warm water aided coagulation. In Toronto the raw water appeared to coagulate slightly better in the summer months when the water temperature exceeded 50 degs. F., but the final purification effected was lower than in the winter period when the water temperature ranged between 33 and 46 degs. F.

The microscopic content showed great increase in summer months, as also did the total number of bacteria present; these, again, might be a contributory cause. The most logical idea is that the colloidal content of the water in some months was largely responsible for the conditions noted, and that a direct relationship existed between the microscopical, bacteriological and colloidal content. When the preliminary tests on the drifting sand experimental plant of one-half million gallon capacity were carried out in 1914 by Col. Nasmith and Capt. Adams, Humber Bay water was used (this was Lake Ontario water into which the Humber River flowed), and splendid efficiencies of over 98% were obtained on a test period of 36 consecutive days.

Purification Effected in 1918

With the object of showing the different degrees of purification effected in the two seasons of the year, the writer has grouped the results into two periods, the first being from December to May, and the second from June to November. The month of June produced a water that was easy to treat at all times, but for classification purposes was placed in the second period.

The appended tables show:—

1. Average amount of water filtered; amount of aluminum sulphate applied; turbidity in raw and filtered waters.
2. Average number of bacteria per cc. growing on standard agar in 24 hours' incubation at 37 degs. C. in:—

(a) Raw, filtered and chlorinated water, together with percentage reduction in filtered and chlorinated water, all results included.

(b) Same as above, exclusive of three results for reasons specified.

3. Same figures, classified under summer and winter groupings.

4. Tests for typical B. coli, 48 hours at 37-39 degs. C., showing number of days in raw, filtered and chlorinated water; indicated number of B. coli per 100 and 1 cc. in the raw and filtered water, together with the total percentage reduction.

(a) All results included.

(b) Exclusive of three results for reasons specified.

It has been previously mentioned that the raw water is subject to rapid changes. Frequently the water becomes heavily polluted after less than eight hours' change in the meteorological conditions. This makes the treatment exceedingly difficult, as occasionally a sudden pollution has occurred and an insufficient quantity of alum applied, with the result that the efficiency of the plant has been impaired.

Regarding the expression of results, inclusive and exclusive, no doubt some explanation should be offered for same. The results excluded are one in September and two in October, the reasons being that on two occasions abnormal pollutions occurred when the bacterial count in the raw

water was in the neighborhood of 15,000 per cc. and at the same time an insufficient quantity of coagulant (1.5 grains per gallon) was being applied. On the other occasion the alum was reduced too soon following a change in the direction of the wind. When chemical tests were made it was found that the water was still polluted, and consequently the alum was again increased. During the intervening period the sample was collected and proved to be unsatisfactory. As will be seen from the figures, the inclusion of these three results materially alters the average number of bacteria present, and also lowers the colon efficiency. The average number of bacteria per cc. growing on standard agar, 37-39 degs. C., was 369.5 in the raw and 53.4 in the filtered, inclusive of all results showing an average reduction of 85.4%. Excluding three records for reasons previously specified, the figure was 303.6 in the raw and 34.7 in the filtered, with an average reduction of 88.4%. The indicated number of B. coli per 100 and 1 cc. was 612 and 6.12 in the raw and 31.70 and .317 respectively in the filtered, with a total average reduction of 94.8%. If the three records before mentioned are excluded, the raw water would show 608 per 100 cc. and 6.08 per 1 cc., whilst the filtered water figure would be 22.0 per 100 cc. and 0.22 per 1 cc., with an average percentage reduction of 96.0%. The chlorinated water showed an average bacterial count of 1.72 per cc., whilst only two samples out of 1,900 samples examined showed the presence of B. coli in 1 cc. This gives a total removal of 99.9%.

A.—Indicated number of B. coli:—Raw water, 612 per 100cc.; filtered water, 31.70 per 100cc. Total reduction inclusive of all results:—Filtered water, 94.8%; chlorinated water, 99.9%.

B.—Indicated number of B. coli:—Raw water, 608 per 100cc.; filtered water, 22 per 100cc. Total reduction exclusive of three results for reasons specified, 96%.

Particular attention has been given to the clarification of the water, and it would be well to point out that the turbidity figures given are only those actually occurring at 9 a.m. daily. During the month of April, the figure in the raw water ran up as high as 550 parts per million, and the maximum figure recorded in the table as occurring in the filtered water followed this high period of turbidity. The raw water figure given in the table as 160, was the degree of turbidity actually present in the raw water half an hour previous to the collection of the filtered water sample, this being the estimated time for the water to pass through the filter from the time the coagulant was first added. It would seem to be scientifically incorrect to give only one set of figures, as a wrong impression might easily be formed.

The original specifications called for certain efficiencies being obtained on an average amount of one grain per Imperial gallon of aluminum sulphate, this figure being largely based upon the results obtained at the experimental plant on the Humber Bay water in Toronto. As a result of practical experience on the mechanical filtration of Lake Ontario water, considerable modification has had to be made as regards the operation of the new plant. Conclusive evidence has been forthcoming from experiments and borne out by actual results, that Lake Ontario water cannot be bacteriologically purified to a high degree by mechanical filtration when only an average dose of aluminum sulphate of one grain per Imperial gallon is applied. The actual purification effected by the drifting sand filters in 1918 was on an average application of 1.027 grains per Imperial gallon, and the results obtained on such a small amount are satisfactory. It has been clearly demonstrated (see diagram) that if a higher dose of alum be applied, a corresponding degree of purification is obtained. The economical question, however, had to be taken into consideration on account of the enormous cost of aluminum sulphate, and when it is considered that during periods of high pollution as much as 2.5 grains per gallon was applied, a definite economy as well as a practical policy of operation had to be adopted.

The summary of conclusions formed are as follows:—

1. That Lake Ontario water can be treated effectively by mechanical filtration.
2. During the year the composition of the water appears to undergo two distinct changes, which make the treatment of the water difficult.
3. That in the summer months more coagulant is necessary than in the winter period.
4. That the purification effected by the drifting sand filters during 1918, upon an average dose of 1 grain per gallon of alum, was satisfactory.

The plant is operated by the Department of Works, Commissioner R. C. Harris being the head of the department, with A. U. Sanderson as superintendent of the plant. The filtration laboratories, under the Department of Health, determine the amount of coagulant necessary. An excellent understanding has always existed between the two departments and close co-operation on the plant has made its operation a simple matter. Our policy of operation as at present defined is:—

1. Treat raw water at all times with sufficient aluminum sulphate to clarify the effluent effectively.
2. Obtain as high a bacterial efficiency as possible on an average dose of one grain per Imperial gallon.
3. Leave final sterilization to chlorine.

In conclusion, I would quote the last paragraph from the official report on drifting sand filters, October, 1918, by Col. G. Nasmith and the writer, which reads as follows:—

"The decision we arrived at when the tender for the mechanical plant was first let, 'That our former conception of a filtration plant was undergoing a material change; that sterilization of the water was the vital thing, from the public health standpoint, but that a filter was essential to clean the water, to keep the sand and dirt out of the water supply, and thereby prevent the wear and tear of machinery valves, taps, etc., as well as prepare the water for efficient sterilization; and that for a great portion of the year only a fraction of a grain of aluminum sulphate in conjunction with a slight amount of chlorine would be essential for filtration, thereby resulting in a great saving in the cost of operating,' has been generally confirmed as a sound one, not only by ourselves, but by sanitarians in civilian and army work the world over." (See *The Canadian Engineer*, issue of October 24th, 1918, page 361.)

In connection with the preparation of this paper, I am indebted to Col. Geo. Nasmith, director of laboratories; A. U. Sanderson, superintendent of the plant; and Messrs. Hannon and Thompson, of the filtration laboratory staff, for their advice and assistance.

SOME ASPECTS OF THE SALVAGE AND WRECKING BUSINESS

By G. Gordon Cottrell
Formerly Manager of The Dominion Salvage & Wrecking Co., Ltd., Toronto

PREVIOUS to the great war, the nations of the North American continent were probably listed as the greatest wasters in the world. With seemingly inexhaustible mines and boundless forests, why should we conserve? Why use the old when the new could be obtained so easily and cheaply? Four years of destruction and expense have taught us the error of our ways. We are now living in an age of reconstruction and utilization. It has taken a great war to awaken us into new activities and make us realize that there is such a thing as a limit to our resources.

With the dawn of a brighter day, the cry has gone forth for reconstruction and production to the utmost. But before we can build the new we must clear the ground of the old, and here is where our experience, so dearly bought by the exigencies of war, should be utilized for peace.

What are Wrecking Companies?

Probably every architect, builder and contractor knows that there are organizations designated as "wrecking companies," but if one familiar with the subject were to question these same architects, builders and contractors as to the functions of the wrecking and salvage organizations, he would receive such a number of diverse and hazy replies that he would have food for many hours' mirth or meditation, according to his mood. Yet there is a reason for this vague and often unfavorable opinion among the building fraternity, as will be shown later.

What is a wrecking company? The replies are interesting. "An aggregation of irresponsible grafters, with no financial backing, trying to get something for nothing," answers the architect. "Wreckers? You mean junk-dealers and one-horse lumbermen," retorts the contractor. And so it goes. Yet this attitude of ignorance and disregard is unfair to construction men, wrecking companies and the public in general.

Recently in conversation with the manager of one of the largest wrecking and salvage companies in Canada, I mentioned some of the replies received to the foregoing question, and his answer is enlightening. "We are neither junk-dealers nor 'one-horse' lumbermen," he said. "Our business is to secure sound, used material, either by wrecking buildings or direct purchase, which we in turn sell at a big saving on current market prices. At all times we maintain a staff of engineers and lumbermen, familiar with building requirements and the requirements of builders. Our stock is composed of good, sound material only; should your requirements happen to be of such a peculiar nature that we cannot fulfil them satisfactorily, no attempt will be made to foist something 'just as good' upon you."

Varied and Interesting Departments

This may come as a revelation to those who, either through ignorance or prejudice, try to deny the usefulness of the modern wrecking company. The gentleman above quoted was referring to one department only—the retail. Yet a large wrecking company contains some of the most varied and interesting departments of any business known. To consider them all in an article of this length would be impossible. However, a brief outline of the main divisions will be attempted.

The activities of any large wrecking company naturally fall into three classifications—namely, tendering and securing contracts; engineering and demolition work; and finally, disposal of material acquired. Obviously, the ability to secure contracts should go hand in hand with the ability to "sell service" and satisfactorily complete the contracts received, but strange to say this is not always the case. As previously mentioned, many of the architects and contractors have a totally erroneous opinion as to the wrecking business, and instead of endeavoring to award their business to the most reliable firm doing the best work, they look for the one which will pay the most. This is another fallacy of the wrecking game, and one which has served to keep out the better class of men from entering the business on a big scale. How can a firm, employing trained men, paying good salaries for qualified superintendents, and with a heavy overhead expense for office upkeep, bid as much for contracts as the little fellow who keeps no books, employs only the cheapest labor, and is bookkeeper, superintendent, manager and company all in one? Architects and contractors have formed their bad opinions of the wrecking companies from these irresponsible pirates.

The Wrecking "Pirate"

The wrecking pirate is the scourge of the business. With no financial backing, and therefore nothing at stake, he is free to come and go, employing the cheapest labor, generally foreign. He has no office, keeps no set of books, pays no taxes, and is everything from office boy and laborer to president of his own activities. If his profits amount to approximately what a large company would pay a capable man in wages, he is satisfied. Yet contractors continue to award their business to these fellows, and then, when they get a poor job, crudely done, in return, they loudly proclaim all wreckers as "irresponsible grafters!" If, when these same contractors have work to award, they would pay more attention to the personality and ability of the parties tendering, instead of considering who will bid the most, they would not only be rendering themselves a service but the wrecking industry as well.

There is still another phase of the business-getting department which will, no doubt, be familiar to many contractors. This is the owner or architect who thinks that estimates should be "cheerfully furnished, free."

Within the past few years, a determined effort has been made by organized contractors and builders to abolish the expensive practice of submitting estimates on speculation, yet many seem to consider that this does not apply to the wrecking contractor. One of the largest items of expense in connection with the wrecking and salvage business is that of "Preliminary Estimating Expense," which annually amounts to thousands of dollars through estimating on work which is never even let.

Cost of Estimating

Many owners seem to feel that wrecking companies should gladly prepare estimates without even the assurance that work will be started, and here, again the wrecking pirate accommodates them, while indirectly increasing the expense. It costs money to send an experienced estimator out to examine a prospective job. Often I have received "rush" letters advising that tenders were desired on a certain job within the next few days. That meant dropping all other work, and perhaps calling in the chief superintendent from some job out of the city. After rushing him to the scene of the proposed work, paying all his travelling expenses, and in addition thereto the time, labor and expense of taking his figures, computing the expense of the job and submitting a tender on time, we were finally advised that the owner had been merely contemplating the work and did not intend doing anything definite until the high prices dropped.

This is no exaggeration. I personally know the owners of a certain building who annually call for tenders as regularly as winter melts into spring. For three years now they have annually called for tenders on a "rush" job, yet the building is still standing and in all probability will continue to do so, at least until the present ownership changes. All this preliminary estimating expense helps to swell the cost of doing business, and it is the larger and more stable concerns who feel it most. Small concerns doing business for but a few months will never have the experience or expense above mentioned, so they submit estimates indiscriminately, with the result that all others must do likewise or run the risk of falling into disfavor.

However, we will assume that our clients mean business, and have awarded us the contract. After the agreement has been signed, the actual wrecking operations begin. No two jobs are the same, so no fixed procedure will suffice. The wrecking contractor must always bear in mind that his

profit comes solely from the resale of the material acquired. He must, therefore, endeavor to carry on the work of demolition with the main object of salvaging practically all of the material, while at the same time remembering that it must be done expeditiously and in a manner satisfactory to the owner or architect. Also, he must use fine discrimination; far better to smash certain sections outright than adopt ultra-cautious methods of salvage and so boost the expense to such a point that the material finally available, costs more than its selling value.

Smashing vs. Scientific Wrecking

Modern business demands speed and efficiency, and this is as true of the wrecking business as any other. The problems of party walls, loads on girders and removal of floors are not for the amateur. It is now generally conceded among the larger wrecking concerns, that only experienced men of brains and initiative can qualify as superintendents, and good salaries must be paid. Even yet, some of the old-timers fight against this tendency towards expert wrecking, but emphatically there is a vast difference between smashing down a building slip-shod and wrecking it scientifically. Scientific wrecking means something. Not long ago I was asked to bid on a job, and the owner, thinking my tender too low, decided to do the work himself. Accordingly, he engaged a few inexperienced laborers, equipped them with picks and sledge-hammers and began. The resulting wreck would have cheered the heart of a dealer in kindling-wood or tooth-picks. Certainly there was some good "wrecking." But when the owner came to sort out the material available for sale, he found so little left that the proceeds did not near compensate him for the expense of demolition! It was simply proof that bull-headed smashing cannot compete with scientific wrecking methods.

While all the larger wrecking organizations maintain yards and warehouses, it is the general policy to sell as much material as possible directly off the job. This benefits both the seller and the buyer; it assists the contractor to clear away his material as the work proceeds, and also eliminates the expense of loading, trucking to the yards, unloading and holding for sale. He can therefore afford to sell for less directly off the job than from stock, although the buyer may not have the same selection to choose from.

As the job nears completion, provision must be made for closing up the work within the time specified in the contract, and all the material is trucked directly to the yards and passed into stock. It then comes under the charge of the yard superintendent, who must be a natural trader and possess a wide knowledge of values, as they relate to all kinds of merchandise. Electrical fixtures and supplies, plumbing material, radiators, boilers, mantels, mirrors, stained and fancy glass, valves, machinery and all kinds of building material pass into his care. Not only must he be able to judge the age and condition accurately, but in addition he must keep in touch with the various market fluctuations, so that he will never be in the unpleasant position of having salvaged material for sale at prices higher than new material would command. A yard superintendent should possess wide powers; he should have full authority, for instance, to lower prices on slow-selling commodities and thus clear them out, rather than fill his warehouse with material for which there is but slight demand through insisting on higher prices set by some executive not in touch with the trade.

Success in Quick Sales

As in all other lines of merchandizing, the success of the retail end of the wrecking business depends on quick turn-overs. Keep the stock moving. As the retail division controls the profit or loss of the business, it demands close attention, and every effort should be made to satisfy customers and treat prospective purchasers with courtesy. This is not always the easiest thing in the world to do, for owing to the pecularities of the business, many of the day's callers are persons "just looking around." They have no definite idea as to what they want, and seem to feel that the yard superintendent should give them several hours of his time, if necessary, simply pulling down material for their inspection. Turning these vague prospects into actual purchasers demands real salesmanship.

In addition to their ordinary facilities for handling lumber, most of the larger companies now maintain sawmills for their own exclusive use. This is something of an innovation to the wrecking industry, but one which has proved most satisfactory. Where a company is doing a large business and taking large quantities of lumber into stock, there soon accumulates a vast quantity in unsaleable sizes.

Generally speaking, a large proportion of the unsold material off contract jobs, remains unsold, simply because it is in large or odd sizes, and forwarding this to the yard simply means stocking up with unsaleable material. The usefulness of a good mill, capable of resawing this timber into saleable sizes is at once apparent.

To be of use, a mill should contain both swing and rip saws capable of cutting the largest sizes of dimension timber. In several instances companies have installed small mills with cheap equipment, but have found to their cost that instead of being assets they are but bills of expense.

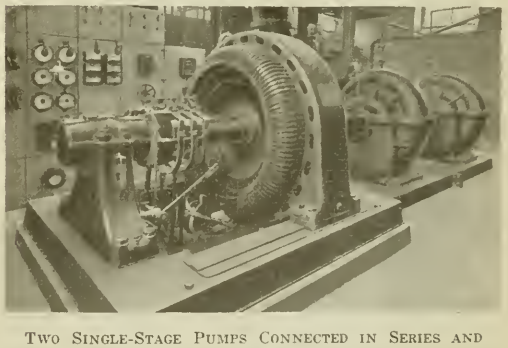
At this stage, one may ask: "What are the possibilities of the wrecking business?" Let me say right here that at the present time there is actual need for a large wrecking organization, and when I say "large," I mean it in every sense of the word.

TEST SHOWS 82.1% OVER-ALL EFFICIENCY OF MOTOR-DRIVEN CENTRIFUGAL PUMP

By R. N. Austin
Manager, Turbine Equipment Co., Ltd., Toronto

THAT the efficiency of centrifugal pumps is still climbing, and that under certain circumstances water works' pumps can be profitably operated with central-station power, is shown by the report of an acceptance test made upon a motor-driven pump at the Minneapolis water works.

In a paper read before the Minnesota section of the American Water Works Association, F. W. Capellen, city engineer of Minneapolis, states that in May, 1911, the city entered into a ten-year contract with the Minneapolis Gen-



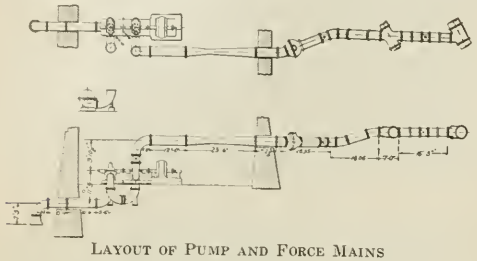
Two Single-Stage Pumps Connected in Series and Driven by Induction Motor

eral Electric Co., now the Northern States Power Co., by which that company agreed to furnish current at 2,200 volts to operate two or more 20,000,000-gal. pumps (throughout this article the word "gallon" means "U.S. gallon"), against a dynamic head of 240 ft., based upon a pumping set of 72% over-all efficiency, at a price of $4 per million gallons pumped, the understanding being that no current would be used between 4.15 p.m. and 6.30 p.m. on week days during the months of November, December, January and February.

In November, 1916, a similar ten-year contract was made with the same company for the operation of a 30,000,000-gal. pump against the same head, and with the same pump efficiency, to be charged for at the same rate, with the provision that at a different dynamic head or efficiency, the price per million gallons should be adjusted accordingly.

It was also specified that the motor to be used by the city should be capable of starting the pump when primed and with the check or gate valve in the discharge closed, and of bringing the pump to full speed without drawing more than 150% of full load current from the source of supply. In 1910 and 1911, two 20,000,000-gal. Worthington pumps were installed, and in 1918, a De Laval pump.

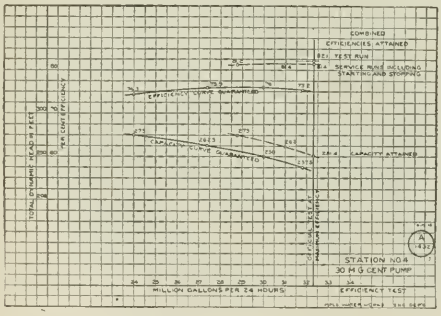
The latter unit consists of a General Electric 1800-h.p., three-phase, slip-ring induction motor directly connected to two De Laval 24-in. single-stage pumps, mounted upon the same base-plate and connected in series. The unit was specified to deliver 30,000,000 gals. per 24 hours, against a total



Layout of Pump and Force Mains

dynamic head of 250 ft. It is installed at pumping station No. 4 in North-East Minneapolis.

In the official acceptance test, the discharge was measured by means of a Venturi meter, the capacity being calculated from manometer readings, while the discharge head was measured by two sets of calibrated gauges and the suction lift by means of a mercury column. The power supplied was measured by three sets of watt-hour meters, calibrated by means of a portable set of standard instruments read during the official test under the conditions of current, voltage and power factor obtaining. The portable set included two single-phase watt meters, one polyphase watt meter, one volt meter, four ammeters, and portable current and potential transformers. All instruments were checked and cali-



Capacity and Efficiency Curves, Showing Results of Test

brated in the presence of witnesses. The test lasted 28 hours. The results were as follows:—

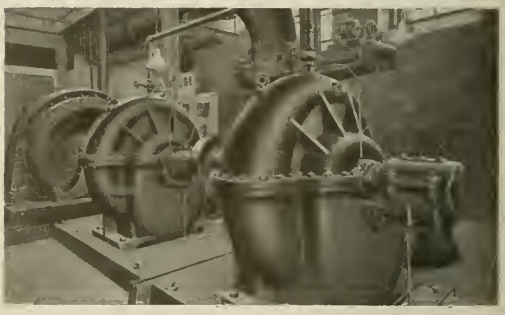
Total pumpage in 28 hrs.	37,719,500 gals.
Rate per 24 hrs.	32,331,000 gals.
Discharge head, average	235.13 ft.
Suction lift, average	16.43 ft.
Total dynamic head, average	251.56 ft.
Kilowatt hours used	36,307.2
Combined efficiency of motor and pump	82.1%
Average line voltage	2,406
Power factor	90.0%
Motor efficiency under test conditions	[illegible]
Slip of induction motor	1.1%
Temperature rise	33.5 degs. C.
Starting current, percentage of full load current	113.0%

The contract provided a bonus of $500 for each 1% of efficiency exceeding 76% when pumping 30,000,000 gals. per day against a total dynamic head of 250 ft. The maximum bonus was limited to $2,400. A penalty of $500 was provided for each 1% by which the efficiency might fall below 76%, and the pump was not to be accepted if the over-all efficiency fell below 72%.

As the accompanying chart shows, 76% efficiency was exceeded at all loads tested, and the average combined efficiency, including the regular starting and other conditions incidental to a varying load in regular service, should not be less than 82.1% by more than 1%. The over-all efficiency of 82.1% divided by the motor efficiency of 95.5% gives a pump efficiency of 85.97%. This is believed to establish a new record.

Service runs extending over a period of three months show an excess of 5% over the efficiencies stipulated in the contract for various heads.

The test was accepted as correct by J. E. Jensen, supervisor of the water works department, and E. C. York, engineer of pumping stations. The foregoing information is taken from the official test of the report by Prof. F. W. Springer, of the University of Minnesota, who was in full charge of the test, so far as the city was concerned.



Another View of the 30,000,000-Gal. Unit

The following operating data were obtained during the first three months after the test:—

Gallons pumped	2,797,490,000
Power cost per million gals.	$3.63
Labor and supplies per million gals.	$2.27
Total cost per million gals.	$5.95
Head, ft.	253.06
Over-all efficiency, per cent.	81.4

Similar records for the first nine months subsequent to the test are as follows:—

Gallons pumped	6,526,350,000
Power cost per million gals.	$3.72
Labor and supplies per million gals.	$1.77
Total cost per million gals.	$5.49
Head, ft.	255.80
Over-all efficiency, per cent.	82.48

Figures are also available from two triple-expansion pumps installed in the same plant in 1903 and 1904, and tested in September, 1904. These pumps have a capacity of 15,000,000 gals. per day each, and on test developed a duty of 162,000,000 ft.-lbs. per 1,000 lbs. of steam, reduction being made for slip. During 1908 the two steam pumps raised practically all of the water for the city—namely, 6,518,000,000 gals. against 250 ft. head. The cost of fuel, using Illinois screenings at $2.07 per ton, was $3.01 per million gals., the cost of labor $3.33, and other pumping costs 35 cents per million gals., making a total of $6.75. The cost to-day, with coal at $4.93 per ton, would be approximately $12.74 per million gals. The low prices which the city realizes on its power contracts with the electric company are, of course, explainable in that the contracts were made some time ago and for a long term.

Canada Must Develop Her Great Fuel Resources

Dependence Upon Supply from United States is National Menace Despite Best Intentions of that Country — International Problem for Engineers and Statesmen— Address Delivered August 22nd at Annual Convention of Canadian Gas Association

By ARTHUR V. WHITE
Consulting Engineer, Commission of Conservation of Canada

APART from the maintenance of the proper morale of the nation and of the sources and distribution of food, there is, I believe, no question involving physical matters which is of such vital issue to Canada as her fuel problem. As some of you know, for many years and whenever occasion has offered, I have been emphasizing the gravity of this problem and the need for taking prompt and adequate national action respecting its solution.

To-day, although having in mind the annual coal shortage again menacing us, I desire, nevertheless, to treat our subject more in its broader aspects.

Although we have had coal shortages in Canada and a measure of accompanying distress, yet, after all, the great mass of our people have been practically unharmed by the stress of coal conditions. It may not always be so. Through failure to deal adequately and in a broad, statesmanlike manner with her national coal problem, Canada courts trouble and, I believe, may yet experience such a "pinch" with respect to her fuel supplies as will seriously affect her economic welfare. Is it not of the deepest significance that Herbert Hoover in the early part of this month, speaking as head of the International Relief Organization of Europe, stated that "the fate of European civilization now rests in the hands of the coal and coal mine owners of Europe to an equal if not a greater degree than in the hands of the producers of foods and supplies during the next year?" Mr. Hoover contends that only greatly increased coal production and an improved organization for its distribution can save Europe from disaster during the coming year.

As already mentioned, we in Canada have been comparatively free from experiencing the keener distresses of coal privation. It is true that during previous coal shortage many people have had to get along from hand to mouth. Coal has had to be doled out in small lots and in 1917-18, I understand, was even expressed in 100-lb. parcels to effect relief in certain localities, and so on; but speaking generally, we, nationally, have not had anything like the distress respecting fuel which has been extensively experienced by European countries.

Some European Coal Conditions

Let us begin by briefly surveying certain present world coal conditions, and as we do so kindly bear in mind one fact, namely, that the United States, which furnishes us with so large a part of our annual coal supply, has now become much more closely associated with world markets and world conditions. She is rapidly assuming a premier position as a coal exporter, and older European countries are eagerly looking to her for "first aid." In our survey it will be appropriate to consider coal statistics as applicable in 1913—just before the war.

The countries of western and southern Europe even in normal times are badly circumstanced for fuel. France, Italy, Norway, Sweden and Portugal have been largely dependent for their coal on Great Britain. In 1913, Britain supplied for export to continental Europe about 50,000,000 tons of coal of which France took 20,000,000 tons, Italy 9,650,000 tons, Sweden 4,569,000 tons, Norway 2,300,000 tons, Spain 3,650,000 tons, Denmark 3,030,000 tons, Holland 2,010,000 tons, Portugal 1,360,000 tons, other Mediterranean countries 3,500,000 tons. In addition Great Britain sent about 9,000,000 tons to South America and 5,000,000 tons to other parts of the world.

Britain's exported coal before the war constituted in point of value 8½%, and in point of weight 7½%, of her total export trade. This coal serves as ballast for outgoing boats and enables them to return to home ports with raw material and foodstuffs. It is evident therefore what prime bearing Britain's coal industry has to her export trade. What are the conditions in Great Britain to-day? At the present time, owing to exhaustion of stocks, to shorter hours of labor, to decrease of transportation facilities, to strikes —including the recent coal miners' strike, alone involving 250,000 men—Great Britain's annual rate of production has fallen about 70,000,000 tons short of pre-war conditions. If the restrictions on her home consumption are removed, it has been estimated that she may have 7,000,000 tons of coal for export during the coming year. It the restrictions are maintained, this amount may be brought up to 28,000,000 tons. But even if all this coal were shipped to western and southern Europe, there would for these areas still result a deficiency of more than 25,000,000 tons. This leaves out of consideration South America and other portions of the world previously supplied by Britain.

Coal Conditions in France

In France, the coal mines destroyed by the Germans—both wantonly and for military necessity—formerly produced 20,000,000 tons per annum. French engineers state that it will take from two to five years to rebuild the operating equipment, and ten years to completely restore the production rate of these mines. France, however, will be able to increase her fuel supplies owing to the occupation of the Sarre District. But she has to replace her former importation where deprived of same. France still faces serious coal shortage.

Italy's condition with respect to fuel throughout the war period has been desperate. In 1913 she was producing less than 750,000 tons of coal per annum and, as we have seen, was importing from Great Britain some 10,000,000 tons. During the war, at great expense, she was able to increase her home production of an inferior grade of fuel by about 1,000,000 tons. This month Italy has ordered that 300,000 tons of her shipping sail for American ports to return with coal.

In Germany, fuel conditions are represented to be exceedingly bad. On August 6th, at the coal conference of experts from all parts of Germany to devise means for increasing the production of coal "so that Germany will not freeze or starve during the coming winter," the chief result arrived at in the preliminary meetings of the conference has been to emphasize the fact that the German situation also is desperate. It was recognized, however, that hard and intelligent work alone will contribute to alleviate the distress. Avenues for effort are being determined. Germanly has succeeded in inducing France to admit that the supplying of her demand of 40,000,000 tons of coal annually would be a physical impossibility; and Germany further represents that she cannot hope to supply even enough coal for her own most urgent needs. She certainly will be hard pressed to find surplus coal with which to discharge, as she must first do, her obligations to France. German counsellors have recommended that it will be best to sacrifice some of their national forests. Some industries which formerly used coal as fuel are now attempting to use wood. It is interesting to observe that in the tentative German plans for priority of those who are to receive coal it has been laid down that the first claim will be for the railways in order to insure transportation of food. The claims of industry will come next, in order that credit may be created by the production of articles of commerce. Next, the mass of the people will receive coal for heating and cooking. It was com-

mented that the prospects for the latter class are exceedingly slim.

The German Minister of Economics, in the course of the recent debate on the coal situation, told the National Assembly of Germany that the government was ready to import American coal for industrial purposes, and he indicated that it might be necessary this coming fall to discontinue passenger traffic in order to use all available equipment to haul coal and move crops.

Countries Coerced Respecting Coal

It is not necessary to extend our survey into the coal conditions of the smaller European countries. Norway, Sweden, Denmark, Holland and Switzerland, though neutral during the war, found themselves practically dependent upon the warring nations for coal and had to submit to the dictation of terms upon which that necessity would be supplied them. Both Great Britain and Germany released coal to these countries in exchange for food. Germany supplied Holland with coal on condition that food, especially vegetables and meat raised on Dutch soil be sent to Germany; and you may recall that Germany's demand for supplying Switzerland with 200,000 tons of coal per month was gold at the rate of 40,000,000 francs monthly for nine months. Without touching further upon the stressful conditions in these smaller countries, the comments already made, especially respecting coal conditions in Great Britain, France, Italy and Germany, clearly prove the very serious conditions existent in European countries—and this, may I add, at a time when every effort is being made to re-establish mercantile and other conditions on bases approaching what they were prior to the war. Most assuredly this means keen competition for any available coal, and in this respect the governments and peoples of Europe are looking for a maximum of relief through coal shipments from the United States.

United States' export coal is a phase of the world coal problem in which Canada is deeply interested, because she yearly imports from 15,000,000 to 20,000,000 tons of coal—anthracite and bituminous—from the States.

Embargoes May be Necessary

Now, in the statement I am about to make I wish to emphasize that it is in no sense my intention to suggest that it is, or that it would become, the arbitrary desire of the United States to deprive Canada of the coal which at present is so necessary to life in this country. Of course with their co-operation, we have in a measure become dependent upon their coal fields, and it will be expected that the States, in all fairness, will facilitate any necessary future readjustment connected with Canada's fuel supply. It is important, however, to take cognizance of the fact that a nation, pressed by the demands of its own people, may be compelled, under certain conditions, to deprive other nations—in part at least—of even the necessaries of life until the needs of its own citizens are met. No country can be expected to send out of its own confines that which is essential to the very existence of its own people. Personally, I do not believe that the United States, or any other country with a large outlook on present world affairs, will allow whole nations, especially those with whom they have been allied, to suffer direst distress with respect to fuel without seeking to alleviate it to the greatest possible extent.

When communities in Canada and the States during previous coal shortages have been in need of coal, certain communities adjacent to other sources of supply, such as wood, softer grades of coal, etc., were compelled to use these in order that the supplies elsewhere available could be distributed to those in greatest need. Correspondingly, it would not be surprising if a country like Canada, with vast fuel resources, were directed to speed up its utilization of its own fuel, and would not be left undisturbed, so to speak, in its enjoyment of burning what is now one of the luxuries of the world, namely anthracite from the coal fields of Pennsylvania.

Let us next note what in general are the conditions in the great republic across our borders. Coal production in the United States has dropped substantially behind what it was during the war years. If the present rate of production of bituminous coal is maintained for the remaining twenty-one weeks of the coal year, the production will about equal the output of 1913. The production of anthracite is increasing over what it was a few weeks ago, but it is still short of the demand. The coal stocks of the United States have been depleted. There is great demand for transportation. Car shortage will accentuate itself with the demand for cars to move the grain crop. The exit of miners back to Europe, serious strikes, and other factors, have contributed to curtail coal production and distribution in that country. If more serious strikes should occur in the States, it will tend to make the supplying of coal to other countries, including Canada, still more precarious. Canada cannot afford to overlook how her own interests may at any time become involved by serious coal strikes in the United States. These strikes are an ever-present menace. Speaking in the United States Senate on August 8th, Senator King, of Utah, stated that he had heard "that there was a program to organize a great strike now, to tie up the transportation system and take over the railroads, then next winter, when the people were shivering for want of coal, organize another strike in the mines, cut off the country's fuel supply, and take over the mines." The senator expressed the hope—and which we all share—that government authority will be able to prevent such extremes being reached. I simply quote the senator's statement as indicating possibilities which he thought of sufficient importance to bring formally to the attention of his colleagues. It is clear, therefore, that coal production in the States must necessarily fall short of meeting even the most pressing demands.

Common Aims and Sympathies

Canada is indeed exceedingly fortunate in being neighbor to a country whose national aims and sympathies are so akin to its own. During the war both countries have manifested special interchange of courtesies. In the past coal shortage, for example, the Fuel Controller, Dr. H. A. Garfield, announced that recognition of Canada's needs for coal would be on the same basis as though she were one of the states of the Union. Our own Fuel Controller, C. A. Magrath, rendered signal service to both countries. I like to recall the sentiment manifested by our neighbors when great distress has arisen due to necessity corresponding to that begotten of the Halifax catastrophe—and such sentiment has been reciprocated by Canadians when conditions have been reversed. The governor of Massachusetts telegraphed assuringly, "The people of the Commonwealth of Massachusetts are ready to answer any call that may be made upon us. Massachusetts stands ready to go the limit in rendering every assistance you may be in need of." The Governor of Maine telegraphed, "Any help Maine can give is yours," while many others sent corresponding messages. These sentiments cannot better be summed up than in the inspiring message sent by President Wilson to

"His Excellency the Governor-General of Canada:

"In presence of the awful disaster at Halifax the people of the United States offer to their noble brethren of the Dominion their heart-felt sympathy and grief, as is fitting at this time, when to the ties of kinship and community of speech and of material interests are added the strong bonds of union in the common cause of devotion to the supreme duties of national existence."

Canada Must Bestir Herself

Obviously, so long as such sentiments govern men's actions, the people living on this continent cannot be deprived of that which is essential to their existence. Nevertheless, with the growing scarcity of coal, the United States, no matter what her good will or desire towards Canada may be, may not be able to cope with her own and with the prevailing world need. There is no doubt that in the spirit and disposition manifested in the statements just quoted our neighbor will see that Canada is fairly dealt with. We should not, however, trespass unduly upon friendly accommodation.

As we have now seen, the present need of coal is urgent and world-wide. If the United States, either in the interests of her own people or in the interests of the peoples whom she may conclude to be more needy than Canada, should decide that it is more necessary to supply such nations with coal, with the result that Canada's normal supply be substantially reduced, who may reasonably find fault with such a course? Even apart from governmental action, could anyone find fault with the United States coal merchants if, in their efforts to capture as much as possible of the 160,000,000 tons of annual international coal trade, they sought to deal where they could do so most advantageously? If, under such circumstances, Canada be judged to be not the best market for the United States coal dealer, from whence does Canada hope to supplement any substantial lack in supply of her coal demands? Let me emphasize the fact that there is nothing new in these possibilities so far as Canada is concerned. The handwriting on the wall has for years been legible. The whole problem has been one calling for ablest statesmanship and not for political or other temporizing and expediency. The problem will never yield to any makeshift policy. I have often marvelled that so little has actually been accomplished with respect to its permanent solution.

No Menace More Serious

It is gratifying to realize that serious effort is now being made towards the development of our lignite and peat resources; also, towards the increased utilization of our coal fields in the east and west. I understand that work preparatory to the construction of the carbonized lignite briquetting plant to be erected under the direction of the Honorary Advisory Council for Scientific and Industrial Research for the Dominion government is being pressed ahead with despatch. This is to have a capacity of 30,000 tons of briquettes per annum. It would take over 600 of such plants to replace our present coal importation from the States. However, we are very glad that this start has been made.

From the foregoing comments it is evident that an intelligent outlook upon world conditions shows scarcely any aspect of them to be of more serious moment—immediate or prospective—than this coal problem. During these warm days we should be careful to take our counsel and warnings from an intelligent outlook upon these conditions and what they betoken for the future, rather than from our feelings based upon the present state of the thermometer. Whether conditions of curtailed fuel supply for Canada be delayed from materializing this coming winter or next winter, or until some time in the future, nevertheless, as I stated before, I am firmly convinced that there is no menace to Canada's economic and general welfare at all comparable to the fact that she is at present so largely dependent upon a foreign country for her fuel needs. Without this foreign supply, Canada most assuredly would be put to desperate straits. Gentlemen, is not the fuel problem of this Dominion one of magnitude and great gravity?

Canada's Water-Power Heritage

Canada, it is true, is richly endowed with water-power, but she can never depend upon this asset as a sole source of heat. We have about 19,000,000 estimated 24-hour low-water horsepower, of which less than 2,500,000 h.p. has been developed. By no means may all the water-powers be economically developed.

For many years past I have been emphasizing the comparatively limited use which can be made of electric energy as a wholesale substitute for coal for heating—including the heating of buildings. There is no use whatever entertaining hope that hydro-electric energy as a heating agent may become an adequate substitute for coal for the citizens of Canada, and consequently a realization of this fact will facilitate the concentration of effort upon sources from which real relief may be derived.

What, then, is to be done? In a word, we must develop our own coal reserves. Considering the country as a whole, Canada in respect of quantity, quality and accessibility for mining purposes, possesses coal deposits which compare favorably with those of the greatest coal mining countries of the world. Speaking in round numbers, she has nearly 1,000,000,000 tons of semi-anthracite coal, 315,000,000,000 tons of bituminous coal, and 10,000,000,000.000 tons of sub-bituminous coal and lignite.

I shall not dwell on these enormous reserves. It seems out of place to emphasize how much we have latent when alongside of it we are not able to show how beneficially these assets are being used both for our own support and for the assistance of other needy nations. When the population of the prairie provinces are insured against yearly fuel shortage, we shall be more interested in hearing emphasis laid upon the enormous fuel reserves of these provinces; and when Canada produces more than her present amount of 2% of her total annual oil consumption we shall be more interested in hearing emphasis placed upon the statement that we have the biggest oil fields in the world.

Development Only Sane Policy

Canada's only sane policy is to develop, and that as rapidly as possible, both her own fuel and power resources, and by co-ordination of transportation and other cognate agencies to provide for the distribution and storage of fuel in all communities of the Dominion. In some respects it is more important to move coal and have it adequately stored and distributed throughout Canada than it is to remove the grain out of the country.

In this connection may I comment that we have heard so repeatedly about the necessity of laying in our coal supplies early that I have wondered why no provision has been made to aid that large proportion of the wage-earning population, who covet the ability to lay in their coal early, but who are unable to finance the proposition. The agriculturist is not only counseled to market his grain but governmental and financial agencies make exceptional provision by way of furnishing funds and credit to facilitate grain-marketing operations. Does it not seem as though some corresponding provision, with resulting insurance to the stability and advancement of the country, could be provided in connection with the laying in of the annual coal supply?

In concluding may I digress a moment, for there is one aspect of this fuel situation which I conceive to be of essential importance, and I feel it desirable just to mention it. In so doing I know you will not feel that I am seeking to impose upon you any view foreign to the main theme of our discussion.

Human Power Limited

A few years ago I attended an irrigation conference in western Canada. At that time great development was taking place in the irrigation areas, and in the enthusiasm of these circumstances the official program of the conference bore this motto: "Intelligent men no longer pray for rain—they pay for it." At the time I felt that this suggested an ill-advised spirit in which to undertake irrigation or any other work. Probably those who selected the motto did so somewhat unwittingly and did not stop to consider what it may imply. Man certainly could pay for the digging of the ditches and for the construction of other physical structures incident to irrigation development, but man does not own the water nor can he, by payment, command the rain to replenish it.

For a number of years my work in London took me past that busiest spot in the world—the Royal Exchange—and I used to observe upon its pediment the motto selected by Prince Albert from the Scriptures of Truth: "The Earth is the Lord's and the fulness thereof."

Now, what I wish here to suggest is that in any problem, especially in one of the magnitude and seriousness of the fuel problem of Canada, we cannot afford to deal with it solely on the basis that we, of ourselves, are alone sufficient best to solve it. The Creator has placed coal and other resources in the earth beneficently to serve the needs of man, who, of himself, has not the control over all essential factors germane to these resources nor the wisdom how best to dispose of them. If, for example, man could simply have paid for the rain or its equivalent, we may assume that we would not be experiencing the distressing conditions of dry-

ness which this season have existed over extensive areas upon which we have stimulated settlement in our northwest. Correspondingly, I wish to suggest that in the development of Canada's fuel resources for the need and general benefit of the people there certainly is required more wisdom than has hitherto been manifested in connection with this problem, and this wisdom, I believe, concurrently with our own efforts and in fitting humility, must be sought and received from the One to whom, as the motto just cited states, belongs "the earth and the fulness thereof."

Gentlemen, you operate in a great and unique field which comprises the effecting of economies by subjecting raw coal to such manufacturing processes as will save the valuable by-products and at the same time produce, even from inferior grades of coal, a satisfactory and clean-burning fuel. It is within your province also to aid in effecting a proper co-ordination of the uses of electricity, coal and gas, according to their respective spheres of most efficient use. This oftentimes will result in a greater utilization of gas. Those in the forefront of the gas-producing industries are justified in looking forward to the greatly increased use of this commodity, and to the fuller recovery of by-products. Your contribution to the solution of the national fuel problem of Canada is invaluable. Your field has an ever-extending horizon. I trust you will all find it a truly profitable one for the enthusiastic exercise of your talents.

RECENT PUBLICATIONS

DEPARTMENT OF LABOR.—Report of the Department of Labor, Ottawa, for the fiscal year ended March 31st, 1918; 46 pages and cover, 6½ by 9¾ ins.; contains the reports of the director of coal operations and the registrar of boards of conciliation and investigation.

SUIT FOR INFRINGEMENT.—The Portable Machinery Co., of Passaic, N.J., manufacturers of the Scoop conveyor, have issued a circular claiming that another concern has marketed an imitation of the Scoop conveyor, and stating that a suit is now pending for infringement of rights.

MAGANESE BRONZE CASTINGS.—Catalogue issued by the American Maganese Bronze Co., of Holmesburg, Philadelphia, Pa.; 3¾ by 9 ins.; 24 pages; illustrated. Special reference is made to maganese bronze valve stems and maganese bronze runners for hydraulic turbines.

ELECTRICAL PRECIPITATION.—Circular 7,375 issued by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., describing the recovery of valuable material from smokes and gases; 24 pages and cover; 8½ by 11 ins., printed in colors on coated paper and well illustrated.

MINERAL PRODUCTION OF CANADA.—Annual report for the calender year 1917, of the mineral production of Canada, by John McLeish, head of the division of mineral resources and statistics and acting-director of the Mines Branch, Department of Mines, Ottawa; 258 pages and cover, 6½ by 9½ ins.

CONSERVATION IN 1918.—Address delivered February, 1919, at the annual meeting of the Commission of Conservation by James White, assistant to the chairman of the Commission of Conservation of Canada; reprinted from the tenth annual report of the Commission; 88 pages and cover; 6½ by 9½ ins.

STANDARD APRON CONVEYERS.—Catalogue No. 258 issued by the Jeffrey Manufacturing Co., Columbus, Ohio, describing all standard apron conveyers both of steel and wood flights. This catalogue contains 75 pages and gives general dimensions and other important data of interest to prospective purchasers.

PERFORMANCE OF COLLIERY PLANTS.—Reprint of article on the performance of colliery steam boiler plants and the saving to be obtained by their reorganization, by D. Brownlie, published in "Engineering," London, Eng.; 16 pages, folded table and cover; 7¼ by 9¾ ins. Issued by Brownlie & Green, Ltd., Manchester, Eng.

CLASSIFICATION OF THE CIVIL SERVICE.—The King's Printer, Ottawa, has published the report of transmission to accompany the classification of the civil service of Canada by Arthur Young & Co. This forms a booklet of 82 pages and paper cover, 6½ by 9½ ins. The report states that "it describes schedules for the classification of positions and the standardization of compensation, explaining their need, basis, and the use and method of their preparation, and including a discussion of the problem of the personnel in the Civil Service of Canada, with recommendations for a comprehensive employment policy and plan."

ARCHITECTS MEET IN TORONTO

THE annual convention of the Ontario Association of Architects opens at 9 o'clock this morning at the Engineers' Club, Toronto. The first item on the program is a meeting of the council. At 10 a.m. the first business session starts. It will be followed at 1 p.m. by a luncheon at the King Edward Hotel. After the luncheon there will be a discussion on the viewpoint of the public in regard to the architectural profession.

At 3.30 p.m. a discussion of the legal status of technical professions will be opened by J. P. Hynes, architect, Toronto, and Harry G. Acres, hydraulic engineer of the Hydro-Electric Power Commission of Ontario, who is chairman of the joint committee on technical education. This subject will be followed by a discussion on the use of the term, "registered," in connection with Canadian architects, the discussion being introduced by Ralph Shepard.

At 7.30 p.m. the members of the Ontario Association of Architects and of the Royal Architectural Institute of Canada will visit the Royal Ontario Museum of Archæology as the guests of Prof. G. T. Currelly, director of the museum.

At 9 a.m. to-morrow, October 3rd, the council of the Royal Architectual Institute will meet, and at 9.50 a.m. the twelfth general annual assembly of the institute will be opened by an address by the president of the Ontario Association of Architects, with response by the president of the Royal Architectural Institute.

After routine business, there will be a discussion at 10.30 a.m. on architectural education, led by Prof, Ramsey Traquair, of Montreal, and W. D. Cromarty, of Ottawa. At 1 p.m. there will be a luncheon at the King Edward Hotel, with round-table discussions by Dr. H. J. Cody, Minister of Education; Sir Robert Falconer, president of the University of Toronto; and C. H. Mitchell, dean of the Faculty of Applied Science of the University of Toronto.

The luncheon and discussion will be followed at 3 p.m. by a motor drive around Toronto, and at 7.30 p.m. by a public meeting at the Art Museum, 26 Grange Road, Toronto, to view an architectural exhibition. There will be a popular address by Mrs. H. B. Dunnington-Grubb.

At 9 a.m., Saturday, October 4th, there will be a joint meeting of the Ontario Association of Architects and the Royal Architectural Institute of Canada, with an address on "Town Planning Acts and Their Results," by Nolan Cauchon and Thomas Adams; on "Housing," by W. D. Cromarty and James Govan; and on "War Memorials Considered Aesthetically," by Prof. P. E. Nobbs, of McGill University, Montreal, and Herbert E. Moore.

At 1 p.m., Saturday, there will be another luncheon and round-table discussion at the King Edward Hotel, and at 2 p.m. a meeting of the Ontario Association of Architects for the election of officers, followed at 3 p.m. by a meeting of the council of the Royal Architectural Institute of Canada for the same purpose.

The Royal Architectural Institute of Canada is a federation of the Architectural Institute of British Columbia, the Alberta Association of Architects, Saskatchewan Association of Architects, Manitoba Association of Architects, Ontario Association of Architects and the Province of Quebec Association of Architects. The honorary secretary is Alcide Chaussé, of Montreal.

RECONSTRUCTION OF SMALL WATER-POWER PLANTS*

BY RAY KINGSBURY HOLLAND
Consulting Engineer, Ann Arbor, Mich.

DEVELOPMENTS that may be classed as small water-power plants, with heads ranging from 8 to 20 ft. and with a contributary stream drainage area of 100 to 500 square miles are principally for flour and feed mills, but there are a large number of small hydro-electric developments, both private and municipal, and water works pumping plants driven by hydraulic turbines.

The owner, in looking over a water-power development that had been constructed prior to eight or ten years ago, generally feels, and correctly so, that the plant can be improved, but he is usually at a loss as to just how to go at it. He knows whether or not his present plant is sufficient in power to carry the usual load he imposes upon it, and he knows for what seasons of the year he is very short of water, and what seasons he has plenty of water, and approximately the range of head that prevails. He knows that the turbines are old and is aware that if he should purchase new wheels similar to those installed, he would undoubtedly receive more power; but when he makes an examination of the turbines, he finds that the replacement of perhaps a broken gate and a little lining up of the shafts will give him, in appearance, a turbine which looks as serviceable as a new one. The consequence of all this is that while he has a feeling that the plant ought to be reconstructed, he has not been satisfied that the reconstruction will show him a particular gain for his investment.

Engineer Must Study Conditions

If we, as engineers, could be called in to examine such a plant, with the idea of putting before the owner concretely what his needs are and what the costs will be, we find that we must start deeper in the problem if we will obtain for the owner any particular advantage in reconstruction. We must go back first to study his plant and check up as to whether the original installation was suited to the stream and the purposes to which he proposes using it.

The question of whether the machinery installed is suitable or not for the speed at which he desires to operate and for the prevailing head, we can pass up for the present until study of the other considerations influencing the development is completed.

The stream flow is naturally of the most importance to the development and its determination is usually our first consideration. The stream flow at a particular site may be determined by steam gaugings or observations of flow over a dam of uniform crest and the like, but to be of any value the observation must extend over a considerable period of time. It is generally the case that there are no records of the particular stream at the particular site being considered. The engineer must then draw upon his accumulation of stream flow data of other streams, in the neighborhood if possible, having similar drainage basin characteristics, in order to estimate the probable flow of this particular stream at the site considered.

Application of Known Data

The judgment used in the selection of the records of known streams and their applicability to this drainage area is an all important factor in this approximation of stream flow. It is to be particularly noted that three or four stream observations at this site, unless they be selected at extreme conditions and at average conditions, are of very little value in arriving at what might be the average flow of the stream in the course of a number of years.

Assuming that we have arrived now at the average flow of the stream, the next point to consider is the head under which the turbines will operate. The head, as we use it, is the distance from the average water surface level in the

*From paper presented to the Michigan Engineering Society.

wheel pits to the average surface level of the water in the draft pit; or in case a curved draft tube is used discharging the water down-stream, to the water surface at the exit of this draft tube.

Factors Influencing Head

The two particular factors, therefore, influencing the head are the level of the water surface of the pond and of the tail race. The pond level is subject to variation due to the stream flow being less, or in excess of that used by the turbines. The excess is taken care of usually by flood gates or spillway, and the pond is generally at its highest level during such periods. When the river flow is less than the water used by the turbine, there is a draft on the pond and the water is pulled down.

The highest stage that the pond may be carried is generally controlled by the flowage rights and in each case requires investigation as to whether there are physical limitations to a higher pond stage, that is to say, whether the raising of the pond level will cause very large flat areas to be flowed, or is prevented by the physical conditions at the dam or plant. If no such limitations are present, it is usually advantageous to the owner to acquire flowage for a higher pond level, and it can be usually shown that this flowage is worth much more to the owner than he has assumed it to be, when he has considered it worth only the value of the adjacent property for farming purposes.

The tail water level is generally the level of the natural river before the development, and if there are no obstructions immediately below the plant, usually no particular advantage to the head may be gained by improvement to the tail race, such as deepening and the like.

Effect of Raising Pond

There is one factor usually present in the question of raising the pond that is little understood, and that is the question of backwater, meaning by backwater, the increase of the water stage due to the construction of the dam, over the water stage of the natural stream. With any dam constructed across a stream and with a normal stream flow and the pond level carried at the crest of the spillway, the maximum backwater effect will occur at a point located approximately at the intersection of planes tangent to the water surface of the pond and to the water surface of the stream above the pond. If the pond surface is now maintained at the crest of the dam, with increasing stream flow, the backwater effect will usually become less and with decreasing flow becomes greater at this point, but if the spillway is of ample discharge capacity so that the head on the spillway for the overflow, increases at a lesser rate than the normal river stage for the same increased flow of water, the backwater effect at the point first considered becomes no greater with this increaseing flow, when such increase of flow is wasted over the spillway.

While it may be found that the amount of the backwater effect is less with the increased flow being wasted over the spillway, at the same time it may be also found that the backwater effect reaches further upstream. Usually this is of little importance because of the small amount of the increase of river stage, but should this back against another water-power development this small amount of backwater effect frequently causes a large amount of trouble.

The engineer should make a careful study and endeavor in such cases to clearly present the problem so that it may be understood by the interested parties and if possible form the basis of an agreement whereby the lower development may back water against the upper under the extreme conditions, thereby obtaining between the two plants the maximum power obtainable from the river.

Uses for Power

The use to which the power is to be put is our next consideration. If for milling or manufacturing, it is generally for 9 or 10 hours each working day, sometimes for the 24 hours. If for hydro-electric developments with a single plant, power may be required for 24 hours but sometimes is required for only 10 or 12 hours, this usually where commercial lighting only is served, or for lighting and pumping where a reservoir or elevated tank is available.

In reconstruction, this matter is more or less definitely settled by the past performance at the plant, and the gain in power output from the higher efficiency usually provides a margin that insures the turbine being of sufficient capacity to care for peak periods.

Where a change in the length of period of operation or additional load is contemplated, particular attention must be given to the probable power obtainable at the site in order to advise whether the development will permit the change.

The capacity of the pond (in acre feet) is the factor which determines the ratio of the maximum power of the daily period to the average 24-hour power available from the river flow.

An acre foot being the quantity in an acre of water 1 ft. deep, the capacity of the pond is then dependent upon the product of the average area and depth of draft to which the pond may be drawn. The area being fixed by physical conditions the capacity is directly dependent on the draft. But the draft on the pond reduces the head on the turbine and results in a power loss that increases at better than three halves power of the ratio of the change of head, consequently a minimum draft is desirable. From practical considerations 5 to 8% of the head may be permitted as the draft on the pond.

Pulling Down the Pond

This question of pulling down the pond is one that the engineer should cover thoroughly with the owners of the development, as the usual rule is to find that the operators of the plant pull the head excessively at the beginning of the summer season and it is not given an opportunity to recover again until the fall rains, resulting in shortage of power during the whole summer. We find this condition usual with municipally operated plants and only little less frequent with privately owned plants. One plant, a year or so ago, whose average head is 15 ft., pulled the pond in the first three summer weeks to between 9 and 10 ft. and operated at these low heads all summer by generating some auxiliary power by steam and cutting short the street lighting period. The plant capacity at these lower heads for the same amount of water was less than one-half the capacity at the full head, and had the auxiliary power been supplied when the head started lowering, auxiliary power would probably only have been required the first week of the summer period. Best rule is perhaps to have the pond brought to normal stage at least once in 24 hours.

The ratio of the turbine capacity to the normal stream flow is determined as is shown above from the considerations of the load to be carried and the size of the pond, and the permissible draft on the pond.

Deciding Capacity of Turbine

We have now gotten the elements together that permit our decision as to the capacity of the turbines to be installed. By reference to our determination of the river flow we can select the point from the expected average annual stream flow that will give us the most economy in the relation of the cost to the power obtained. Naturally, if the installation is made equal to the minimum continuous flow, we would obtain the most power for the least money invested in machinery only, but because of the investment in the powerhouse, dam, flowage rights, etc., we usually find that the economical development in most cases will occur at a point in the stream flow that may be said to just above the average normal flow of the stream. Applying to the quantity of water flowing, we can obtain the theoretical 24-hour power of the development, to which must be then applied the factor previously determined by the use to which the power is to be put, resulting in the theoretical capacity to be installed.

If this be taken roughly at 70% to 75% efficiency, the approximate plant capacity is obtained, which may be checked against the power required for the operations, and adjusted, if necessary, to meet the actual conditions that prevail. This adjustment however, is usually at a sacrifice of the power that the stream produces. This is true from the fact that if a much larger installation is made, the effici-

ency of operation is less because of the necessity of running at small gate openings for longer periods, and if a much smaller turbine is installed, the possibility of not being able to carry the peak load becomes pertinent.

Selection of Turbine

As is generally known, a turbine of a given runner characteristic will have a practically fixed speed for a given head for each of the manufacturer's size of turbines, and it is necessary here to make adjustments and concessions between the capacity of the wheel or wheels and speed at which these wheels are to operate. The higher the speed, of course, the smaller the individual turbine. With hydro-electric developments this problem is usually complicated further by the fixed speed requirements of an alternating current generator, and with any development it is usually necessary that the speed selected be maintained constant, notwithstanding the variations of head that will occur.

It is, therefore, necessary that the engineer, in making the selection of the turbine, be conversant with the type characteristics and the standard capacities of the manufacturers' developed turbines and co-ordinate the number of turbines and the speed to the total capacity which is now practically fixed, to obtain the maximum power under the variations of head and load usually prevailing.

Aside from the runner characteristic of the turbine to be selected, some consideration must be given to the mechanical construction of the turbine, so far as relates to the shop work, strength and rigidity. These being more important where the turbine is to be operated on an extremely variable load, with the gates controlled by oil pressure governors.

Having selected the turbine a computation of the probable annual output may be made, which combined with the fixed and operating cost forms a criterion from which the owner may arrive at a decision as to the necessity of reconstruction.

Details Affecting Operation

There are numerous minor details now to be considered relating principally to those affecting the operating of the plant.

If the power is to be used for milling and for general manufacturing purposes, the so-called friction governors are generally satisfactory, but if for hydro-electric work, it is usually necessary to have the more sensitive oil pressure governors. The question of bearings and the supporting of the runner and shaft is more important than the consideration usually given, because these points are the ones continually under the observation of the operator, and where no trouble is experienced, he has faith in his machinery and does all in his power to keep it in first class condition, while, if he is continually having trouble with alignment of shafts and with bearings, he is very apt to become convinced that the entire equipment is no good, with the result that he does not give it the attention that it should have to deliver the power of which it is capable. This is a point that is frequently lost sight of, and is particularly important one from the owner's point of view.

The structure to house the equipment is controlled primarily by space required for the machinery on the operating floor and by the requirement of ample water passages to and from the turbine, and secondarily, by the relation of the structure to existing structures, bridges, the channel, and the like.

The power-house construction itself does not differ materially from other first class constructions except the requirement of water tightness, rigidity of construction and the necessity of providing that no settlement takes place. Special caution must be observed, however, that foundations are protected against undermining, as a small spurt of water at a critical point will very quickly wreck the best hydraulic structure.

The shape of the flume and location of the turbine in the flume requires special study, if for any reason that water area to the turbine is to be restricted. Trash racks and easily operated wheel pit gates are necessities to a well designed plant, particularly the desirability of easy and quick operation of the head gates by the operator, as they serve as an inducement to him to the making of periodical inspections of the turbines and under-water mechanisms.

Unless the head is very low the turbine is invariably placed above the tail water level, making the question of the draft tube a particularly important one, and not of easy solution even when the engineer has wide lattitude in his design. When space is restricted, the design of the draft tube must be governed largely by the designer's experience and the results obtained from other constructions where conditions analogous to those under consideration are present.

Examples of Plant Reconstruction

As a result of the practical application of the principle of making a study of the small plant reconstruction along lines very similar to those followed with a larger installation, I would cite the following reconstructions of this type made by our firm in the last couple of years:—

In a hydro-electric plant in the northern part of Michigan, drainage area about 100 square miles, normal head about 14 ft., the old installation was a single turbine some 20 years old, rated at 170 h.p. apparently in good shape except that the runner had the edges of the buckets bent by debris going through the gates. The turbine was gear-connected to a line-shaft some 15 ft. long, running at about twice the speed of the turbine, from which a 150 k.w. generator was belt-driven. The plant operated only on night load. This equipment was replaced by a single directly connected turbine and generator unit of 100 k.w. capacity, the rating of the turbine being slightly smaller than the original turbine and running at about 60% greater speed. The plant is carrying from two to four times the load previously carried, and at no time within the last two years has the plant been short of water, as had been the case each mid-summer and wid-winter season previous.

A hydro-electric plant in the central part of Michigan, drainage area 500 square miles, 14 ft. head, formerly consisted of two turbines, each one gear-connected to two short horizonal line-shafts from each of which was driven a generator. There were two outgoing feeders from the plant and the load of both feeders was sometimes carried on the larger of the two generators, and at other times the units ran separately, one to each feeder. The reconstruction here was caused by the undermining of the foundation resulting in a collapse of the power-house. The equipment of the new power-house was in two units, each consisting of a directly connected turbine and generator, the one unit being approximately one-half the capacity of the other, permitting power to be produced at high efficiency from about one-sixth to full capacity of the plant. The load on the plant has been approximately tripled since the old plant went out of service and no shortage of water has been experienced within the last two years of operation.

Increases in Power Output

A hydro-electric plant consisting of two turbines, gear-connected to a horizontal shaft about 20 ft. long, to the end of which was directly connected a horizontal shaft, slow speed generator of 350 k.w. capacity, and to which was also belted a steam engine. One turbine, the gears and part of the horizontal shaft were removed, and a vertical shaft, directly connected generator unit installed with a turbine capacity slightly larger than one of the original turbine. Upon completion of the work the load was thrown from the remaining gear-driven unit, to the new unit and 100% additional load thrown on, and after shutting down the old unit the surface of the water in the tail race dropped about 4 ins. due to the decreased discharge through the new turbine, even when carrying double load of the old one.

In an industrial plant requiring power 9 hours, three old turbines were removed and replaced by one vertical shaft turbine, gear-connected to a mill, with the turbine selected for proper speed for connection to a future alternating current, vertical shaft generator. The new unit, although slightly larger than larger turbine of the old installation, is carrying, at about two-thirds capacity, the entire mill equipment, which has been materially increased over the installation which the old turbines could just carry.

PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSURE OF TURBINE GATES*

By Minton M. Warren
Engineering Department, Stone & Webster Engineering Corporation, Boston, Mass.

MR. GIBSON'S paper goes into the mathematical theory of ordinary water hammer more thoroughly than any previous discussion of the question, and is certainly a valuable addition to the literature on this subject. The curves presented by the author show the differences in the various formulas with great clearness.

The writer, however, does not believe that Mr. Gibson's method and formulas are practical for ordinary use for three reasons:—

First.—In order to use the formula, a large amount of very tedious figuring must be done, and unless it is very carefully checked by logarithms, a very small arithmetical mistake may make a large error in the result.

Second.—The formulas have not been confirmed by experiments and are based on certain assumptions the accuracy of which are open to question.

Third.—In most cases, simpler formulas will give as accurate results as the data warrant.

It is almost impossible to get away from the idea that the more calculations and exact mathematical methods used in obtaining a result in engineering, the more accurate the result will be, regardless of the assumptions on which the calculation is based. It is the same false accuracy that leads engineers to submit cost estimates figured down to odd cents on projects running into millions.

The writer does not believe that the many assumptions needed in deducing any formula for slow-closing gates warrant the elaborate methods used by Mr. Gibson, until these methods and formulas are backed up by careful and extensive experimental data, as were the formulas of Professor Joukovsky.

In arriving at his results, Mr. Gibson assumes that the area of the gate is closed at a uniform rate, whereas the writer, in deducing his simple formula, $h = LV/g(T-L/a)$, assumed that the gate moved in such a way as to cause the pressure to rise at a constant rate. In any given case, neither assumption is strictly true, and experiment alone will show which is nearer the average gate motion.

Referring to Fig. 9†, it is seen that, according to the author's calculations, such a gate motion, giving a constant rise of pressure, is not far from a straight line, and probably as near the truth in ordinary gates as his assumption (uniform reduction of area), which makes the mathematics very much more difficult.

There is great need for a series of careful experiments on slow-closing gates, and it is to be hoped that Mr. Gibson, or some other engineer, will undertake this work. Data from such tests properly used would be of more service to the profession than the most perfect theoretical formulas which have never been tested. Until this is done, engineers will have to base design on the meagre practical data available, guiding their judgment by unproved formulas, and the writer has found that the simple formula given above comes nearer the pressures he has observed in practice than other formulas, although, like the others, it is based on certain assumptions which are not strictly true.

In one point, Mr. Gibson's formula gives what appears to the writer unreasonable results. This is illustrated in Fig. 4§, where the curve rises very sharply between heads of from 10 to 100 ft. Alliévi's curve rises even more sharply and can be easily proved wrong, as it reaches values of h which are far above the maximum value possibly reached in instantaneous closing.

Mr. Gibson's curve stops at that value, but the writer does not believe that experiments confirm the large increase in water hammer for low heads over that for high heads. His assumption that the waves are perfectly reflected from the slowly closing gate is also open to question, and was not proved in Joukovsky's experiments.

It is not intended to imply that Mr. Gibson's formulas may not prove to be as accurate or even more accurate than the others, but, in the absence of any experimental proof, their added complexity does not seem to be warranted, in view of the approximations and assumptions on which they are based.

ASSOCIATION OF C. B. & C. I. NEWS NOTES

AT the National Industrial Conference, the Association of Canadian Building and Construction Industries was represented by J. P. Anglin (Montreal), Fred Armstrong (Toronto), E. R. Reid (St. John), G. H. Whitlock (Moose Jaw), and Col. J. A. Little (Port Arthur); also by A. H. Dancy (Toronto), who substituted for H. T. Hazelton (Winnipeg). While on the way to the conference, Mr. Hazelton was taken suddenly ill, had to go to the hospital in Fort William, and later returned to his home in Winnipeg.

Mr. Armstrong was appointed a member of the committee dealing with the question of the eight-hour day, and Mr. Anglin was elected chairman of the committee dealing with the question of collective bargaining and the recognition of labor unions.

During the conference a number of the Montreal and Ottawa members of the national council met with the delegates at dinner and afterwards held an informal council meeting. J. C. Frazee, secretary of the National Federation of the United States, was present and gave an interesting address on the history and methods of his organization.

It was decided to hold the next general conference in Ottawa commencing the last week of January, 1920, general sessions to commence Tuesday, January 27th. All contractors and builders and supply men throughout Canada are invited to reserve these dates and attend.

It was also decided, at the request of the western delegates, to have a convention in the west about the end of next month or the first week in December. A number of eastern men are planning to make the trip.

Arrangements have been prefected by the Dominion Bridge Co., Ltd., Montreal, for the manufacture of machinery for the pulp and paper trade. The company intends to contract for entire plants for the manufacture of newprint. It has submitted a tender, amounting to approximately a million dollars, to one of the large paper companies in Canada to supply the latter with complete equipment and machinery for the manufacture of newsprint.

At a meeting of the Chamber of Commerce of Brantford, Ont., held last week, a resolution was adopted protesting against the decision of the provincial department of highways to lay water-bound macadam on the provincial highway between Hamilton and Brantford, and urging that a more permanent type of construction be adopted in view of the fact that the Theodore Roosevelt International Highway will be routed by that road, thus assuring a continuous and heavy traffic.

The following resolution has been drafted for presentation to the Board of Directors of the American Association of Engineers at its October meeting: "Resolved that the Board of Directors of the American Association of Engineers call a conference of representatives of all organizations or societies of engineers, architects and similarly educated or experienced technical men, for the purpose of strengthening the position of engineers and technical men as a group distinct from labor and from capital but essential to both and to society in general, because of the fact that stability of the social structure resting on the tripod of labor, capital and engineering, is dependent upon the strength of this third support."

THE NATIONAL INDUSTRIAL CONFERENCE

DISTINCTIVE among the features of the National Industrial Conference held last week was the ready agreement as to the benefits to be derived from uniformity in labor legislation, and from industrial councils at the meetings of which questions arising in any plant or in any industry could be discussed. Curiously enough, these both concern the form rather than the substance of labor adjustments, for in the case of legislation the conference did not commit itself as to what legislation should be adopted, but suggested that this should be investigated by a commission, which would use existing labor legislation as its material.

On the subject of hours of labor, most of the employers' representatives were convinced that the eight-hour day would reduce production. The labor delegates did not debate this issue, but on the other hand would not compromise it, preferring to stand by the eight-hour day as part of the program of organized labor throughout the world. The third group, as represented in the committee on the eight-hour day, passed a somewhat colorless resolution urging that it should be confirmed by legislation in those industries in which it had already been adopted. On this question, one of the principle subjects of debate at the present time, there was therefore no appreciable progress made.

Regarding the recognition of union, however, practically all employer delegates expressed themselves as not being opposed to organization, provided the employee was not forced to join the union. In reply to a question on this point, Tom Moore, president of the Trades and Labor Congress, stated that the recognition of a union did not imply the closed shop, unless this was specified in the particular agreement. There seems in fact to be no general objection to the organization of labor, provided that every employee is at full liberty to use his own discretion, and that employers are not forced to deal with organizations which extend beyond their own industry, and which can tie it up in spite of the fact that there is no disagreement at the time.

BARE vs. WEATHERPROOF WIRES

IN reply to a circular sent to central stations throughout Canada, A. A. Dion, of Ottawa, chairman of the Canadian Electrical Association's committee on overhead lines, received the following letter from one of the companies:—

"Re bare wire for line use under 2,200 volts. It has never been the practice of this company to use bare wire for city distribution and although it is generally understood that the insulation on the wire, especially after it has been baked out, is no adequate protection for 2,200 volts, it is useful in the erection of the lines so as to avoid mechanical injury and also from coming in contact with live lines already placed.

"Our company's rules provide that all lines are normally considered alive by our men and work done accordingly. Lines are only treated as dead when known to have been killed properly and the proper clearances given. In order to show differentiation between primary and secondary lines, lines of 2,000 and 4,000 volts are erected on porcelain insulators, while low voltage lines are on glass insulators.

"Use of both bare and weatherproof wire would necessitate carrying two classes of wire in stock as well as on repair and construction wagons. In city work the primary is only a small part of the distribution system and it would be still necessary to supply insulated weatherproof wire for all service work.

"In outlying districts where primary runs are long and service connections few, it would likely be considerably more feasible to use the bare wire."

Mr. Dion states as his own opinion that while ordinary weatherproof triple-braided insulation is not altogether effective, and linemen should treat all wires as alive, still the insulation is some measure of protection in dry weather and he favors its use on city streets.

ENGINEERING INSTITUTE ELECTIONS

AT a meeting of the council of the Engineering Institute of Canada, held September 23rd, 1919, in Montreal, the following elections and transfers were announced:—

Members.—W. H. Boyd, Ottawa; C. A. K. Cornwall, Victoria; David Kyle, Sault Ste. Marie.

Associate members.—H. W. Ault, Ottawa; H. E. Balfour, Quebec; J. A. Beauchemin, Ottawa; V. S. Chestnut, East St. John, N.B.; H. W. Frith, Vancouver; H. P. Fuller, St. James, Man.; L. E. Habben, Shawinigan Falls; D. W. Hodson, Nelson, B.C.; D. W. Jamieson, Ottawa; W. C. Macdonald, Woodman's Point, N.B.; J. G. MacLachlan, Kamloops; T. V. McCarthy, Toronto; J. C. McDougall, Montreal; J. F. O'Connor, Aylmer East, Que.; S. R. Parker, Regina; F. M. Perry, Sault Ste. Marie; Maurice Polet, Edmonton; C. H. Pozer, Vancouver; H. W. Racey, Westmount, Que,; A. S. Runciman, Montreal; H. B. Sherman, Regina; Sigmund Wang, Hawkesbury, Ont.; K. E. Whitman, Halifax; W. A. Winfield, Halifax; W. I. Young, St. John, N.B.

Juniors.—A. L. Bishop, St. Catharines; W. E. Plummer, St. Catharines.

Transferred associate members to members.—A. R. Archer, Port Washington, N.Y.; J. T. Farmer, Montreal; J. P. Hodgson, Vancouver.

Transferred, juniors to associate members.—J. G. Caron, Montreal; G. H. Kohl, Hamilton.

Transferred, students to associate members.—R. G. Bangs, St. Catharines; A. K. Hay, Ottawa, C. F. Szammers, Toronto; F. W. Taylor-Bailey, St. John, N.B.

Transferred, students to juniors.—Ralph Allingham, Grenville, Que.; G. H. Chalmers, Turbine, Ont.; C. H. R. Fuller, Toronto; E. C. Little, St. Catharines; J. E. Pringle, Hamilton.

Transferred, junior to associate member.—W. H. Norrish, Ottawa.

PERSONALS

WILLIAM STORRIE, who recently resigned as chief engineer and director of the John ver Mehr Engineering Co., Ltd., Toronto, in order to enter private practice, was born October 4th, 1883, in Paisley, Scotland. Mr. Storrie was educated at the Grammar School and Technical College at Paisley, and subsequently at the Glasgow and West of Scotland Technical College. He became an articled pupil to James Lee, city engineer of Paisley, and from 1899 to 1907, was engaged chiefly on water works construction. In 1902, he won the Brough scholarship and in 1905 the Glasgow Building Trades Exchange prize. In 1907, Mr. Storrie was appointed chief assistant to Crouch & Hogg and was engaged with them for the following two years on water works, bridge, canal and harbor construction. In 1909 he came to Canada and was appointed resident engineer on the construction of the slow sand filtration plant for the city of Toronto. In 1912, during the second typhoid epidemic in Ottawa, Ont., Mr. Storrie was appointed in charge of the water works of that city. A year later Mr. ver Mehr induced him to become chief engineer of the John ver Mehr Engineering Co., Ltd., in charge (jointly with Mr. Gore) of the design and construction of the drifting sand mechanical filtration plant at Toronto. During the past few years, in collaboration with Mr. Gore, Mr. Storrie also designed and constructed small filtration units for the Collingwood fisheries, the Dominion Bank building at Toronto, and the Sun Life building at Montreal. He and Mr. Gore also designed and recently completed a filtration plant of 1,728,000 Imperial gallons daily capacity for the town of Oshawa, Ont., and an effluent disposal works for the Robson tanneries at Oshawa, and also designed a small filtration plant for Rockland, Ont. Early in 1918, Mr. Storrie went to England to take charge of the construction of several reinforced concrete ships of 1,000-ton capacity, returning again to Canada in July last. Mr. Storrie is an associate member of the Institution of Civil Engineers of Great Britain and a member of the Engineering Institute of Canada. He is also a member of the American Water Works Association.

J. P. HARVEY has resumed his duties as town engineer of Vermilion, Alta., after having been overseas since August, 1914.

W. C. MILLER, assistant city engineer of St. Thomas, Ont., has been appointed city engineer, succeeding M. Ferguson, who recently resigned.

K. S. MACDONNELL, who returned from overseas two weeks ago, has resumed his work as town engineer of Barrie, Ont. Capt. Macdonnell was in the army for four years and seven months, serving twenty-seven months in France. After the armistice he was in charge of the prison camp at Abbeville, France.

D. H. WEIR has been appointed to a position on the teaching staff of the Technical School at London, Ont. Mr. Weir is a graduate of the University of Toronto, Faculty of Applied Science and Engineering, and was formerly assistant to the engineer of the counties of Dundas and Stormont, Ont. He was with the First Canadian Engineers for three years and was later appointed educational officer in connection with the Khaki University, with the first division.

PAUL E. MERCIER, consulting engineer to the Public Works Department of the city of Montreal, who recently tendered his resignation, may not leave the service of the city after all, as a new proposal has been made to him by the city commissioners and Mr. Mercier has taken it under consideration. He intends, however, to join the staff of L'Ecole Polytechnique as a professor in engineering, so even if he retains his connection with the city as consulting engineer, he will not be able to devote his whole time to the municipal work.

ROBERT B. MURDOCK, who has recently returned from military service in France, has been appointed executive engineer with the Asphalt Association of New York and Toronto. He will directly assist the secretary of the association in developing the organization and operating policy. Capt. Murdock has had an extensive experience in practical highway work, during the course of which, as resident engineer, he had charge of the construction of one of the most difficult portions of the Columbia river highway, including the famous figure "8" section at Crown Point, near Portland, Ore. Later he was appointed assistant state highway engineer of Oregon and held that office until he enlisted.

WALTER E. ROSENGARTEN has resigned as highway engineer in the United States Bureau of Public Roads, to accept the position of traffic engineer with the Asphalt Association of New York and Toronto. He will deal with the co-ordination of the design of the various highway types with the requirements of modern traffic. Since his graduation from the engineering department of the University of Pennsylvania, Mr. Rosengarten has had a combination of practical highway construction experience and research study with both the University of Pennsylvania and the U. S. Bureau of Public Roads. He was with the federal bureau about eight years, during which he spent about four years in practical highway construction, and about two and a half years in the research and testing division in connection with laboratory and field work.

OBITUARY

WM. DALE HARRIS, formerly well-known as a civil engineer, died last Sunday at his home, 263 McLaren St., Ottawa, Ont. Mr. Harris was born in England, but came to Canada at the age of twelve, graduating in 1872 with the degree of B.Sc. at the Massachusetts Institute of Technology. He was engaged upon the construction of the Brookline, Mass., water works, and later surveyed and assisted in the construction of the Intercolonial Railway, Nova Scotia Railway, Montreal and Western Railway and Gatineau Valley Railway. After having served five years as president of the Montreal Terminal Railway, he retired in 1901, although for the following few years he engaged in a certain amount of private practice.

Gore, Nasmith & Storrie, consulting engineers, have obtained offices at 409 Confederation Life Building, Toronto. This firm was recently organized with the intention of specializing in public health engineering.

The Public Utilities Commission of Manitoba has granted permission to the city of Brandon to increase its water rates by 20%. At a consultation between the commission and members of the city council, it was pointed out by Geo. L. Guy, engineer of the commission, that the city is losing considerable money on the water works, and that he would support the application for increase in rates. Mr. Guy also stated that there is considerable leakage in the Brandon water works system. It is understood that the increase in rates is to relieve the city temporarily, in a financial way, pending the completion of an exhaustive survey of the entire system.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Brantford, Ont.—City council contemplates construction of a bridge. T. H. Jones, city engineer.

Battleford, Sask.—The highway department, province of Saskatchewan, will soon award contract for improvement of road between Battleford and North Battleford. Length, 8,000 lin. ft. Fill required, 2,500 cu. yds. clay, and 2,000 cu. yds. gravel. H. S. Carpenter, deputy minister, Regina, Sask.

Brockville, Ont.—The Dominion government is constructing a new timber bridge on concrete piers over the Rideau River at Sly's Rapids.

East Kildonan, Man.—Contracts will soon be awarded by council, for construction of concrete sidewalks on Ottawa Ave. H. Thompson, secretary-treasurer.

Ford City, Ont.—Council will construct Silex walks on Ottawa St. n. side, Strabane to end of Ottawa St. and on Sandwich St., s.s., from lot No. 106 easterly to lot No. 3. J. E. Foster, clerk.

Galt, Ont.—Council will construct bituminous macadam pavement, with concrete curbs and gutter, on Queen St. W., from G.T. Ry. to Blair Rd. Estimated cost, $4,679. Asphaltic concrete pavement, with concrete curbs and gutter, on Queen St. W., from w.s. of West Main St. to the G.T. Ry. Estimated cost, $3,833. J. McCartney, clerk.

Gananoque, Ont.—Tenders will be received until 12 o'clock noon, October 14th, by the Ontario department of highways for construction of concrete structures on the provincial highway, in the township of Pittsburgh. Plans, etc., office of resident engineer, Gananoque; city engineer, Kingston, and at the department in Toronto. W. A. McLean, deputy minister.

Hespeler, Ont.—By-law has been passed by town council providing for expropriation of land on the Goebel estate to widen the corner of Guelph and Queen St.

London, Ont.—The London and Port Stanley Railway Commission will repair bridge over the Kettle creek, $11,000; construct a coal-ferry slip at Port Stanley, $8,500; erect loading platforms and shelters along the road, $6,500; overhead bridge repairs at Mohawk St., St. Thomas, $5,700; additions to sidings and double tracking line in St. Thomas, $25,000; additional electric locomotives and rolling stock. Total estimated expenditure, $370,000. Immediate expenditure necessary, $200,000. J. E. Richards, manager of radial. Sir Adam Beck, chairman of commission.

Niagara Falls, Ont.—City council will shortly call for tenders for construction of asphalt pavement with Willite process on Palmer Ave., between Benson and Victoria Ave Estimated cost, $42,353; and on Kitchener St., between Victoria and Powell Ave. Estimated cost, $17,744.85. W. J Seymour, city clerk.

North Vancouver, B.C.—The department of public works, Victoria, B.C., will soon demolish the Moodyville trestle bridge. A. E. Foreman, engineer.

North Vancouver, B.C.—The district council has decided to proceed with necessary repairs to the Capilano Marine Drive bridge. Estimated cost, $1,500. Engineer Cosgrove.

Pembroke, Ont.—Town council contemplates widening stone bridge on Pembroke St., and construction of 6 ft. sidewalks. A. J. Fortier, town clerk.

Peterborough, Ont.—City council has decided to open Cambridge St., north of McDonnel St., and to widen McDonnel St., west of the bridge over the creek.

Peterborough, Ont.—Council has decided to construct asphaltic concrete pavement on George St., from the C.P. Ry. to Romaine St., early next year.

Pickering, Ont.—Contract has been awarded by the Ontario department of highways for construction of the superstructure of bridge to J. McGinnity, Pickering. W. A. McLean, deputy minister.

Port Credit, Ont.—The Hamilton Highway Commission contemplate construction of an additional bridge over an arm of the Credit River, 200 yds. from the present bridge.

Prescott, Ont.—Tenders will be received by the highway department, province of Ontario, until noon, October 6th, for supplying field stone in piles along the provincial highway, from Prescott to Cornwall. W. A. McLean, deputy minister.

Sandwich, Ont.—Town council has ordered starting of construction of paving on Prince Rd., to be completed before October 23rd.

St. Jean, Que.—City council will soon commence construction of sidewalks for which tenders were called to be in by September 29th. H. Morais, secretary-treasurer.

Ste. Anne-de-Chicoutimi, P.Q.—Contract for the construction of the St. Maurice Rd. has been awarded to D. De Santis, 3180 St. Lawrence Blvd., Montreal.

St. John, N.B.—The city council has received the following recommended program of road construction to cover a period of four years: Douglas Ave., asphalt, granite blocks on concrete base in car tracks, $163,380; City Rd., Pond St. to Marsh Bridge, granite blocks, $134,740; Haymarket Sq., west side, asphalt, $6,058; Haymarket Sq., south side, from Brussels St. to Marsh Bridge, asphalt, $25,649; Marsh Rd., from bridge to city limits, asphalt, $109,890; Brussels St., asphalt, $86,175; Prince William St., from Princess to St. James St., asphalt, $41,011; Market Sq., asphalt and granite blocks, $36,212; St. James St., from Prince William to Wentworth St., asphalt, $57,151; Britain St., from Reed's Pt. to Charlotte St., granite blocks, $30,552; Waterloo St., from Union to Golding St., asphalt, $37,880. Estimated total cost, $728,698. G. N. Hatfield, city engineer.

St. Thomas, Ont.—One tender was received for construction of pavement on Hemlock St. Contractor, W. Irwin, for water-bound macadam, $2,875.60. Contract was not awarded, as council preferred, upon recommendation of W. C. Miller, city engineer, to construct an asphaltic macadam pavement on this street. New tenders will probably be called in a short time for this type of construction.

Toronto, Ont.—Board of control will call tenders for construction of pavement on St. Clair Ave. from the end of the existing pavement to Keele St.

Toronto, Ont.—Department of works contemplates repairs to subway under the C.P. Ry. at Runnymede Rd. R C. Harris, commissioner.

Toronto, Ont.—The city department of works has commenced filling the ravine on Gerrard St., east of Leslie St. Earth for this fill is being hauled from the east side of Coxwell Ave., by the city narrow-gauge construction railway.

Toronto, Ont.—Additional tenders received by the Board of Control for construction of pavements, contracts for which have been awarded, and details of which appear on the next page, were as follows: From the Godson Contracting Co., Ltd., asphalt, Annette St., Keele to High Park Ave., $15,894; Annette St., High Park Ave. to Fairview Ave., $28,138; Kenilworth Ave., Queen St. to 200 ft. n., $3,165; Middleton St., Sheridan to Brock Ave., $4,046. From Constructing and Paving Co., Ltd., asphalt, Fernwood Park Ave., Fir to Hazel Ave., $4,028; Fernwood Park Ave., Fir to 306 ft. s.,

$3,994; Front St., Spadina to John St., $26,876; Kenilworth Ave., Queen St. to 200 ft. n., $3,221; Kenilworth Ave., 200 ft. n. of Queen St. to 1,228 ft. s. of Kingston Rd., $15,575; Logan Ave., G.T. Ry. to Gerrard St., $9,685; McLean Ave., Queen St. to s. end, $17,140. From the Department of works, asphalt, Annette St., Keele to High Park Ave., $16,216; Annette St., High Park Ave. to Fairview Ave., $28,844; Fernwood Park Ave., from Fir to Hazel Ave., $3,959; Fernwood Park Ave., Fir to 306 ft. s., $4,064; Front St., Spadina to John St., $26,865; Kenilworth Ave., 200 ft. n. of Queen St. to 1,228 ft. s. Kingston Rd., $15,601; Logan Ave., G.T. Ry. to Gerrard St., $9,500; Middleton Ave., Sheridan to Brock Ave., $4,048; McLean Ave., Queen St. to s. end, $17,081. Brick block pavement on Waverley Rd., from Godson Contracting Co., Ltd., $19,844; and Department of Works, $21,146. R. C. Harris, commissioner of works.

Toronto, Ont.—Contracts have been awarded by the Board of Control for construction of pavements on the following streets: Bitulithic on Northcliffe Blvd., from Regal Rd. to St. Clair Ave.; Rosemount Ave., from Glenholme Ave. to Northcliffe Blvd.; Springmount Ave., from Oakwood Ave to n. limit, lot No. 30, plan M-312, to the Warren Bituminous Paving Co., Ltd., Toronto. Brick block pavement on Waverley Rd., from 1,300 ft. n. of Queen St. to Kingston Rd., to Asphaltic Concrete Co., Ltd., $19,824. Rejected tenders, Godson Contracting Co., Ltd., $19,844; Department of Works, $21,146. Concrete pavements on Belsize Dr., Yonge St. to Mt. Pleasant Rd., $16,044; Manor Rd., Yonge St. to Oswald Cres., $7,378; Sheldrake Ave., w.s.l., Sheldrake Blvd. to Beulah St., $5,583; Sheldrake Blvd., Yonge St. to Sheldrake Ave., $12,934, to the Department of Works. No other tenders were received. Asphalt pavements to Constructing and Paving Co., Ltd., Annette St., Keele St. to High Park Ave., $15,648; Annette St., High Park Ave. to Fairview Ave., $27,670; Middleton St., Sheridan Ave. to Brock Ave., $4,004. Asphalt pavement to Godson Contracting Co., Ltd., Fernwood Park Ave., Fir Ave. to Hazel Ave., $3,937; Fernwood Park Ave., Fir Ave. to 306 ft. s., $3,912; Front St., John St. to Spadina Ave., $25,877; Kenilworth Ave., 200 ft. w. of Queen St. to 1,228 ft. s. of Kingston Rd., $15,213; Logan Ave., G.T. Ry. to Gerrard St., $9,438; McLean Ave., Queen St. to s. end, $16,796. Asphalt pavements to the Department of Works, Kenilworth Ave., from Queen St. to 200 ft. n., $3,157. Concrete curbing to Godson Contracting Co., Ltd., Front St., n.s., John St. to Spadina Ave., 80c. per lin. ft. Concrete curbing to Constructing and Paving Co., Ltd., Annette St., s.s., Keele St. to Aziel St., 73c. per lin. ft.; Middleton St., n.s., Sheridan Ave. to Brock Ave., 73c. per lin. ft. Concrete curbing to Asphaltic Concrete Co., Ltd., Waverley Rd., w.s., 165 ft. 8 in., and e.s., 171 ft., 80c. per lin. ft. R. C. Harris, commissioner of works.

Vancouver, B.C.—Council has requested estimates for sidewalk on Bellevue at Twenty-Seventh St., and for opening a new roadway on King St. off Twenty-Third St. This new roadway is necessary in connection with construction of factory about to be undertaken by W. H. Todd and C. G. Barrow. Engineer Bell.

Walkerville, Ont.—Town council will construct concrete pavement on Dacotah and Oneida Sts. A. C. Cock, clerk.

Windsor, Ont.—City engineer will start construction of pavement on London St., Ouellette Ave. to Windsor Ave., immediately. Time of completion, October 23rd. E. Brian, city engineer.

Winnipeg, Man.—The repairs to the Redwood bridge will be completed and the bridge opened for traffic within three weeks. W. P. Brereton, city engineer.

Winnipeg, Man.—By-law will be prepared providing for construction of a new bridge on Maryland St. Estimated cost, $500,000. W. P. Brereton, city engineer.

Winnipeg, Man.—Tenders will be received until 12 o'clock noon, October 7th, by the C.N. Ry. for construction of Athabasca St. subway. H. A. Dixon, chief engineer.

Winnipeg, Man.—City council contemplates construction of a pavement on Newman St., and favors the removal of car tracks from River St., which will be paved as a residential thoroughfare. W. P. Brereton, city engineer.

York Township, Ont.—Contracts have been awarded by township council, for construction of concrete sidewalks as follows: To Walton and Rowell, Atlas Ave., 4 ft. 6 ins., $4,375; St. John's Rd, 5 ft., $4,600; St. Clair Ave., n.s., 5 ft., city limit to Jane St., $4,500. To Angotti and Smythe, Dennis Ave., s.s., 1,067 lin. ft., $2,875; Medway Ave., 234 lin. ft., $775; Frejama Ave., from Lambton to Cæsar, 1,218 lin. ft., $3,200. Frank Barber, engineer.

York Tp., Ont.—Tenders will be received until 12 o'clock noon, October 6th, by township council for construction of concrete sidewalks on Brownhill Ave., Eversfield Ave., Keene St., Lauder Ave., Glenholme Ave., Barr Ave., Pape Ave. and Weston Rd. Engineer, Frank Barber, 40 Jarvis St., Toronto.

WATER, SEWAGE AND REFUSE

Agassiz, B.C.—By-law has been passed by the Kent municipal council providing for the following works in draining 1,280 acres on Hammersley prairie: Earth fill, $1,200; installation of a concrete culvert and sluice gate; clearing and resurfacing of the old dam; removal of present pumping station and erection in a more suitable site. Total cost, $4,800. Engineer, Frank Sweatman.

Brandon, Man.—The Public Utilities Commission will undertake an exhaustive survey of the waterworks system to detect large leakages and to plan for enlargements.

Dundas, Ont.—F. F. Fry, of Toronto, who has the contract for installation of sewers, will have completed most of the work before winter. The sewer which commences at King and York St. and runs along York St. to the town hall will be constructed partly in tunnel.

East Kildonan, Man.—Contracts will soon be awarded for supply of piping, valves, hydrants and fittings; construction of sewers on Munroe and Watt St.; construction of water mains on East Kildonan Rd., Helmsdale Ave. and Oakview Ave. H. Thompson, secretary-treasurer.

East Kildonan, Man.—Council will construct sewers on Watt St., from Munroe Ave. to city limit; Munroe Ave., from Roch St. to Watt St. Water mains on East Kildonan Rd., from Trent Ave. to Leighton Ave.; Helmsdale Ave., from East Kildonan Rd. to Kildonan Dr.; Oakview Ave., from lane west of East Kildonan Rd. to East Kildonan Rd. H. Thompson, secretary-treasurer.

Eriksdale, Man.—Tenders will be received until 12 o'clock noon, October 3rd, by the municipal council for drilling drainage wells as follows; North of section 35-21-5 w., north of section 33-21-5 w., n.e. corner section 33-21-6 w., n.w. corner section 33-21-6 w. J. Sharpe, secretary-treasurer.

Fort William, Ont.—Board of works has recommended construction of sewers on Luci Court.

Galt, Ont.—City council will construct sewer and storm drain on Borden St., from First Ave. to Stanley St.; Stanley St., from Borden St. to Tait St.; Tait St., from Stanley St. to Francis St. Estimated cost, $3,006.89. J. McCartney, clerk.

Kirkfield Park, Man.—Contracts will soon be awarded by the council of the rural municipality of Assiniboia, for construction of a sewer and laying of water mains on Kensington, King Edward, Oakdale Place, Sutherland and Munroe Streets, also for supply of cast-iron pipes, hydrants and valves. Frank Ness, secretary-treasurer.

Medicine Hat, Alta.—City council has requested city engineer to prepare a report on construction of water mains throughout the Purmal subdivision.

London, Ont.—The Public Utilities Commission have three plans for conservation of domestic water: (1) Installation of meters on all services; (2) construction of an additional reservoir at Springbank; (3) supply the G.T. Ry. and as many other large consumers as possible with river water. Two pumps will be in operation, supplying river water in a short time. Meters are being placed on new services. A report will be submitted to the commission in reference to

20-Year Barrett Specification Roof on Hog Pens of Union Stock Yards, Ltd., Toronto, Canada. Architects: Union Stock Yards, Ltd. General Contractors: Archibald & Holmes, Toronto, Can. Roofers: The Maitland Roofing & Supply Co., McDermid Bros. Successors, Toronto, Can.

100,000 Square Feet of Barrett Specification Roofs

The above photograph shows the mammoth new Hog Pens of the Union Stock Yards, Ltd., Toronto, in process of construction.

This is a roofing job of more than one hundred thousand square feet, covering one continuous building, extending back beyond the sixth monitor in the picture.

Naturally, in deciding what type of roof to adopt for this enormous plant, the question of cost had to be given careful consideration.

It is significant, therefore, that a Barrett Specification Roof should have been decided on.

It means that the Union Stock Yards architects fully realize what so many architects and builders have come to appreciate—that it *pays* to buy the *best* roof because, while the original cost may be a little higher, *the cost per year of service is lower than for any other type.*

This plant has a roof that will stand up year after year under the rigorous Canadian climate; one that takes the base rate of insurance and that is guaranteed for 20 years.

Guaranteed for 20 Years

So sure are we of the service Barrett Specification Roofs will give *under the most severe conditions* that we are prepared to *guarantee them for 20 years*, in all towns of 25,000 or over, and in smaller places where our Inspection Service is available, provided they are 50 squares or more in area. The guaranty costs you nothing. We merely require that our Specification dated May 1, 1916, shall be strictly followed and that the roofing contractor be approved by us. The guaranty is a Surety Bond issued by a well-known fidelity and guaranty company.

A copy of The Barrett 20-Year Specification, with roofing diagrams, sent free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST JOHN N.B. HALIFAX, N.S SYDNEY, N S.

cost and location of the proposed new reservoir. E. V. Buchanan, waterworks manager. H. A. Brazier, city engineer.

Maidstone, Ont.—Tenders will be received until October 11th by the council of Sandwich South township for repair of the Oldcastle drain. J. McAuliffe, clerk.

North Bay, Ont.—By-law has been passed by town council providing for improving, extending, altering and enlarging existing sanitary sewerage system on part of Worthington and Sherbrooke St. Estimated cost, $25,640.75. M. W. Flannery, clerk.

North Vancouver, B.C.—Extensive improvements are contemplated by the district council to be undertaken early in the next year. It is proposed to either enlarge the present dam at the Mosquito waterworks intake, supplying water to the North Lonsdale district, or construct an additional dam.

Pembroke, Ont.—Contract has been awarded by town council for construction of storm sewers on Forced Rd., Government Rd., Somerset St. and Christie St., to Behan and Leeney. A. J. Fortier, town clerk.

Peterborough, Ont.—E. A. Peck, solicitor for the corporations and boards of health of the municipalities of Otanabee, North and South Monaghan, has submitted an application to the Ontario Municipal Board, asking for an order to restrain the city of Peterborough, from emptying sewage into the river and to compel council to purchase a site for the erection of sewage disposal plant.

St. Jean, Que.—City council will proceed to construct water mains on Richelieu St., between Lemoine and St. Charles St., and a sewer on Jacques Cartier St., between the C.P. Ry. and St. Paul St. H. Morais, secretary-treasurer.

St. John, N.B.—City council contemplates construction of a sewer on Protection St. G. N. Hatfield, city engineer.

Toronto, Ont.—The board of control has recommended the construction of the following water main extensions: Durie St., 6 ins., 280 ft.; Webb Ave., 6 ins., 480 ft.; Bastedo Ave., 6 ins., 470 ft.; Evans Ave., 6 ins., 280 ft.; Evans Ave., 6 ins., 400 ft.; Cleveland St., 6 ins., 580 ft.; Cluny Dr., 6 ins., 545 ft.; Windermere Ave., 6 ins., 336 ft. Estimated cost, $8,904.59.

Toronto, Ont.—Contracts have been awarded by the board of control for construction of sewers as follows: College St., Beatrice St. to Palmerston Ave., brick, $31 per lin. ft. and College St., from Palmerston Ave to Spadina Ave., brick, $21.61 per lin. ft., to the Connolly-Agnew Construction Co. Hastings Ave., Queen St. and Leslie St., to 700 ft. n. of Queen St.; Coady Ave., Queen St., to 700 ft. n. and Eaton Ave., Danforth Ave., to 500 ft. n., will be costructed by day labor under direction of the department of works.

Walkerville, Ont.—City council will construct a 10-in. crock sewer in the alley between Dacotah and Oneida Sts. and in alley between Oneida and Seminole St. A. E. Cock, clerk.

Walkerville, Ont.—The Walkerville Water Co. has under construction the following water mains: 15,146 lin. ft. of 6-in. pipe, 3,140 lin. ft. of 8-in. pipe, 3,000 lin. ft. of 10-in. pipe and 2,400 lin. ft. of 12-in. pipe. C. D. Brown, secretary-treasurer.

Winnipeg, Man.—The commissioners of the Greater Winnipeg Water District have received tenders and will soon award contract for supply and construction of a water line between the 66-in. pipe line of the water district and the municipal reservoir at the town of Transcona. R. D. Waugh, chairman.

Woodstock, Ont.—Ure and Son, consulting engineers for the city of Woodstock on sewage disposal, have recommended against the activated sludge process on account of the cost and are investigating another system at present in operation in Toronto, Ont. Plans are being prepared along the latter lines and will soon be submitted to council.

York Township, Ont.—The Trust and Guarantee Co., on behalf of the Robert Davies estate, have applied to council for construction of water mains on Thorncliffe Bvd., from Chester Hill Bvd. to Cambridge Ave., and on Chester Hill Bvd., from Don Mills Rd. to the Davies property.

York Township, Ont.—Ratepayers of Todmorden and North Danforth districts, York township, are considering obtaining a supply of water either through the proposed new Scarboro system, or by construction of an independent plant.

LIGHT, HEAT AND POWER

Bedford, Que.—Town council passed by-law authorizing purchase of the Bedford Light Co.'s electric plant and water system. W. Giroux, mayor.

Chatham, Ont.—The public utilities commission have purchased the electrical business of the Chatham Gas Co. Cost, $2,000 per year for 20 years without interest, and 1917 scrap value for all equipment.

Edmonton, Alta.—City council has taken over the local power plant, the owners having refused to operate in consequence of the rejection of a request for increased rates by the Public Utilities Commission.

Edmonton, Alta.—The Edmonton city council is to be asked to join with other municipalities in urging the Alberta government to look into the hydro-electric possibilities of the province, with the object of establishing public-owned generating stations similar to the system in Ontario. The following locations are mentioned as possible sources of power: Athabasca River, 250 mls. n. of Edmonton, 170,000 horse-power; Red Deer River, at Red Deer, 7,000 horse-power; Bow River, Calgary, 48,000 horse-power; Saskatchewan River, 65 mls. w. of Edmonton, 50,000 horse-power.

Lakefield, Ont.—The Hydro-Electric Power Commission will immediately construct a transmission line, from dam No. 5, to supply all necessary power for Lakefield. Sir Adam Beck, chairman.

Pembroke, Ont.—Town council has prepared agreement with the Pembroke Electric Light Co. for a new street lighting system and for removal of company poles from Main St. A. J. Fortier, town clerk.

Peterborough, Ont.—The new transmission line being constructed from Healey Falls to Peterborough, will also provide power for Norwood, Havelock and the surrounding township.

Sault Ste. Marie, Ont.—Lake Superior Power Corporation are contemplating additions to hydro-electric power plant to supply the Algoma Steel Co. with additional power in case the latter company adopts the present plans for extensions to steel plant. A. E. Pickering, manager of power company, is investigating various makes of water turbines and electrical equipment.

York Township, Ont.—Application has been made to council by the Trust and Guarantee Co., on behalf of the Robert Davies estate, for construction of electric lighting system on Thorncliffe and Chester Hill Blvd.

York Township, Ont.—The Toronto Hydro-Electric system will construct lighting systems on Jane St., East Dr., Bexley, Pendeen, Sibley and Walnut Avenues, Divers St., Roach Ave. north of Alice St., Greenwood, Mortimer and Cosborn districts and Montye Ave.

York Township, Ont.—Council contemplates construction of hydro-electric lighting systems on the following streets: Atlas Ave. to north end; Arlington Ave. to Normanna Ave.; Mulberry Ave., from Atlas to Vaughan Rd.; Holland Park Ave., from Mulberry Ave. to Oakwood Ave.; Barrie Avė., from Atlas to west end; Watford St., from Atlas Ave. to west end.

RAILWAYS

Edmonton, Alta.—The department of railways and canals will shortly lay steel on additional mileage on the Blindman Valley Railway. It is understood that the C.P. Ry. contemplate purchase of this railway.

Fort William, Ont.—The Utilities committee has recommended the purchase of interlocking and derail switches for use on the street railway system. Estimated cost, $1,900.

Guelph, Ont.—Engineers from the Hydro-Electric Power Commission are going over the property of the Guelph Radial Ry. and will report on the cost required to place the railway in good condition.

Kitchener, Ont.—The special committee of the council and light commission, appointed to report on the Waterloo-Wellington railway has recommended that the railway be purchased by the city, provided a satisfactory price, based on the earning power of the road, can be agreed upon.

London, Ont.—The London Railway Commission will request city council to issue debentures to raise at least $200,000 for improvements to the London and Port Stanley Ry. This by-law will probably be voted upon next January. J. E. Richards, manager.

Ottawa, Ont.—City council will have plans prepared for construction of extensions to the Ottawa Electric Railway Co., when that company's franchise expires, and the railway is taken over by the city in June, 1923. Alderman Ford.

Saskatoon, Sask.—The C.P. Ry. will construct a branch line, from Saskatoon to Milden, connecting with the Bassano line somewhere near Empress. W. R. MacInnis, vice-president, C.P. Ry.

Sunny Brae, N.S.—Petitions, requesting the Dominion government to construct a railway from Sunny Brae to Guysboro and thence to Mulgrave, are being prepared. Estimated distance, 93 mls.

Toronto, Ont.—City council has passed a by-law providing for extension of the Bloor St. civic car line to Runnymede Rd. Cost, $160,000.

Toronto, Ont.—The Ontario Railway Board has approved plans for the Mount Pleasant civic car line. Tenders will be called by the city council immediately.

Toronto, Ont.—It is announced that the Hydro-radials will be equipped with standard steel sleeping cars of the same size as the steam railway pullman cars.

Toronto, Ont.—By a vote of 17 to 3, the city council decided to assume its share of the 10 per cent. guarantee in connection with the construction of the western hydro-radials.

Toronto, Ont.—It is expected that the ratepayers will vote on a by-law providing for construction of the Hydro radial from Toronto easterly toward Bowmanville next January. Estimated amount of by-law, $4,000,000.

Toronto, Ont.—The proposed eastern Hydro-radials will enter Toronto by a north and south line in the vicinity of Morley Ave. It will subway at Danforth Ave., and elevate at Queen St. It is expected that should the Hydro Commission purchase the Metropolitan radial on Yonge St., this proposed north and south line will accommodate both systems.

Winnipeg, Man.—The commissioners of the Greater Winnipeg Water District are endeavoring to obtain a grant from the Dominion government for their railroad, which is developing a large section of the province of Manitoba. R. D. Waugh, Winnipeg.

FACTORIES AND LARGE BUILDINGS

Barrie, Ont.—Town council has passed a by-law providing for alterations and additions to West Ward school, and for improvements to the South Ward school. Estimated cost, $77,000. A. W. Smith, clerk.

Brockville, Ont.—By a vote of 877 to 1, the by-law providing a free site for the proposed factory for the Brockville Paper Manufacturing Co. was passed by the ratepayers. Construction of factory will proceed immediately.

Carleton Place, Ont.—Tenders will be received until October 6th, for additions and alterations to Central School. Separate tenders will be received for heating and plumbing. Architect, J. L. Kingston, 310 Booth Building, Ottawa.

Ford City, Ont.—Contract has been awarded by A. Smith, D. M. Ferry Seed Co., for construction of a dwelling, to W. N. McEachran Sons, Ltd., Toronto. Contract price, $10,000.

Fredericton, N.B.—The John Palmer Co., Ltd., are constructing a brick addition to their factory on Argyle St. Additional floor space, 15,000 sq. ft. Contractor, John C. Smith. Contract price, $25,000.

Guelph, Ont.—The Guelph Chamber of Commerce will apply to legislature for incorporation of a company to be known as the Guelph Arena Co., Ltd., $50,000. Enclosed skating rink to be constructed on Cambridge St. Building to be two-story, seating capacity, 1,800, ice surface, 80 by 180 ft., and to have a rest room, 32 by 84 ft. Provisional directors, J. M. Taylor, F. E. Partridge, H. Quarmby, W. A. Mahoney, E. Macdonald.

Halifax, N.S.—Tenders will be received by the department of public works, Ottawa, until 12 o'clock noon, October 8th, for construction of a garage at the Bellevue Military Hospital, Halifax. Plans, etc., office of chief architect, Ottawa, superintendent of military hospitals, Halifax, and superintendent of Dominion Buildings, Halifax. R. C. Desrochers, secretary.

Hamilton, Ont.—H. Hazel will erect a brick apartment house at the corner of Caroline and Bold St. Estimated cost, $17,000.

Hamilton, Ont.—The International Plow Co. are constructing additions to buildings. Estimated cost, $200,000. A. C. Dann, superintendent.

Hamilton, Ont.—The Dominion Canners will erect a modern plant in the industrial section near the Hamilton Bridge Co. Estimated cost, $1,000,000.

Hanover, Ont.—Ratepayers will be asked to vote on by-law granting loan of $30,000 for reconstruction of flour mill, recently destroyed by fire. Owner, E. Knechtel. A second by-law will provide $10,000 for building of a park.

Ingersoll, Ont.—A by-law providing for construction of a sixteen-roomed central school, will be voted on by the ratepayers on October 17th.

Kenora, Ont.—The Kenora Rink Co. will be incorporated and construction of a new rink building will be commenced immediately. Estimated cost, $23,500.

Keremeos, B.C.—Tenders will be received until 12 o'clock noon, October 4th, by the department of public works, Victoria, for construction of school addition. Plans, etc., office of J. Mahony, Court House, Vancouver, H. Hunter, Princeton and W. G. Mattice, Keremeos. A. E. Foreman, engineer, Victoria.

Kitchener, Ont.—City council will raise funds to provide for construction of an additional water gas plant, which will double the present gas capacity. Estimated cost of construction, $50,000. G. Lippert, chairman of light commission.

London, Ont.—The board of education will have plans prepared for construction of a new collegiate institute to be built in East London. City council for 1920 will be asked to prepare by-law amounting to $250,000.

Mimico, Ont.—Tenders will be received until 2 p.m., October 8th, by the Mimico Housing Commission, for construction of twenty-two brick or tile, six-room, detached and semi-detached houses. Architect, H. R. Watson, 907 Excelsior Life Building, Toronto.

Moncton, N.B.—Jones and Davis, of St. John, N.B., will erect a factory for their new pork packing business.

New Glasgow, N.S.—The C.N. Ry. is preparing for construction of extensions and alterations to the station building at New Glasgow. F. R. Brady, general manager, eastern lines, Moncton, N.B.

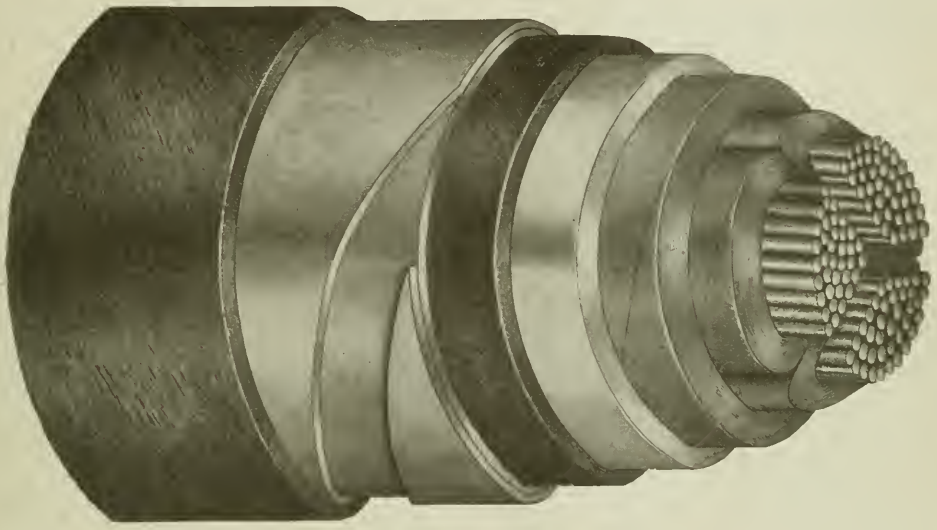
Niagara Falls, Ont.—It is announced that contracts have been awarded for construction of a big steel plant to be located between the M.C. Ry. and Chippawa creek. C. Phillips, St. Catharines, resident engineer on construction.

Ojibway, Ont.—The Canadian Steel Corporation plan construction of mills on an extensive scale. Many improvements will also be constructed throughout the town. Estimated cost, $75,000,000.

Portage la Prairie, Man.—It is expected that an additional oatmeal mill will be erected in the near future.

Portage la Prairie, Man.—The Portage school board contemplates the construction of a new four-room school building to be built in the central grounds this fall.

PAPER INSULATED CABLES



The above is a full-size illustration of a 350,000 C.M. 3-conductor 12,000 volt Paper-insulated Lead-covered Steel Tape Armoured Cable. Overall diameter 3.62 inches. Manufactured by us to the Specifications of the Hydro-Electric Power Commission of Ontario.

Eugene F. Phillips Electrical Works, Limited

Head Office and Factory: MONTREAL

Branches: Toronto Winnipeg Regina Calgary Vancouver

Port Colborne, Ont.—The government elevator will be rebuilt as soon as the wrecking operations under way are completed. The Dominion Bridge Co. have the wrecking contract.

Quebec, Que.—J. Ritchie Co., Ltd., will erect a modern factory building on Ste. Helene St. Estimated cost, $32,000.

Regina, Sask.—H. G. Smith and Co., will erect a warehouse building. Storey and Van Egmond, architects.

Rouleau, Sask.—Plans have been prepared for construction of a skating and curling rink. Architects, Storey and Van Egmond, Regina.

Saskatoon, Sask.—Construction has commenced on the new C.N. Ry. depot freight and office building. Estimated cost, $75,000. J. A. Simmons, contractor.

Saskatoon, Sask.—The Adams Harness Manufacturing Co., Ltd., contemplates erection of warehouse on First Ave. C. M. Adams, Toronto.

Tate, Sask.—Tenders will be received until 12 o'clock noon, October 4th, by the school board for construction of a school building. G. W. Hager, secretary-treasurer.

Toronto, Ont.—The property committee, city of Toronto, will call tenders for construction of a new roof for the city hall.

Toronto, Ont.—A brick and stone church will be constructed on Eversfield Rd., Earlscourt district. Seating capacity, 400.

Winnipeg, Man.—Tenders will be received until 3 p.m., October 15th, by the city council for alterations and repairs to the city pound building on Logan Ave. West. C. J. Brown, city clerk.

Winnipeg, Man.—City council has passed by-law to provide for borrowing $1,000,000 from the province to be loaned to citizens for construction of houses. It is expected that some of these houses will be erected this fall.

Winnipeg, Man.—The works committee has been requested by A. L. Cuffe, representing more than 100 airmen, to establish an airdrome. Possible sites mentioned: Eaton's playground, Norwood golf course, East Kildonan park and the exhibition grounds.

Woodstock, Ont.—The Bean and Westlake Co. contemplates a further enlargement to their plant on Brock St.

York Township, Ont.—Tenders will be received until October 9th, for an eight-room addition to Secord Ave. public school, No. 26, as follows: Reinforced concrete, brick work, hollow tile, terrazzo floors, steel casement sash, carpentry work, electrical work, plastering and painting. S. B. Coon and Son, architects, 810 Excelsior Life Building, Toronto.

MISCELLANEOUS

Cardston, Alta.—Tenders will be received until October 13th, for alterations to building and installation of hot water heating plant in the hospital at Cardston, Alta. Architects, H. M. and W. A. Whiddington, Lethbridge, Alta. H. E. Kelly, secretary-treasurer, Cardston Municipal Hospital District No. 5, Spring Coulee, Alta.

Dundas, Ont.—Two proposals for a soldiers' memorial have been made. The first took the form of a hospital, while the second, which seems to be in greater favor, calls for a monument with inscribed tablets, to be erected on the market square.

Ingersoll, Ont.—Plans have been prepared for construction of a memorial entrance to Central Park. Estimated cost, $4,000. F. H. Leake, secretary, Horticultural society.

London, Ont.—Contract has been awarded by city council for supply of pump to Goldie and McCulloch. Contract price, $1,470. H. A. Brazier, city engineer.

Montreal, Que.—Announcement has been made by the Dominion Bridge Co., Ltd., that they will equip entire plants for manufacture of intricate machinery for the pulp and paper manufacturers.

Nanaimo, B.C.—The C.P.R. will install a freight handler and make other improvements in connection with their wharf. Estimated cost, $20,000.

Ogden, Alta.—The department of natural resources, C.P.R., have called tenders for excavation of approximately 17,000 cu. yds. earth near Ogden, Alta. A. S. Dawson, chief engineer.

Pembroke, Ont.—Town council has awarded contracts as follows: Cast-iron pipe and special to National Iron Works, Ltd., Toronto; rejected tenders from Stewart and Bowden, Canada Iron Foundries, Ltd., and Dunlop and Co. Valves and hydrants for mains on Allister and Isabella Streets, to Dunlop and Co.; rejected tender from Stewart and Bowden. Sewer pipe and specials, to Dunlop and Co.; rejected tender, Stewart and Bowden. A. J. Fortier, town clerk.

Peterborough, Ont.—The foundation for the Hunter St. bridge pier, second from the river, will be constructed 3 ft. below top of hard clay, which extends another 5 ft. to solid rock, according to report submitted to council by H. W. Middlemist, engineer, Ontario Municipal Board. Frank Barber, consulting engineer, Toronto.

Port Arthur, Ont.—The Lighthouse board of the department of marine and fisheries has recommended construction of a light and fog alarm station at Angus Island. Estimated cost, $50,000. F. H. Keefer, Port Arthur.

Saskatoon, Sask.—The North Star Oil Co., have announced their intention of locating a mixing and distributing plant at Saskatoon.

St. Catharines, Ont.—A by-law to provide funds for purchase of about 10 acres of land in the north-western part of the city to be used as an athletic park, will be submitted to the ratepayers for approval next January.

St. Catharines, Ont.—An additional appropriation of $750,000 for construction work on the Welland canal has been assured by Hon. J. D. Reid, minister of railways and canals, Ottawa. James Marsh, vice-president of the labor federation.

St. John, N.B.—City council contemplates repairs to the ferry docks. Estimated cost, $8,000. G. N. Hatfield, city engineer.

St. John, N.B.—Contract has been awarded by the city council for repairs to trestle on West Side, to E. A. Farren. Contract price, $1,898. Rejected tenders from R. R. Lee, $2,385; J. A. Adams, $2,667; S. H. Mayes, $2,700; H. O. Clarke, $2,800; Ring and Irons, $3,100; Engineers and Contractors, $3,160; W. R. Monroe, $3,257. G. N. Hatfield, city engineer.

Toronto, Ont.—The officials of the Metropolitan church have commenced tearing up the old concrete pavement on the church grounds and will erect 32 standards for lighting purposes.

Toronto, Ont.—Contract has been awarded by the board of control to James Morrison Brass Mfg. Co., Toronto, for supply and delivery of 2,400 stop cocks. Contract price, $1.80 each.

Toronto, Ont.—Contract has been awarded by the board of education for installation of a 3.0 system oil-burning equipment for Glenholme school, to Sheppard and Abbott, $2,556, and for the John Ross Robertson school to Fess Oil Burners, Ltd., $3,547.

Toronto, Ont.—Contract has been awarded by board of control for supply of piping as follows: 24 and 20 ins. diam., cast iron, to National Iron Corporation, Toronto, $108.85 and $91 per length; 16 ins. lap-welded, to Drummond, McCall and Co., $6,286. Supply of valves as follows: 24 ins. diam., Bawden Machine Co., $3,240; 20 ins. diam., Drummond, McCall and Co., $330. Supply of kerosene engine for asphalt plant, to International Harvester Co., $525.

Vancouver, B.C.—City council decided to purchase 10 dump cars to haul gravel from Coquitlam, B.C.

Vancouver, B.C.—Tenders will be received until 12 o'clock noon, October 15th, by city council, for supply of 4,000 lin. ft. of 2.5 ins. rubber-lined cotton hose for the fire department. J. Stuart, purchasing agent.

Vancouver, B.C.—Coughlan and Sons, shipbuilders of Vancouver, will construct a great graving dock on property recently acquired on Burrard Inlet. It is understood that the company plans to continue production of large-capacity steel ships for private use.

An Important New Edition—Just Issued

PRINCIPLES OF REINFORCED CONCRETE CONSTRUCTION *Third Edition. Revised and Enlarged.*

By F. E. TURNEAURE, Dean of the College of Engineering, University of Wisconsin, and E. R. MAURER, Professor of Mechanics, University of Wisconsin.

Covers in a systematic manner those principles of mechanics underlying the design of reinforced concrete, and presents the results of all available tests that may aid in establishing coefficients and working stresses. In its new, rearranged form, this book is strictly up-to-date.

xii+485 pages. 6 by 9. Fully Illustrated. Cloth, $3.75 net.

"JOHNSON'S GREAT BOOK REWRITTEN"

MATERIALS OF CONSTRUCTION

By the late J. B. JOHNSON. Fifth Edition by M. O. WITHEY, Associate Professor of Mechanics in the University of Wisconsin, and JAMES ASTON, Metallurgist with the A. M. Byers Co. of Pittsburg. Edited by F. E. TURNEAURE, Dean of the College of Engineering of the University of Wisconsin.

A standard reference book for the practicing engineer. The subjects of structural clay products, limes and plasters, Portland cement, working and testing of concrete, the methods of manufacture of the metals and alloys, the corrosion and protection of metals, and the decay and preservation of timber are treated in detail and in an up-to-date manner. Adequate illustrations are given, as are also diagrams and charts.

xx+840 pages. 6 by 9. Cloth, $6.00 net.

A CONSTANT ASSISTANT FOR PRACTICING ENGINEERS

THE ENGINEERS' MANUAL

By RALPH G. HUDSON, S.B., assisted by JOSEPH LIPKA, Ph.D., HOWARD B. LUTHER, S.B., Dipl.Ing., and DEAN PEABODY, Jr., S.B., of the Massachusetts Institute of Technology.

Presents engineering formulæ, mathematical operations and tables of constants in a consolidated form. Engineers will appreciate the quick and accurate results this book will enable them to obtain without the necessity of searching through several volumes.

iv+315 pages. 5 by 7½. 227 figures. Flexible binding, $2.00 net.

Vancouver, B.C.—Tenders will soon be called for construction including necessary dredging and filling, of the C.P.R. Co.'s new pier, to be located between piers "A" and "D," on Burrard Inlet and to cost several million dollars. F. W. Peters, general superintendent for C.P.R. in British Columbia.

Walkerville, Ont.—Hiram Walker and Sons, Ltd., are calling tenders until October 6th, for construction and delivery of one 3,500-gals. per min., turbine-driven, centrifugal pumping unit for the pumping station supplying water to the Walkerville Water Co. R. W. Pratt, consulting engineer. C. D. Brown, secretary-treasurer.

Windsor, Ont.—Ratepayers have endorsed by-law providing for purchase of a motor fire engine. Estimated cost, $15,000.

Winnipeg, Man.—Tenders will be received by the public school board until 5 p.m., October 9th, for supplying 1,056 school desks. P. H. Smith, secretary-treasurer.

Winnipeg, Man.—Ratepayers will vote on by-law providing for establishment and operation of a modern milk and milk product distribution plant. Estimated cost, $600,000.

Winnipeg, Man.—Tenders will be received until 3 p.m., October 6th, by the committee on fire, water, light and power, for supply of electric cooking ranges. C. J. Brown, city clerk.

Condensed Advs.

Advertisements under this heading at following rates per insertion, with fifty cents per insertion as minimum rate in any case; "Positions Wanted," one cent per word; all other condensed advertisements, three cents per word. Payable in advance; 50 per cent. extra if charged.

WANTED technically trained man, with view to taking up designing of electrical apparatus, principally A.C. motors. An opportunity for the right party. Box 9, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER.—15 years' experience since graduation—wants connection with Consulting Engineer or Contractor, for full or part time. Good education, wide experience, and creditable record in construction, including design, estimating, reports, and supervision. Box 11, *The Canadian Engineer*, Toronto.

MANUFACTURER in Eastern Townships, having good facilities and considerable experience in the production of a wide variety of machinery lines, desires to undertake the manufacture (for the Canadian or export trade) of American or English machinery. Full particulars gladly upon request. Box 396, *Canadian Engineer*, Toronto.

MECHANICAL DRAUGHTSMEN.—Wanted first-class man, experienced on details of crane and conveying or paper machinery. Technical training preferred, but must be able to produce results and accept responsibility as well as handle detail design. Also required two or three men with knowledge of machine design and ability to produce detail drawing ing with accuracy and despatch. Apply giving experience and salary required in writing to the Mechanical Engineer, Dominion Bridge Company, Limited, Montreal. 358

COMMISSARY work for construction undertakings is my specialty. Before entering this line, I had eight years' experience as an accountant in the Canadian Bank of Commerce in Toronto and other Canadian cities. Am a Canadian, married, good references. During last year of war had entire charge of all feeding and living accommodations, timekeeping, etc., for large shipbuilding corporation in United States. Interview solicited. Address Box 398, *Canadian Engineer*, Toronto.

Tenders Called For

UNITY, SASK.

Sealed Tenders registered and endorsed on the envelope, Tenders for (tender bid on) and addressed to J. M. Jensen, Secretary-Treasurer of the Town of Unity, Sask., will be received up to 6 p.m., October 15th, 1919, for the supply, delivery and erection of the following machinery and materials and for the performance of certain works:—

Tender A. For the supply, delivery and erection of one internal combustion engine.
Tender B. For the supply, delivery and erection of one generator excitor, switch-board, transformers, meters, etc.
Tender C. For the supply and delivery of one oil storage chamber.
Tender D. For the supply and delivery of pole, wire and line material.
Tender E. For the erection of electric pole line.
Tender F. For the erection of Power station and cooling tank.

Marked cheque for five per cent. (5%) of the amount of the bid must accompany each tender.

Complete sets of plans and specifications may be seen at the office of the Consulting Engineers, Saskatoon, at the Secretary-Treasurer's office, Unity, Sask. Specifications on tenders A., B., C. and D. may be seen at the office of *The Canadian Engineer*, Winnipeg and Toronto, and the Contract Record office, Montreal.

J. M. JENSEN, Esq.,
Secretary-Treasurer,
Unity, Sask.
MURPHY & UNDERWOOD,
Consulting Engineers,
Saskatoon, Sask.
352

NOTICE TO CONTRACTORS

Sealed tenders marked "Tender for Concrete Structures" will be received by the undersigned until 12 o'clock noon on Tuesday, October 14th, 1919, for the construction of the concrete structures on the Provincial Highway in the Township of Pittsburgh. Plans, Specifications and Forms of Tender may be seen on and after Monday, October the 6th, at the Office of the Resident Engineer, Gananoque, at the Office of the City Engineer, Kingston, and at the Office of the undersigned. A marked cheque for Five Hundred Dollars payable to the Minister of Public Works and Highways Ontario must accompany each tender.

The lowest or any tender not necessarily accepted.

W. A. McLEAN,
Deputy Minister of Highways.
Department of Public Highways, 359
Toronto, September the 30th, 1919.

Among the newly-incorporated companies which were recently granted charters by the British Columbia government is the Cameron Construction Co., Ltd., which will take over the business formerly carried on at Victoria, B.C., by S. Cameron, contractor and lumber merchant; also the Veterans' Engineering and Contracting Co., Ltd., with authorized capital of $50,000.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Studies in Surface Area Proportioning Method

Discussion of R. B. Young's Paper Published Under Above Title in the June 26th, 1919, Issue of The Canadian Engineer—Surface Area vs. Fineness Modulus—Results of Tests on Bulking Effect of Moisture in Sands

By LLEWELLYN N. EDWARDS
Senior Highway Bridge Engineer, U.S. Bureau of Public Roads

IN a theoretical study, having for its object the development of a well balanced, practical method for designing concretes, we are inevitably bound to recognize two natural divisions of the subject.

These divisions are, however, very closely interrelated and cannot be considered altogether independently. One of these involves a consideration of the physical and chemical properties of the constituent materials; the other a consideration of the methods and operations which enter into the "transition" or "making" stage.

Experience has amply proven that the latter may operate to vitalize and to develop in the finished product all the latent

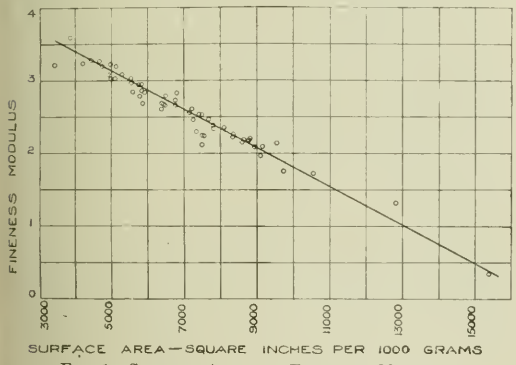

FIG. 1—SURFACE AREA VS. FINENESS MODULUS

functions possessed by the materials or, on the contrary, they may serve to render these functions wholly, or in part, impotent. inert and useless.

It is a situation in which we have two groups of forces tending under favorable conditions to co-ordinate and under unfavorable conditions to disrupt. Naturally enough this dual condition has resulted in a certain amount of confusion in the interpretation of results obtained from experimental tests.

The theoretical studies made by Mr. Young have shown quite conclusively that the grading of the aggregate, or more specifically its surface area, bears a very definite relation to the strengths of mortars and concretes. The relations which he has shown to exist between the surface area, and the cement and the water contents of the mix, are fundamental. Further studies and experimental tests will show a still wider application of this surface area factor than has yet been developed.

When the surface area method of proportioning mortar and concrete mixes was first presented, discussion brought forth the claim that the grading of the aggregate, and consequently its surface area, influenced the strength of a mortar or a concrete only to the extent of fixing the quantity of water necessary to produce a plastic mix. In view of my own investigations and the conclusions drawn from them, I was prepared to accept this notion only with definite limitations, rather than in the "blanket form" in which it was offered.

It is obvious that if we are to establish a uniform method for the testing of the mortar and concrete-making qualities of sand and stone aggregates, we must aim to eliminate factors depending upon the judgment and personal equation of laboratory operators.

The visual or "guess by eye" determination of a "plastic mix" is too indefinite for adoption as part and parcel of such a method.

The writer recognizes fully the importance of the water content of mortar and concrete mixes, both as regards its proper function and its influence when used in excess of that required for the fulfilment of that function. However, he is not prepared to believe that the interpretation of its full effect is based upon the relation of the water to the cement contained in the mix, that is, upon the water-cement ratio.

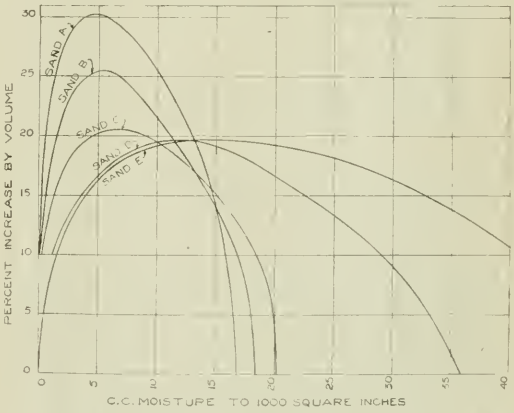

FIG. 2—BULKING EFFECT OF MOISTURE IN SANDS—VOLUME INCREASE IN RELATION TO AREA-WATER CONTENT

The fundamental principles of the surface area method of proportioning preclude the unqualified acceptance of this ratio. In so far as the surface area method is concerned, it is an indirect function rather than a primary one. It varies rather indirectly with the richness of the mortar or the concrete mix.

It is of interest to note that in Table No. II.,* Mr. Young has brought out very clearly the effect of the cement content as tending to vary the water-cement ratio, and has shown that for uniformly moist mixes this ratio is variable. His conclusions are in full accord with the consistency theory of the surface-area method.

The theoretical studies described by Mr. Young do not touch upon the effect of sandy dust (material passing a No. 100 sieve) in its relation to the water content of mortar and concrete mixtures. In the very limited concrete tests described in the writer's paper published in *The Canadian Engineer* in July, 1918, the dust content of the sand aggregate was treated as having the same surface area as an equal portion of material passing a No. 80 and retained upon a No. 100 sieve, and the cement content was proportioned accordingly. As regards the water content of the three concrete mixes described, the paper referred to states that the water content of the mix was sufficient to produce a saturated, sticky, semi-plastic mortar showing no free water. In other words, the water content was determined by visual examination rather than by a specific rule. The speaker's investigations of the surface area method had not then extended to the development of a rule or formula for the determination of the water content of a uniformly moist concrete mix. However, the results of the tests appeared to be amply consistent to indicate the adaptability of the surface area method to concrete mixes, and for this reason alone they were included.

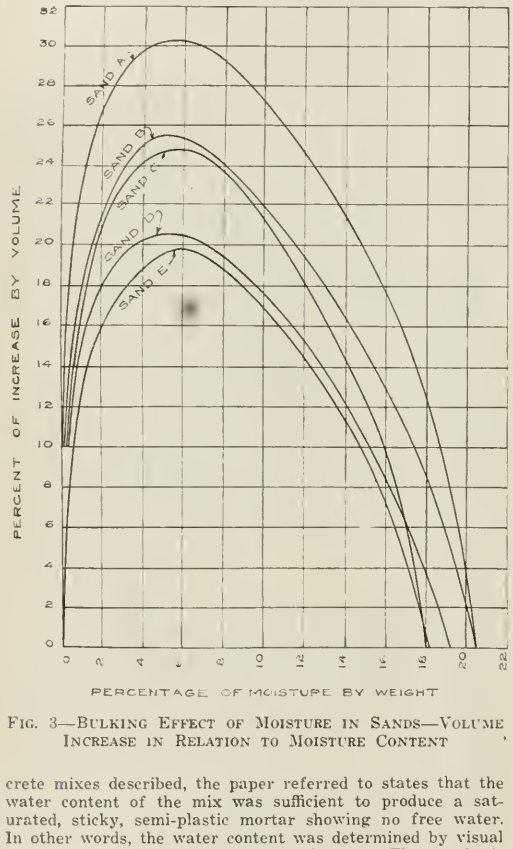

FIG. 3—BULKING EFFECT OF MOISTURE IN SANDS—VOLUME INCREASE IN RELATION TO MOISTURE CONTENT

Tests made within the past six months with the object of obtaining information relating to the effect of sandy dust, have shown quite conclusively that the assumptions just referred to were entirely wrong in principle. Speaking briefly, these tests show that in proportioning the cement content, no allowance should be made for the surface area of dust material and that the water allowance for moistening the dust is nearly equal per unit of weight to that required per unit weight of cement. In other words, we must treat the dust as a "dilutant" or "extender" of the cement, rather than as a component part of the sand aggregate. Incidentally, it may be said that these tests have shown ample evidence of both the reliability and the advisability of the common practice of limiting the dust content, by weight, to approximately 5% of the sand aggregate.

*See *The Canadian Engineer*, issue of June 26th, 1919, p. 565.

Investigation of Various Aggregates

For a proposed concrete structure, the consideration of possible sources of supply of aggregates frequently involves the laboratory examination of the concrete-making qualities of two or more different aggregates varying in their granulometric composition and other physical properties. The field conditions attending the mixing, handling, placing and finishing of the concrete, as well as the ultimate strength, durability, etc., of the concrete producible from them, require that the relative merits of these aggregates be determined under conditions eliminating variations in the relative plasticity and the final strength of the cement matrix which performs the function of holding together the particles of the sand and stone aggregates. When the aggregate contains sandy dust it is important that allowance be made for the quantity of water required to moisten it.

Having determined under uniform conditions the relative concrete-making values of the materials, the question of their adaptability to the production of workable, plastic concrete mixes capable, in the "transitory" stage, of being formed with a reasonable amount of work into the various shapes required in its adaptation to the construction of bridges, buildings, roadways, etc., can be fully and systematically considered. The quantity of water required for absorption by the aggregate and for moistening its surfaces remaining constant, an increase in the water content over that used in the tests, produces a dilution of the cement paste which ultimately results in a weakening of the cement matrix. Unfortunately, many investigations have overlooked the basic importance of the cement matrix, and have evolved their investigations upon the assumption that the mobility of the mix is a primary rather than a secondary factor. The very nature of the component materials and the varied proportions in which they are used, render such an assumption untenable.

The determination of the effect upon the strength of mortars and concretes resulting from an increase in the water content has been the object of studies and tests made by several investigations, so that a considerable volume of information is now available. Doubtless the tests, formulas, etc., reported by Prof. Duff A. Abrams, Lewis Institute, Chicago, Ill., are the most complete, exhaustive and reliable.

Laboratory Testing of Concretes

Having discussed, at least to a limited degree, the fundamental requirements for the investigation of aggregates, it will not be amiss to indulge in a brief consideration of the conditions which are of vital importance to the laboratory testing of concretes and to the establishment of standard methods and practices. While several conditions of lesser importance might be enumerated, the three most important basic conditions entering into comparative tests are the following:—

1.—The water content of the mixes must be sufficient to permit the production, without loss of water, of uniformly sound, well-moulded specimens.

2.—The water content of each mix must be so proportioned as to produce for a given cement a uniformly strong cement matrix.

3.—The cement content of each mix must be so proportioned as to provide a uniform and equal quantity of matrix in relation to the surface area of the aggregates.

In a series of tests adapting the principles just mentioned to laboratory conditions, it has been found that concrete mixes containing a uniform broken stone aggregate,

sand aggregates differing in their granulometric analyses (their surface areas varying from 1,830 to 2,490 sq. ft. per 100 lbs.), and with cement contents varying (by ½ lb.) from 1 lb. to 4 lbs. per 100 sq. ft. of surface area of total aggregates, produced generally excellent working conditions when the water content of the mixes was proportioned as follows:—

Water to moisten cement equals weight of cement multiplied by the percentage of water required to produce normal consistency paste.

Water to moisten surface area of aggregates equals 12 cc. per 1,000 sq. ins., equals 0.381 lb. per 100 sq. ft.

Water to moisten dust, if any, equals 0.381 lb. per 100 sq. ft. of surface area, its surface being assumed to be equal to that of sandy material passing a No. 100 sieve and retained upon a No. 200 sieve.

In these tests the concretes produced from lean mixes containing 1 lb. and 1½ lbs. of cement per 100 sq. ft. were harsh, and required an extra amount of labor to effect the placing in the moulds. All other mixes were plastic, the cement paste which they contained being sufficient to lubricate the surfaces of the aggregates. The fat mixes, containing over 3 lbs. of cement per 100 sq. ft., could have been easily placed in the moulds had they contained a slightly less quantity of water. Economy of construction requires that the increased strength thus attainable be taken account of in actual field construction operations.

The origin and development of the water factor for moistening the surfaces of the aggregates and dust will be described by the aid of diagrams.

Surface Area vs. Fineness Modulus

At practically the same time as Mr. Young was seeking to establish a mathematical relation between surface area and fineness modulus, I was engaged in a somewhat similar effort, not with the object of corelating these methods, but, instead, of finding out just how fineness modulus short-circuited the surface area, as had been claimed.

Just how much efficiency is lost by the short circuit is not clear. Fig. 1 shows the results of studies made with over fifty natural sands. It gives the impression that possibly the fineness modulus is intermittently or otherwise "grounded" on surface area. However, like Mr. Young, the writer was unable to establish a definite mathematical relation.

Reverting now to the consideration of the water content of the concrete test mix in its relation to the surface area of the aggregates, it is a well-known fact that while the weights of sands vary with the character of the rock materials from which they take their origin, and also with their granulometric composition, yet, for any given sand, its weight per cubic foot when dry is greater than its weight when wet, provided, of course, that in each case the sand is shoveled into the measuring receptacle. This condition holds true even when the wet sand is subjected to a moderate amount of compacting.

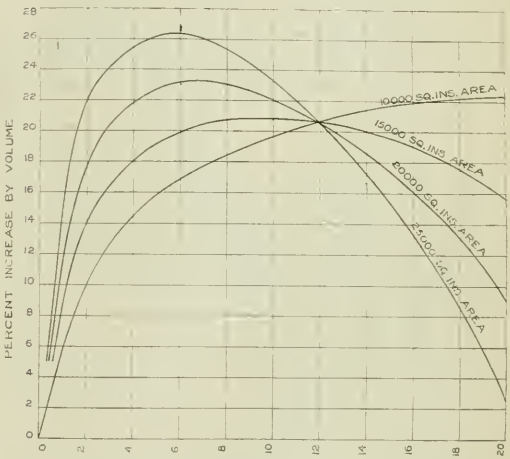
Approved practice in mortar and concrete testing is based upon the use of weighed quantities of dry aggregate, and only upon this basis can the test results be properly interpreted. It is axiomatic that if results consistent with those secured in the laboratory are to be obtained upon field construction work the conditions under which the aggregates are measured, more especially the sand aggregate, must be such as to assure reasonable uniformity in the net volume.

Bulking Effect of Moisture

Notwithstanding the above conditions, there is a marked paucity of published data relating to the effect of varying quantities of water contained in sand aggregate used in mortars and concretes. Its absence is evidence that this factor has not been given sufficient attention by engineers, architects and construction men.

With the primary object of securing information relative to the "bulking" effect of moisture in sands differing in their granulometric analyses, tests were made by the Department of Works, Toronto, under the direct supervision of the writer. Paradoxical as it may seem, these tests have shown that the surface area of the sand particles is a direct function of the volume increases produced by varying the quantity of water.

In describing the tests very briefly, it may be said that the volume-weight method was used for determining the quantity of each sand to be used in the tests; the weight being determined in each case from an average of four tests. Natural sands were used. Two series of tests were made upon each sand, the water content being varied in the first in relation to the weight of the sand and in the second in relation to its surface area. A uniform distribution of the water was secured by working the sand with a trowel or other tool. To secure the desired degree of accuracy, each intermediate test was repeated four times. From these tests, involving eleven different sands, average volume-increase curves were determined. Fig. 3 shows, for five of these sands, the relation of volume-increase to percentage of water content. One per cent. of water was amply sufficient to coat thoroughly the surface of the sand particles. The "bulking" effect resulting mainly from the cohesive action of this small quantity of water, ranged in the tests from 11% to 23%. Two other interesting features of this diagram are the "saturation" stage producing maximum volume, when the water content approximates 5% to 7%, and the "flooding" stage, at which the volume of the sand is the same as that originally



PERCENT INCREASE BY VOLUME

25000 SQ. INS. AREA

Fig. 4—Bulking Effect of Moisture in Sands—Experimentally Determined Relation of Volume Increase to Area-Water Content

occupied by it when thoroughly surface dried. The water content for the latter varied from 18% to 28%. Careful observation at this stage failed to discover a tendency of the sand to fall below its original dry volume.

The area-water series of tests led to a rather interesting and entirely unlooked for discovery. Fig. 2 shows, for the five sands shown in the diagram "Fig. 3," the relation of volume increases to the area-water content Special attention is called to the indications of the existence of a "nucleus" common to all the curves. Although the writer had confidently expected that this series of tests would show the existence of a relation of "bulking" effect to the area-water content, yet this indication of a condition common to all sands tested was quite unforseen.

From a systematic study of the experimentally determined curves, we have deduced those shown upon Fig. 4. Each curve in Fig. 4 was derived mathematically from a consideration of all those determined experimentally. Attention is called to the actual existence of the "nucleus" indicated upon the previous diagram. The water-area ratio of this rather mysterious point is 12 cc. per 1,000 sq. ins., which corresponds to the water factor (0.381 lbs. per 100 sq. ft.) used for moistening the surface of aggregates and dust in concrete test mixes.

The claim is not made that the volume-moisture condition just described bears a direct relation to the many factors involved in concrete making. However, its actual use in this connection has indicated its efficiency as a working tool. We can, I believe, ill afford to cast it aside without a full and careful trial to prove or disprove its value. It is entirely possible that physical factors other than cohesion and adhesion enter into this peculiar volume-moisture condition. In so far as the speaker has a knowledge, its existence has not been previously discovered. However, independent and more recent investigations made by Mr. Young have shown corroborative and unquestionable evidence of its existence.

Since the moisture content in a sand has the rather remarkable effect of increasing its volume by holding the sand particles somewhat rigidly in positions different from those they would readily assume when dry, it seems reasonable to aim to control this "bulking" effect, so far as is possible, in test mixes for concrete.

There is no evidence that the "bulking" effect of the moisture in sands has been given consideration either in written specifications or in field operations incident to mortar and concrete-making. Its consideration will show the fallacy of the commonly used volumetric method in so far as resulting strengths are affected by the moisture contained in the sand aggregate, and will inevitably lead to the opinion that the adoption of methods and appliances whereby the aggregates will be measured by weight rather than by loose volume, will result in a greater uniformity and reliability of the mortars and concretes produced. Important practical considerations render it advisable to continue the present practice of using in concrete mixes a volume of mortar equal to approximately one-half of the gross volume of the stone aggregate.

Proposed Tidal Power Development at Hopewell

Dams and Power-House at Confluence of Petitcodiac and Memramcook Rivers—Initial Installation of 90,000 H.P. Would Cost Approximately $122 per H.P.—Paper Read at Engineering Institute's Fifth Professional Meeting, September 11th, at St. John, N.B.

By W. RUPERT TURNBULL
Consulting Engineer, Rothesay, N.B.

FIRST, and in a brief manner, we should review the tidal developments and proposals of the past, so that you will be led, as I have been, to think that the first large tidal development in the world will probably be carried out at Hopewell, N.B., the little village that lies closest to the tidal estuaries, the Petitcodiac and Memramcook, where nature has founded two great natural reservoirs with the exception of the dams that must be built to complete them.

Old charters show that tidal power was used in England, for grinding corn, as early as the 11th century, and tidal mills have been in operation for the same purpose, from that time to the present day. The following extracts are taken from an excellent article by W. C. Horsnaill, that appeared in "The Engineer," London, Eng.:—

"No records exist showing how the earliest tide wheels were arranged, but particulars are available of several mills which were erected in the eighteenth and nineteenth centuries. In the earlier historic mills no attempts were made to produce a fall, the power being obtained from the flow of the water into and out of the pound. To develop power in this way, a wheel similar to the paddlewheels of steamships was used, but with a reversed action; that is to say, the flow of water drove the wheel. This arrangement entailed the raising and lowering of the wheel to suit the rise and fall of the tide, as only the bottom floats could be immersed if the best results were to be obtained.

Layout of Old Mills

"A corn mill at one time existed at East Greenwich which was driven by tidal power in the way we have described. The pound has an area of about 4 acres and the wheel measured 11 ft. in diameter by 26 ft. long. The power was transmitted by a bevel gear at either end of the water-wheel shaft, the pinions being free to slide up and down two square vertical spindles. The water-wheel and bevel gears were mounted upon a frame which was caused to rise and fall to suit the tides, and the power was transmitted by either bevel wheel according to which way the water-wheel was running, the other bevel pinion being thrown out of gear. By these means the machinery in the mill was always driven in one direction, in spite of the reversal of the water-wheel at each turn of the tide.

"The movable frame, with the water-wheel and gear, weighed some 20 tons and the bottom of it was extended to form a kind of shutter, which filled up the opening underneath the wheel race, all the water flowing into or out of the pound being thus compelled to pass through the wheel.

"Another type of wheel was devised to overcome the drawback of having to move up and down with the tide. This wheel was fitted with hinged floats, which arranged themselves across the stream at the bottom of the periphery, while they travelled through the water edgeways during the remainder of each revolution. With floats of this type the wheel was fixed, and the tide gradually rose over it until in some cases complete immersion took place.

This Design Soon Discarded

"An arrangement of the sluices was also adopted to compel the water to pass through the wheel in the same direction, whether flowing in or out of the pound, thus doing away with the need for reversing gear between the water-wheel and the machinery to be driven.

"These wheels must have been very inefficient, as the loss of power caused by the drag of the upper portion when covered was serious, and the design was soon discarded.

"Following these earlier mills came the more recent examples, many of which are still in existence, while a few of them may be seen in operation. The older mills aimed at using the current of water caused by tidal action, and advantage was taken of the flow in either direction. The more modern tide wheel is arranged to operate with a considerable fall, and only develops power when the water is flowing out of the pound.

"The undershot wheel with straight radial floats is usually adopted, and the mill is started at half ebb or a little later, work being continued for about five hours, or until the water rises under the wheel and chokes the tail race. These arrangements give only five hours of working during each tide."

Listing the tidal mills that actually exist: There is a mill at Woodbridge of 10 to 12 h.p. and one at Walton-on-the-Naze of 85 h.p. These are both small powers, working on a low range of tide, and with only a single, small, natural reservoir that allows of only a partial use of the tidal power for a comparatively short period of time, but Mr. Horsnaill shows that if modern turbines were installed at the plant at Walton-on-the-Naze, and the power used to develop electricity instead of grinding corn, it would show up as a commercial development somewhat better than gas power in spite of a heavy outlay for storage batteries, which would be necessary at a plant situated as is Walton.

The number of proposals for tidal plants is very considerable, and while I think I should not take up your time by discussing all of them, it is worth while to examine a few of the more serious ones.

James Saunders discussed, in the "Engineering Review" of London, Eng., three great plants for developments in England; namely, at Chichester Harbor, at the Menai Straits, and in the Bristol Channel. But in each case either the head of the water was too low, or the cost of forming the artificial reservoirs was too great, to make the proposals commercial at present. His most promising scheme is that for the Bristol Channel, where the tidal head is quite sufficient for successful operation but where the cost of forming the great artificial reservoirs that would be required is prohibitive in relation to the power obtained. The total cost of the plant figured out at $47,000,000 and the horse-power at 240,000 so the cost per h.p. would be $196.

Cost Excessive in England

C. A. Battiscombe, before the London Society of Engineers, also made a tidal proposal for the Bristol Channel, but his cost works out at $237 per h.p., and while neither of these figures would be too high for commercial developments *in some localities*, they are too high to interest English capital, for England is still a country of cheap coal, and in examining *any* hydro-electric development we must constantly keep in mind the cost of power from other sources.

Mr. Boving has proposed a tidal plant for the River Dee, but no estimates of costs are given; and coming nearer home, there have been numerous proposals for obtaining power from the tides at Sackville, at Cape Split, and at the Reversible Falls of St. John. To get *continuous* power at any of these sites, it would be necessary to form large artificial reservoirs, and the formation of such reservoirs is so costly that these proposals are not, at present, commercially feasible.

The Three Main Requirements

The three great desiderata for a tidal plant are:—

1.—That there should be sufficient height of tide to obtain a good head.

2.—That there should be two natural reservoirs of large size so that continuous power can be obtained.

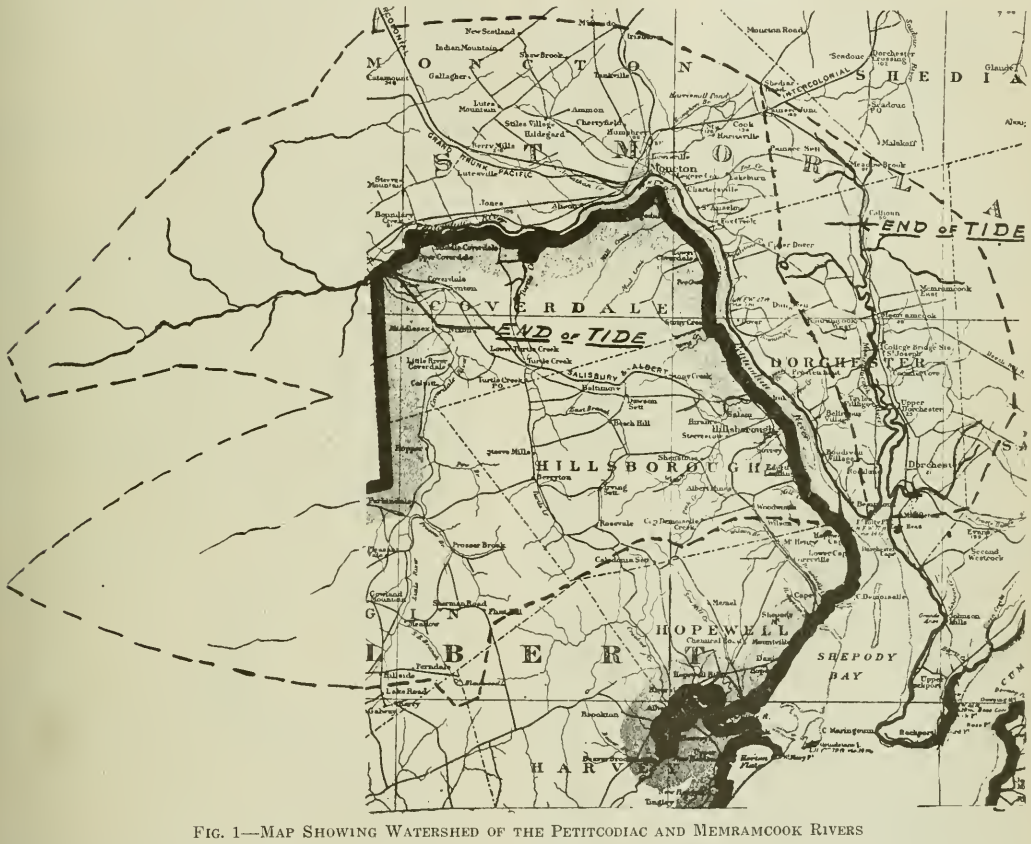

FIG. 1—MAP SHOWING WATERSHED OF THE PETITCODIAC AND MEMRAMCOOK RIVERS

3.—That the power plant should be central to the population that would be served.

And it is these three desiderata that lead us to suppose that the *first* great tidal development in the world will take place at Hopewell. Here we have two large reservoirs almost completely formed by nature, we have a tide which is exceedingly regular and that ranks among the highest tides in the world, with a spring rise of 45 ft., a neap rise of 38 ft., and a normal neap range of 32 ft., and we have this power centrally located to a present population of 250,000 who are *literally starving* for cheap electric power, with no other hydro-electric development in sight, except small ones and those that are too distant from the centres of population to make their development commercial at the present time.

I have examined many other sites for tidal power in those parts of the world where the tides are sufficiently high

to make tidal power at all possible, and I am firmly convinced that we have at Hopewell the site that is most promising at the present time, from a commercial standpoint.

I will now discuss the principle which I have proposed for obtaining continuous power from these great tides. Fig. 1 is a map of the two tidal estuaries, the Petitcodiac and the Memramcook rivers. This map shows the general trend of these rivers, and their confluence at Hopewell, and it also shows the fresh-water drainage areas of the two rivers, which, although a minor item as compared to the great volume of salt water that flows up and down these rivers, should still be borne in mind in reviewing this proposal.

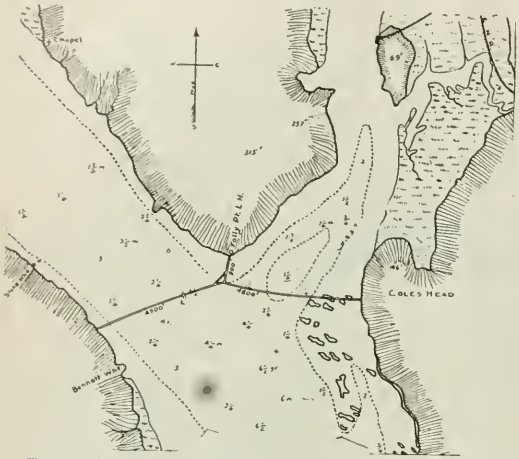

FIG. 2—CONFLUENCE OF PETITCODIAC AND MEMRAMCOOK RIVERS

The dotted lines show the respective drainage areas approximately, and these have been calculated to show a drainage basin for the Petitcodiac of 784 sq. miles, and for the Memramcook of 134 sq. miles, or in the ratio of nearly 6 to 1.

At present the flood tide makes up these rivers for approximately six hours and then turns and flows back into the bay for 6½ hours, and this map also shows the approximate limits of this flow, above which points the streams are fresh water.

Fig. 2 is a scale chart of the confluence at Hopewell of these two rivers, the proposed location of the dams that will be necessary to control the waters, the depths of water at low tide, etc.

Dams Two Miles Long

The western dam would be 4,900 ft. long, the eastern dam 4,800 ft. long, and a wing dam of 900 ft. would connect the two, and it would, of course, be part of the plan to have a highway and trolley line (operated by the plant) over the tops of these dams, connecting up the two main shores and the long peninsula between the two rivers. This highway would only be a matter of local benefit, but it would be of immense benefit to the building up of this locality. At present Hopewell can only be reached from Cole's Head by a little ferry that can only operate for a few hours near high tide. The Petitcodiac is only bridged at Moncton, 19 miles above Hopewell. The Memramcook was bridged at Upper Dorchester, 5 miles above Hopewell, but this bridge is now gone, and the government is at present making borings for a new bridge that will cost about $1,000,000.

At present Hopewell, Hillsborough and the bog peninsula are hard places to get into, and still harder places to get out of, and yet they are regions of great mineral resources that only require, but still await, development. In Fig. 2 is indicated a lock in the western dam, through which vessels could be passed at any suitable time of the tide on their way up and down the Petitcodiac. Hillsborough and Moncton would be provided with deep water harbors instead of the mud flats which they at present enjoy at every low tide. The gates of the locks would naturally be swung by electric power furnished by the nearby power house.

The proposal provides for making the Petitcodiac a high level basin in which the water would always be high, and be replenished at every high tide, while the Memramcook river would be a low level basin to be partially filled from the high level basin and to be always emptied during the latter part of the ebb tide. This arrangement would also suit local conditions admirably, for the Memramcook is exclusively a farming district in which much time and money is at present expended in excluding the tides by means of dykes, and I have been informed by farmers of this valley that they would only wish to have the salt water flood their lands about once in ten years for the purpose of fertilizing them. The navigation of this river is practically nil, so it would hardly be necessary to provide any lock in the eastern dam. Two or three times during a summer a small vessel will lie at the Dorchester Island wharf for the purpose of discharging goods, but these could be as well discharged below the dam and the power company could well afford to pay for the short extra haulage.

Continuous Operation, Varying Head

Fig. 3 illustrates—in scheme but not to scale—the principle that I propose to employ to get continuous power from the tides, with a varying head to be sure, but with the water always passing through the turbines in the same direction, and always with a head sufficient to make turbine operation successful. The diagram shows the confluence of the two rivers, with the necessary dams and gates to control the flow. The gates (J) in the western dam would be automatic flap-gates, opening up-stream, allowing the high level basin (the Petitcodiac) to fill at every high tide. The gates (H) of the eastern dam would be automatic flap-gates, opening down stream, allowing the low level basin (the Memramcook) to empty on every ebb tide. The gates (G and G_1) would be in the nature of lock-gates. They would be operated by electric motors driven by the power-

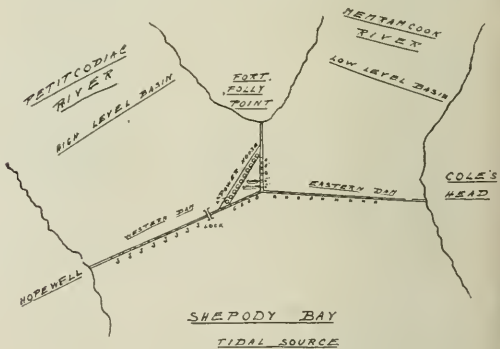

FIG. 3—LAYOUT FOR OBTAINING CONTINUOUS POWER FROM THE TIDES

plant itself, and under the control of the attendants, who would open them and close them, in accordance with the height of the external tide, at stated times that can be fixed for months in advance directly from the tide tables.

The power house is represented as a long building, with turbines (T) extending diagonally from the wing dam to the western dam, these turbines discharging continuously from the high level basin into the common, triangular, spillway.

Let us now follow through a cycle of operations from low tide to the following low tide, remembering that the high level basin was filled automatically at the last high

tide, and that the low level basin has just been emptied during the ebb tide, through the gates in the eastern dam.

Beginning with low tide we may at first leave gates (G) open and allow the water from the spillway to discharge directly into the tidal supply (Shepody Bay), but the head will gradually decrease as the tide rises, and at about 2½ hours rise the attendants close gates (G) and open gates (G¹), allowing the discharge from the spillway to enter the low level basin. Into this low level basin, the spillway will continue to discharge for about 6½ hours, or through the last 3½ hours of flood tide and through the first 3 hours of ebb tide, after which time the water in the low level basin will have so risen, and the water of the tidal supply will have so dropped, that it will now be profitable to close gates (G¹), and open gates (G), and once more allow the discharge to occur directly into the source of tidal supply and give the low level basin time to drain out again on the ebbing tide.

Tide is Very Regular

I think that from this the simplicity of the system itself is evident, but in order to study more fully one of the engineering problems involved, Fig. 4 shows the typical tidal cycle at Hopewell. This curve shows a copy, in per cent. of range plotted against time, of an actual tidal record obtained at the ordinary neap tides by the tide gauge established this summer at Hopewell by the Canadian Tidal Survey, and furnished to me by the courtesy of H. W. Jones of that department. You will note how exceedingly regular the tide is, and how little affected by estuary flow, and this is one of the great advantages of Bay of Fundy

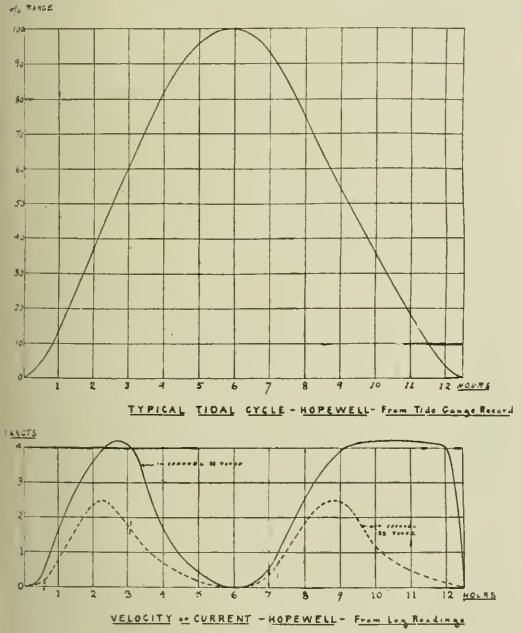

Fig. 4—Typical Tidal Cycle at Hopewell

tides, in general. At certain places in the world the diurnal inequality becomes so great that, for several days there is only one tide in 24 hours, and at Southampton there is a second high water occurring about two hours after the first.

In dealing with the question of tidal power at Hopewell, it must be remembered that although the tide is regular in type, nevertheless the *range* of the tide, and not the *rise* is the limiting factor of our power calculations, and it becomes necessary to establish and work on what might be called a "standard range." For this purpose I have analyzed approximately the ranges that will occur in the course of a year. I call spring tides those whose range exceeds 42 ft. They occur about 15% of the time, and I think no attempt should be made to utilize them especially. I call subnormal neap tides those whose range is less than 32 ft. They also occur about 15% of the time, and some means, which are discussed later, would need to be employed to avoid the impairment of our "standard" amount of power.

All other tides I call ordinary neap tides, with a range, at Hopewell of 32 ft. to 42 ft. They occur about 70% of the time, and its is the lower range of 32 ft. that I think

we should adopt as our "standard range," and the curves and estimates that follow are based on this range of 32 ft.

Fig. 5 shows a tidal cycle at a "standard range" of 32 ft., with an assumed drop in the high level basin of 6 ins. per hr., the level change that will occur in the two basins with the operation of the plant as before described. If the conditions at Hopewell were absolutely ideal, the ratio of effective areas would be as 2 to 1 for the high and low level reservoirs, but unfortunately this is not the case, for the Petitcodiac contains an effective area of about 330,000,000 sq. ft. while the Memramcook has only about 60,000,000 sq. ft., so that the ratio is about 5½ to 1. While the water in the Petitcodiac is dropping 6 ins. per hr., the water in the Memramcook is rising 5½ times this, or 33 ins. per hr., and these level changes are illustrated in Fig. 5, while the changes in effective head on the turbines are plotted in the lower portion of the same figure.

Operation at "Standard Range"

Full lines show the level changes of the high level basin; dotted lines, those of the low level basin. Starting at low water, for 2.35 hours the level of water in the low level basin is unchanged, for the water from the spillway is discharging into the tidal supply direct, but during this time the head is decreasing from 28½ ft. to 13½ft., when it becomes expedient to discharge into the low level basin, when the head will at once rise to 27½ ft.

After this, for 6½ hours the low level basin will rise, but the high level basin will also rise after 4.1 hours (as the

flood tide will then be filling in for 1.9 hours) and we have the head decreasing from 27½ ft. to 22 ft., but afterwards increasing to 23½ft. at 5.2 hours.

After this the head will gradually decrease to 13½ ft. at 9 hours, when the tide in the external bay having sufficiently ebbed, the water from the spillway will be again discharged into it and the head will steadily rise to its previous maximum of 28½ ft. at low tide, as shown by the curve of heads.

The average head, in this case, from low tide to low tide works out at 22¼ ft.

It will perhaps be wondered why I select a drop of 6 ins. per hr. for the high level basin, and what the difference would be if we selected a greater or lesser drop. Up to a certain maximum, which would occur at about 250,000 h.p. and at a 26 in. per hr. drop, the available horsepower increases with an increase in the hourly drop allowed. However, it must be borne in mind that as the hourly drop increases, the maximum head decreases, and the minimum head decreases more rapidly still, and we soon reach a case that cannot well be met by any ordinary turbines.

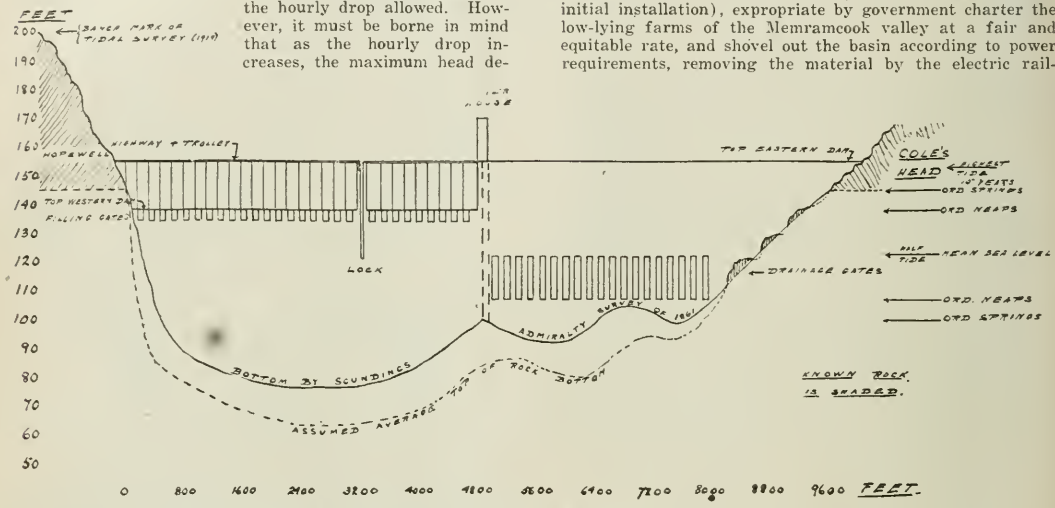

FIG. 6—APPROXIMATE PROFILE OF PROPOSED DAMS, HOPEWELL HYDRO-ELECTRIC PLANT

To illustrate this, a 4-in. drop in the high level basin gives maximum head of 30¼ ft., minimum of 20 ft., and average of 26½ ft., but 6 in. drop gives 28½ ft. maximum, 13½ ft. minimum and average of 22¼ ft., and this seems to be about the maximum relative range over which we can expect a single turbine to act; we could employ duplex turbines, mounted vertically on the same shaft to the same generator, but with separate draft tubes (as suggested by James Saunders), but this means considerable added cost and is to be avoided if possible.

We are thus forced to adopt one of those compromises that are often met with in engineering design, and must adopt a drop in our high level basin that will entail such a range of head that can be successfully met by the turbine designer. I am at present in correspondence with many of the leading turbine manufacturers and have no doubt they can largely overcome this difficulty of this variable head, in a moderate priced turbine, but the whole question of this variable head problem is so novel to them that the correspondence is necessarily lengthy to get them to understand the conditions involved in a tidal plant. However, one maker shows a turbine that gives 5,000 h.p. at 120 ft. head and efficiency of 86%, and also the same horsepower at 220 ft. head and 80% efficiency, all at a constant speed of 300 r.p.m., so I think we can have no doubt that once the conditions involved at Hopewell are understood by the manufacturer and designer, we can obtain turbines that will meet the assumed condition of a 6 in. hourly drop in our high level basin and with a probable average turbine efficiency of about 83%.

As a matter of fact the initial installation called for at the present time by the existing population, would be about 90,000 gross horsepower, and we can readily calculate that this corresponds to an hourly drop of 4 ins. in the high level basin. Now, as the population grows, and the demand for electricity increases from 90,000 to 120,000 h.p., we can steadily improve the ratio of the two basins and thus greatly improve our power output (up to say 200,000 h.p.) and yet never exceed the limit of 6 in. hourly drop which I have assumed as the present practical limit of single-turbine operation.

To improve this basin-ratio to the ideal condition in which the Memramcook would have half the effective area of the Petitcodiac, I propose to use electric shovels and an electric tramway (both operated by surplus power from the initial installation), expropriate by government charter the low-lying farms of the Memramcook valley at a fair and equitable rate, and shovel out the basin according to power requirements, removing the material by the electric railway and dumping it below the eastern dam where it would be largely carried away by the tide or could be formed into a useful embankment—wharf, railway terminal, or the like.

Fig. 6 shows the approximate profile of the western and eastern dams. Since it would not be policy to attempt to get the extra power that spring tides would give, the western dam need only have the height of high water, ordinary neap tides, but the height of the eastern dam would have to be carried up beyond the highest probable spring tides to insure that the low level basin would never be flooded at high tide. Fig. 6 shows this dam carried 3 ft. higher than the highest spring tide that occurred during a period of 15 years. As before mentioned, the tops of the dams could be utilized as highways, and would thus be of invaluable local benefit, and a light steel structure is indicated on the western dam for this purpose. The masonry width called for by the calculations would not be sufficient for a roadway, but a light steel structure could be winged out on top of the dams and made of sufficient width to carry a good roadway, an electric tram and the power transmission lines that would go both west to St. John and east to Halifax.

The flap-gates for filling the high level basin and emptying the low level basin are indicated in the sketch-profile. They should present no engineering difficulties, but they should be designed of sufficient size to pass readily the full volume of water required by the final and maximum development.

We now come to the question of the river bottom and the location of rock for a good dam foundation, and here I must apologize, for I cannot give any exact data. I took

BACKFILLING THE RED RIVER TUNNEL

Concrete Poured Around 60-In. Cast-Iron Pipe in 10x10-Ft. Rock Bore by Dropping it 70 Ft. From Trestle Across River

By J. Armstrong
Division Engineer, Greater Winnipeg Water District, Winnipeg, Man.

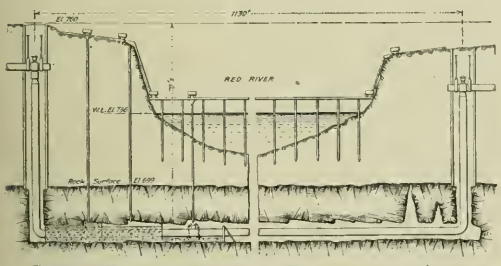
OVER 1,100 ft. of the new Winnipeg aqueduct is in tunnel under the Red river, with the roof of the tunnel about 70 ft. below the high part of the ground and 40 ft. below the river level. The 60-in. cast-iron pipe carrying the water was concreted here into the 10 by 10-ft. tunnel by concrete dropped through holes bored at intervals from the surface.

The tunnel bore is through the solid limestone rock, the rock roof being some 17 ft. in thickness, with overlying soils of various clays, silts, and other river deposits. The rock was found to be fairly hard but badly seamed both horizontally and vertically and containing many pockets of varying size up to two or three cubic yards, evidently the result of water action at some remote period, but now filled with a white, chalky clay. The first 400 ft. of the tunnel from the eastern end discharged considerable water into the boring from these seams, although not in sufficient quantity to require the aid of compressed air, a 4-in. submerged centrifugal pump handling the water at all times with ease. The remaining 600 ft., although seamed and checked, seemed tighter, and comparatively little water was added from this portion.

Practically Perfect Hydrostatic Action

The original tunnel section was designed with a circular roof, but owing to the seamy condition discovered the section was changed to a 10 by 10-ft. square. The eastern shaft is some 2 ft. lower than the western shaft, to facilitate drainage during construction.

The water is conveyed through this tunnel in a 60-in. cast-iron lining. The contract required that after this lining was in place the remaining space in the tunnel bore be backfilled with concrete in such a manner as to guarantee an



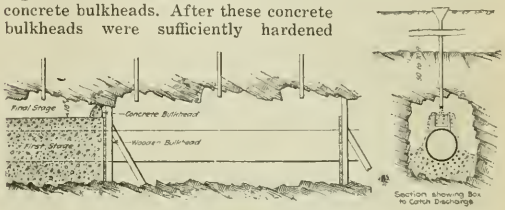
Section Through Red River Tunnel of Winnipeg Aqueduct, Showing Method of Concreting Pipe

absolute filling of all irregularities and pockets. The specifications specifically prohibited the use of compressed air in placing the concrete. After much study the method adopted was by means of well holes bored from the surface through the roof of the tunnel. These holes were drilled with an ordinary well-drilling machine and lined with a 6-in. well casing from the surface to the rock. The spacing of the holes was somewhat irregular but averaged 40 ft., the holes being bored to this spacing at the nearest high spot in the tunnel roof.

For the river crossing a light trestle was built consisting of two-pile bents spaced 8-ft. centres with four longitudinal 8 by 8-in. stringers to act as bracing and to bear the light industrial track carrying the concrete cars. A mixing plant was provided at each end of the tunnel consisting of a ¾-yd. mixer, industrial tracks and concrete cars of various types.

The first operation consisted in the pouring of a concrete floor in the tunnel carefully graded to facilitate the placing of the 60-in. cast-iron lining. This concrete, some 250 yds., was all poured down one hole at the western end and distributed by cars using the same track previously employed in the tunnel excavation and later used to transport the cast-iron pipe.

When the lining was in place the tunnel was bulkheaded off in sections of various lengths and concrete poured until within 18 ins. or 2 ft. of the roof. This was allowed to set and succeeding sections were poured. During the operation a concrete dam or bulkhead was built back on the set concrete, these dams being about 120 ft. apart, thus leaving three well holes between each two concrete bulkheads. After these concrete bulkheads were sufficiently hardened



Sections Showing Details of Concreting Aqueduct by Dropping Through Pipes

to withstand the pressure the final concrete was poured. The two end holes in each compartment were used to discharge the concrete, leaving the middle hole for observation purposes. In every instance when the end holes were filled the concrete rose in the middle or observation hole to the same level, showing a practically perfect hydrostatic action. As these holes provided a head of from 55 to 70 ft. of fluid concrete there seems no doubt that all cavities and seams adjacent to the tunnel section must be completely filled.

For pouring the floor and the main tunnel concrete a mixture of 1 cement to 4 of aggregate was used, all stones passing a ½-in. ring. The stone was kept small to avoid a possibility of choking the pipes. A fairly wet mix was used although nothing approaching sloppiness was required. Observation indicates that aggregate containing stone as large as 1-in. might be safely used in holes of 5½ or 6-in. diameter. Various devices were used to prevent any tendency to segregate the materials of the concrete, the most successful of which was a wooden box slightly larger than a standard nail keg fixed on top of the cast-iron pipe and directly underneath the pipe. The force of the concrete discharging into this box full of concrete gave the constituents a very thorough remixing. As a further precaution an inspector and two workmen were kept in the section being concreted, and properly distributed the concrete. These men were able to work in the concrete until it was within 3 ft. of the roof and it was at this stage the concrete dam or bulkhead was built on previously set concrete preparatory to the final or grouting operation. These men usually sank half way to the knees in the concrete, which will give some idea of the wetness of the mixture. Spouts with a hopper swiveled under the holes were also used successfully but were awkward to handle and seemed to involve more extreme effort than collecting in the box and then working along by shovel and tramping. The inspector had a field telephone installed in the tunnel giving ready communication with the mixer when instructions were necessary.

Filling Top Three Feet

The final stage was the filling of the space left as just described, the mixture used being 1 of cement to 3 of aggregate, the aggregate being in district parlance "rejected sand"; in other words, the excess finer materials screened from the pit run during the process of assembling the standard aggregate. This material was fairly well graded from a coarse sand to fine sand. As before indicated, this concrete was poured down the two outside holes of a three-hole set. A few batches quickly formed a cushion under the hole thus preventing segregation, as was easily proved by samples taken from the middle or observation hole.

The holes with one exception were bored directly on the centre line. This exception was at the eastern end where the rock was exceptionally seamy, and a couple of bad caves resulted. The second one developed an opening completely through the rock, letting in a considerable flood of water and earth from above; not, however, before the caving was visible on the surface 70 ft. above.

Some hesitation was felt about driving a hole through this shaky roof, and fortunately one of the large water worn cavities before mentioned was found here extending some 4 ft. off line of the tunnel. The pouring hole was accordingly driven here without the loosening of any further rock from the roof. Considerable water was coming through the roof in this section and was collected on a sheet-iron roof and run to wooden troughs along the side and carried beyond the concreting in progress.

For the final stage of pouring at this section, a 2-in. pipe was run through the concrete bulkhead and extended upward to near the upper surface of the rock, some 12 or 14 ft. above the roof line of the tunnel. When ready for concreting the wooden troughs were plugged and the compartment allowed to fill with water. When this was completed the concrete was poured into the still water down the pipe. Shortly after commencing the concreting, water began to discharge through the 2-in. pipe leading through the bulkhead. Finally grout began to appear discoloring the water; then the pipe was closed. Concrete was poured into this hole until it finally appeared in the cave-in previously mentioned above the centre of the tunnel.

Twenty-three holes in all were bored, the total cost of well boring, casings, temporary trestle over river and segregation prevention being less than $2.50 per cubic yard of concrete. Experience indicates that at least one-third of these holes might have been omitted. Where a 60-ft. head is obtainable the holes may be safely spaced at 80 ft. and with a certainty that all of the cavities will be thoroughly filled.—From "Enginering News-Record," New York.

PROTECTING IRON AND STEEL STANDPIPES FROM CORROSION

IN an attempt to bring together such information as may be obtainable, relative to actual experience with standpipe paints, Metcalf & Eddy, consulting engineers, of Boston, Mass., sent inquiries to water works in the northern and eastern parts of the United States where iron or steel standpipes are in use, requesting information as to the dates of painting, kind of paint used, preparation of the surface for painting, and other significant data. In general, the water works superintendents were generous with their responses, which were received during the winter of 1916-17, but in a disappointingly large number of cases the responses were, in effect—"The writer has been here but a short time. The former superintendent left no records and I do not know what paint was used or when it was applied."

The significant data received in response to this inquiry, together with some information available from other sources, were given in a paper read last week by C. W. Sherman, of the firm of Metcalf & Eddy, at the convention of the New England Water Works Association. Mr. Sherman's data cannot be summarized or averaged. In a few cases the standpipe had not been painted since erection. There are doubtless cases in which the quality of the water is such that it protects rather than corrodes the metal; such cases are, however, rare and experience seems to indicate that as a rule an iron or steel standpipe should be thoroughly cleaned and painted inside at least as often as once in four or five years, says Mr. Sherman. Perhaps, however, if the cleaning were as thorough as would be accomplished by means of the sand blast, and if a protective coating where then properly applied, the interval between paintings could be materially extended.

A. H. Kneen, of Philadelphia, painted two standpipes with vertical stripes of different kinds of paint, and observed the conditions after two or three years of service. The only paints which gave reasonably good service were a red oxide of iron paint, and red lead. Most of the paints used were undoubtedly proprietary articles, and although one red oxide of iron paint showed "good" or "very good" results, several others characterized the same way in Mr. Kneen's tabulation gave "bad" or "very bad" results. Red lead when used was employed only in the first coat, yet the results were characterized as "good" or "very good." It is not impossible, therefore, says Mr. Sherman, that two or three coats of red lead would have shown better protection than any of the other paints.

Practical Results Confirm Experiment

Mr. Kneen says: "Under the writer's supervision, we have had the inside of fifteen standpipes painted and repainted in the past seven years, the combined area of which is over 112,000 sq. ft., and the results obtained are similar to those obtained in the experimental tanks. Our conclusion to date is that paints having pitch or asphalt for a base, applied in this manner, are not suitable for iron in contact with water, but that two-coat work with a good quality of iron oxide or a paint with a good red lead base for the first coat, and an iron oxide paint for the second coat, if the iron is properly cleaned and the paint is properly applied, will protect the iron in contact with water for at least four years, unless the water is of unusual quality or the conditions are different than usually met with in water works practice."

The engineers of the Metropolitan Water Works (Boston) have adopted the policy of cleaning the steel by sand blast, and applying three coats of red lead to the interior surface of their steel standpipes. The following quotation from the fifteenth annual report of the Metropolitan Water and Sewerage Board describes the cleaning and painting of the Bellevue Hill standpipe:—

"On March 25th, the tank was taken out of service and drained, and the work of sand blasting and painting the steel was begun March 30th, by the W. L. Waples Co., of Boston, subconstractor for this work. The plant used consisted at first of a twenty horsepower gasoline-engine-driven air compressor, a compressed air reservoir, two lines of air hose and two nozzles. Sand blasting was stopped in the latter part of the afternoon of each day, and the cleaned surfaces were painted before rusting commenced. The force employed included one foreman, two painters, who also did sand blasting, and one helper. This force could sand blast and paint an area of about 330 sq. ft. per day. Later, in order to increase the rate of progress, a second compressor, operated by an automobile engine, was installed on April 19th. The entire inside and outside surface of the tank, having an area of 35,650 sq. ft., was sand blasted and painted. Work was completed June 14th, with the exception of the third coat on the outside, which has been deferred until after the masonry tower which encloses the tank in completed. All painting materials were furnished by the department, but were mixed by the contractor under the direction of the engineer. For the inside of the tank, National Lead Company's red lead in oil paste, litharge, and Spencer-Kellogg & Son's boiled linseed oil, were used; the first coat natural color, the second and third coats tinted with lampblack in oil. For the outside of the tank, red lead paste, raw linseed oil, and drier were used for the first coat, and for the second coat white lead, raw linseed oil, turpentine, and drier tinted with lampblack were used. One gallon of red lead paint was sufficient to cover 700 sq. ft. of surface with one coat. The subcontractor's price for sand blasting and painting the tank was $1,600. . . ."

Paint Immediately After Sand-Blasting

Mr. Sherman inclines to the opinion that the method just quoted represents the best practice of the present time. He would put especial emphasis on the thorough cleaning of the metal, and the *immediate* application of the paint to the cleaned metal before the latter has cooled and moisture has condensed upon it. The following quotation is pertinent in this connection:—

"Every specification for painting bristles with clauses prescribing what shall or shall not be done, and still the fact remains that there are more failures than even indifferent

successes, especially on work painted at the shops before shipment. The causes for the irregular and indifferent results are not difficult to ascertain. They are the improper application of the paint to dirty, greasy, moist or chilled, rusty or mill-scaled surfaces. No marked improvement in these uncertain results can be had until the same importance it attached to the 'paint question,' not only on paper, but in the actual supervision of the painting in all of its stages, as is given to the minutest construction details."

With regard to the coating to be applied to the metal after cleaning, it appears probable that not only red lead, but several of the graphite and red-oxide-of-iron paints, and perhaps certain enamel-like coatings, will give satisfactory protection.

10,000,000-GAL. RESERVOIR AT DAYTON

IN the year 1917-18, a covered masonry reservoir of 10 million gallons capacity was built for the water department of the city of Dayton, Ohio, to equalize the hourly fluctuations in water demand, to facilitate the making of minor repairs at the pumping station, and to provide fire service storage capacity corresponding to the 1916 standard of the National Board of Fire Underwriters. This reservoir was described by Leonard Metcalf and William T. Barnes, both of the firm of Metcalf and Eddy, of Boston, Mass., in a paper read last week at the convention of the New England Water Works Association. Following is Messrs. Metcalf and Barnes' summary of the points covered by their paper:—

The variation in rate of pumping at the main pumping station, to meet the demands of domestic, commercial and industrial water service, was from about 6 million to 35 million U.S. gallons per day. The storage required to equalize the hourly variations was approximately 3 million gallons, or 25% of the average daily water consumption.

The fire supply storage capacity required by the National Board of Fire Underwriters (1916 standard), corresponding to a ten-hour flow at maximum fire demand, was approximately 7 million gallons.

The sum of these two amounts (3 million and 7 million gallons) determined the capacity of the structure, which was reduced to the minimum on account of the difficulty and high cost of construction during war times.

The reservoir was built of concrete with walls of gravity section; inverted groined arch floor with 8-in. crown thickness; and 26-in. reinforced cylindrical concrete columns varying in length from about 20 ft. to 26 ft., supporting a flat-slab concrete roof 8⅜ ins. thick, reinforced with corrugated bars on the two-way system.

The original design prepared by the engineers for this work contemplated the construction of a groined arch floor and roof type of structure, with lighter walls than those finally used. This design was modified, however, on account of war conditions which made it impossible to secure outside bids and on account of the fact that the local bidders were more familiar with and better equipped to build the flat-slab roof construction and were therefore ready to submit relatively lower figures upon this type of construction than upon the groined arch structure. The unusual saving in cost here found justified the acceptance of a type of structure believed to have a somewhat smaller factor of safety and shorter life.

The total cost of the work to the contractor, excluding profit but including the cost of the materials furnished to him by the city, was $126,805, equivalent to $14.50 per cu. yd. of concrete, $12,680 per million gallons of net storage capacity, $2.08 per sq. ft. of net water surface, and $90,600 per acre of net water surface (the water surface being approximately 60,917 sq. ft., or 1.4 acres, and its depth averaging approximately 23.2 ft.).

The total cost to the city, including the land and engineering was approximately $153,041, equivalent to $17.50 per cu. yd. of concrete, $15,300 per million gallons of net water capacity, $2.51 per sq. ft. of water surface, and $109,300 per acre of water surface.

The character of the finished work was excellent, the concrete being dense and reasonably smooth.

The leakage of the finished structure was found to be $2\frac{5}{16}$ ins. vertically, or 88,000 gals. per day; and three months after putting the reservoir into service, 1¼ ins. vertically, or 48,000 gals. per day.

RECENT PUBLICATIONS

LIFE SAVING STATIONS.—An interesting folder calling attention to the fact that typhoid fever and similar intestinal diseases are caused by pollution of water supplies and that sterilization plants are really life saving stations, located not at the seaside but on reservoirs, streams and pipe lines. Issued by the Wallace & Tiernan Co., Inc., 349 Broadway, New York City.

WEBER CHIMNEYS.—Catalogue, 56 pages and cover, 5 by 9 ins., illustrating and describing reinforced concrete chimneys, including a number in Canada. The frontispiece is a photograph of what is claimed to be the highest chimney in the world, designed and erected by the company at Sagancseki, Japan; height 570 ft.; inside diameter at the top, 26 ft. 3 ins.

YARHOLA OIL PIPE LINES.—Description of the oil pipe lines of the Yarhola Pipe Line Co. extending from near Healdton, Oklahoma, to the Wood River Refinery, near St. Louis, Mo. This line is the property of the Roxana Petroleum Co., one of the producing companes of the Royal Dutch-Shell Co. The pipe line was designed and built by Sanderson & Porter, consulting and contracting engineers, New York, who are the publishers of the pamphlet. Illustrated; 18 pages and cover; 8½ by 11 ins.

JEFFREY STRAITFLO VENTILATORS.—Bulletin No. 270 of the Jeffrey Manufacturing Co., Montreal, P.Q., and Columbus, Ohio; 8 pages, 7½ by 10½ ins.; printed in two colors on coated paper, illustrated. This type of fan is equipped with a central disc about half the diameter of the wheel, on which is mounted blades designed so that the expulsion of the air will be the same at all points. It is used for drying or boosting purposes and also for removal of dust, heat and smoke from factories and other buildings.

ST. LAWRENCE RIVER POWER CO.—Interim order of the International Joint Commission in the matter of the application of the St. Lawrence River Power Co. for the approval of the construction and maintenance of a submerged weir in the south channel of the St. Lawrence river near the mouth of its power canal at Massena, N.Y.; 302 pages, folded maps and cover; 6 by 9 ins. The appendix comprises the larger portion of the book, presenting the detailed stenographic report of the evidence taken at the hearings.

HYDRAULIC TURBINE INSTALLATIONS.—New catalogue issued by the S. Morgan Smith Co., York, Pa., and Montreal, P.Q.; 64 pages and cover, 8½ by 11 ins., printed on coated paper in two colors and profusely illustrated. A number of views are shown of the company's various shops and foundries. A brief reference to the importance of runner and case design, and an explanation of type characteristic, together with efficiency contour charts, add to the reference value of the catalogue. The company's governor and pressure regulator are described, also the Gibbs oil thrust bearing, while the construction and erection of hydraulic turbines is described in considerable detail, illustrated by line drawings and half-tone views of numerous installations in Canada and the United States. The half-tones are beautifully printed and are typical of modern hydro-electric developments.

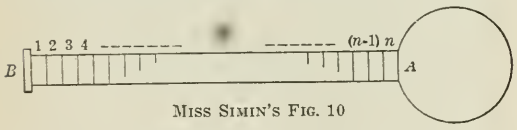
PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSING OF TURBINE GATES*

By Otto V. Kruse
Hydraulic Engineer, Larner-Johnson Valve & Engineering Co., Philadelphia, Pa.

THE writer has studied the phenomena of water-hammer, and offers a short analysis of Miss O. Simin's translation of Prof. Joukovsky's notable work, and an elaboration of certain parts of Mr. Gibson's paper.

Any pipe under pressure and containing water in motion may be assumed as a unit of energy under a condition of equilibrium. If we wish to stop the column of water, it means the application of a certain amount of force during a certain time to bring about the conversion of energy and restore the equilibrium. In analysing the phenomena which take place, the writer believes that the most important point to study is the rate of destruction of velocity as affected by the net head, because this determines to a large extent the rate of pressure rise and hence the maximum pressure rise. Apparently, Allievi used this as a basis for the development of his formula, and this, of course, applies to Johnson's formula, which is the same as Allievi's. Any formulas, such as Warren's and Vensano's, which do not take this into account, must be incorrect, except for one set of conditions. The curves given by Mr. Gibson show how far from the truth they may be.

In accordance with the ordinary methods of integration, it may be considered that the gate movement throughout the duration of the stroke is made up of an infinite number of small instantaneous movements. In the case of the formulas



Miss Simin's Fig. 10

of Allievi and Johnson, which involve the dynamic forces, each little movement of the gate produces a pressure:—

$$h = Ldv/gdt$$

The conditions existing, then, at the end of any small movement are:—

1. The original velocity has been decreased by the amount of the velocity destroyed during this first movement;
2. A dynamic pressure has been created due to the destruction of velocity.

A new velocity now exists, which is dependent, not on the original net head, but on a new head made up of the original net head and the dynamic head. As brought out by Mr. Johnson, these curves of dynamic pressure-rise and decrease in velocity may be calculated by a simple method of arithmetic integration, using only the relation, $h = Ldv/gdt$. The Allievi or Johnson formula will give a figure for maximum pressure rise, and Mr. Johnson has also developed a formula for the shape of the pressure curve, these formulas giving the same results as can be obtained approximately by arithmetic integration.

The question to be considered now is: To what extent, and how, do the compressibility of water and extension of the pipe walls affect the pressure and velocity curves? We know that, as the time of closing grows shorter, the Allievi formula approaches infinity. On the other hand, Joukovsky proved that the maximum pressure which obtained for instantaneous closing depended on the velocity destroyed and the speed of propagation of the pressure wave, and could not exceed "maximum water-hammer." It is not difficult to see that, for a long closing time, the compressibility of the water and extension of the pipe walls have very little effect on the maximum pressure, but, as the time of closing grows shorter, the properties of the materials have a greater and greater effect. The writer believes that Mr. Gibson's formulas have successfully supplied this missing gap between Allievi's and Joukovsky's theories, and serve to give correct results for all conditions.

Professor Joukovsky made a great many experiments to determine the magnitude of maximum water-hammer and the speed of propagation of the pressure wave, all based on instantaneous closing of the gates. The details of the experiments will not be given here, but the following is a synopsis of the theory, taken verbatim from Miss Simin's translation:—

"In Fig. 10, let $A\ B$ be a pipe, in which water flows with velocity, v, from the origin A, past the gate B. If, now, the flow is suddenly stopped by a rapid shutting of the gate, B, the kinetic energy of the water column, $A\ B$, will cause an increase of pressure in the pipe.

"Let us consider the column of water, $A\ B$, as divided into n very small equal sections, 1, 2, 3,.... $(n-1)$ and n.

"The phenomena of water-hammer take place in a series of cycles, each consisting of four processes, as follows:—

"(1) Section 1, meeting, in the gate, an obstacle to its movement, will be compressed and will stretch the pipe wall surrounding it. All the kinetic energy of this section of water will be used up (a) in its own compression, resulting in the increase of pressure by an increment, P, and (b) in the corresponding stretching of the walls in section 1 of the pipe. As a result of this action, section 1 of the water column has left vacant behind itself a small space, to be occupied by a part of the next arriving section 2. Consequently, it is only after section 1 has been stopped and compressed, and after the small space thus left has been filled, that section 2 can be arrested and compressed.

"Now the kinetic energy of section 2 must be expended in some way. Will it increase the pressure upon the gate, which has already been caused by the arrest of section 1? No, and for the following reason:—

"The pressure upon the gate depends entirely upon the pressure, P, sustained by section 1, which is now in static condition.

"The pressure upon the gate could therefore be increased only if section 1 could be farther compressed, and this could take place only if the pressure upon the surface between it and section 2 (which we may imagine to be a thin piston) could be greater from the side of section 2 than it is from the side of section 1; and this is impossible, because section 2 has only the same kinetic energy as section 1, and this energy will (as in the case of section 1) be used up entirely in compressing the water of the section (section 2) only to the same additional pressure, P, and in stretching that part of the walls surrounding section 2.

"The same is true of each following section, 3, 4,.... $(n-1)$ and n; each of these sections, as it is arrested, being compressed to pressure, P.

"During process (1) a small quantity of water flows from the reservoir into the pipe, to occupy the space formed by the compression of the water and the extension of the pipe walls.

"Finally, when all the sections have been arrested, the entire column will be under the pressure, P. The entire energy of the water column is now stored (as potential energy) in elastic deformation—viz., in the compression of the water column and in the extension of the pipe walls.

"But this condition cannot be maintained; for

"(2) As soon as the additional pressure, P, has been produced in the last section, n, the water in that section will again expand, and the walls of that section of the pipe will again contract, restoring the original conditions in that section, and pushing the water of that section back into the reservoir from which the pipe issues, and restoring the original normal pressure in section n.

"The operation will now be repeated by each section $(n-1)$,....4, 3, etc., in turn, until all the potential energy, stored in the water column when it was under the pressure, P (neglecting the portion lost in friction), has been reconverted into kinetic energy.

"During process (2) the water which entered the pipe during process (1) is forced back into the reservoir.

*Discussion (presented to the American Society of Civil Engineers) of Norman R. Gibson's paper (see September 4th and 11th issues of *The Canadian Engineer*).

"The condition of the water column is now what it was just before the gate was closed, except that its velocity, v, has now the opposite direction—i.e., toward the origin.

"(3) The kinetic energy of the water column, moving toward the origin or away from the gate, is now reconverted into potential energy, which manifests itself in an extension of volume of the water to a subnormal pressure beginning with section 1, and concluding only when the entire water column has been reduced to the subnormal pressure.

"During process (3) water continues flowing from the pipe into the reservoir.

"(4) When the subnormal pressure has been established throughout the length of the pipe, and all the water has come to rest, the water from the reservoir will again direct itself into the pipe, restoring the normal pressure, first in section n, next to the reservoir, and then, in rapid succession, in the other sections $(n-1),\ldots.4, 3$, etc., until, when the normal pressure reaches the gate, we have once more the conditions which existed just before the gate was closed—viz., the normal pressure is restored and the water is moving toward the gate with the original velocity, v.

"We have now followed these pulsations of pressure (with the accompanying transformations of energy and flow of water into and back from the pipe) through a complete cycle of four movements, each extending through the length of the pipe. For convenience, we may consider two successive movements of this kind as a 'round trip' through the pipe.

"The gate remaining closed, the whole process is now repeated in a second cycle, which, in turn, is followed by a third, and so on, the amplitude of the pressure vibrations gradually diminishing (because of friction) until the pipe and the water come to a state of rest.

"But although the intensity of the pressure becomes gradually less, the time required for each cycle remains constant for all repetitions.

"This propagation of pressure, consisting of its transmission through all points of the length of the pipe, each point successively repeating the same periodical movements is, in its nature, simply a case of wave motion, like that of a sound wave.

"The velocity of wave propagation is independent of the intensity of the pressure, and depends only upon the properties of the medium through which the propagation takes place—in the case of water-hammer, upon the elasticity of the water and of the pipe."

Mr. Gibson has applied this theory to slow-closing gates by considering that each infinitesimal movement of the gate is instantaneous and produces a small rise of pressure which travels through the penstock in the same manner that a wave produced by total instantaneous closing would travel. These small gate movements occur in succession and produce in turn their pressure waves which travel back and forth through the penstock. An algebraic sum of these waves gives the rise of pressure existing at any time during the closing stroke.

The writer is of the opinion that the pressure existing throughout the length of the pipe for a slow-closing gate varies almost directly from a maximum at the gate to zero at the point of relief, except where the time of closing is less than $2L/a$.

In Fig. 11, the pressure existing at four points on the penstock has been plotted. The magnitude of the individual pressure waves is not to scale, but their values are shown for the particular example taken. The pressure existing at a point $L/2$ from the gate is approximately one-half the pressure existing at the gate. The pressure existing at a point $3L/4$ from the gate is approximately one-quarter of the pressure existing at the gate.

The diagram showing the pressure existing at the point of relief consists of a series of instantaneous rises above normal. On account of the assumption of twelve instantaneous movements of the gate, the pressure at the point of relief must of necessity show twelve instantaneous rises of pressure, as each wave travels undiminished to the point of relief. If twenty-four instantaneous movements were chosen, there would appear twenty-four instantaneous rises of pressure in the same time, but of only about half the magnitude. Hence, in the limit of an infinite number of instantaneous movements of the gate, or uniform slow-closing, the pressure at the point of relief becomes zero. This must be true, because the duration of time of any rise of pressure at the point of relief is zero. Wherever rises of pressure have actually been recorded at the point of relief on a penstock, they are probably due to an instantaneous movement of the gate during the stroke, or to some other cause, such as a sudden elastic deformation of the waterway, which would have the same effect.

In the translation of Professor Joukovsky's work there are shown tables of pressure rises at different points on the pipes for different velocities destroyed. In every case the pressure waves travel practically undiminished almost to the point of relief. The readings taken at the station nearest the point of relief, however, show a reduction in pressure of from 60% to 80%. This is very significant to the writer, as an indication that the pressure travelled undiminished to a certain point and then gradually was reduced to zero at the point of relief. Although Professor Joukovsky experimented with very rapidly closing gates, as nearly instantaneous as possible, obviously a certain fraction of a second must elapse while the gate is closing. When the time of closing is less than one interval, $2L/a$, the resultant pressure will travel undiminished to a point which is $Ta/2$, in feet, from the

point of relief (where T is equal to the closing time, in seconds). From this point it will gradually be reduced to zero at the point of relief. Granting that some short period of time must elapse during the closing of the gates in Professor Joukovsky's experiments, his actual pressure readings seem to verify the writer's claim.

In the example taken, the duration of closure is assumed to be three intervals. The diagrams and curves have been plotted beyond the three intervals to show the fluctuations of pressure which take place after the gates are closed. Experiments should show that the subsequent fluctuations after the gates are closed are quickly reduced in intensity by internal friction, but this friction should have no effect on the speed of propagation of the pressure waves. Internal friction has of necessity been omitted in these computations, as it is an unknown quantity.

Any other example than that shown by Fig. 11 may be chosen, and the pressure waves may be computed by Mr. Gibson's formulas. A series of diagrams may then be plotted, similar to those shown by the writer, and the pressures may be computed for any point on the penstock.

In making the computations for the magnitude of the pressure waves, it is necessary to determine first the number of intervals of time (equal to $2L/a$) contained in the total closing time. The gate movement may then be divided into a number of instantaneous movements equal to the number of intervals. Computations carried out on this basis will give correct points on the pressure-rise curve at the end of each interval. In the event of the closing time being only a few intervals, it is desirable to subdivide the gate movement further in order to develop the curve during the in-

tervals. It is an interesting fact, however, that such further subdivision of gate movement serves only to develop the shape of the curve during the intervals, and has no effect on the values at the end of each interval. In making studies of this character, it is often easier instead of using Mr. Gibson's formulas, to utilize the system of arithmetic integration, which will give correct results, although involving trial-and-error methods.

In order to compute the pressure-rise curve at points on the penstock other than at the gate, the gate movement must be divided into a number of divisions sufficient to cause the pressure waves to overlap. Thus, at least two divisions per interval must be used to compute the curve at a point half way up the penstock, at least four divisions per interval for a point three-quarters of the way up the penstock, and at least eight divisions per interval for a point seven-eighths of the way up the penstock. Referring to Fig. 11, where four divisions per interval were chosen, it is obvious that the pressure beyond the point, $3L/4$ from the gate, cannot be computed without a greater subdivision of the gate movement.

In this discussion the writer has endeavored, principally, to point out the trend of argument and application of existing data used in proving the theoretic correctness of Mr. Gibson's method of handling water-hammer problems. The method seems to be fundamentally sound, and deserves the careful thought of engineers.

PROPOSED TIDAL POWER DEVELOPMENT AT HOPEWELL

(Continued from page 366)

up the matter of borings with the provincial government very urgently last winter, but I was met at first with promises, and later with apathy, and I regret I could not undertake the expense of the matter personally. This summer I went twice to Hopewell, but could only obtain indirect evidence as to the depth of the rock under the muddy beds of the two rivers. The full line of the profile shows the depth of the top of the mud according to the admiralty chart, and there is strong presumptive evidence that the top of the rock does not lie more than 15 to 20 ft. below this. Where the "new wharf" was built at Hopewell, the mud soon washed out for a depth of 12 ft., when hard bottom was reached, and the outcropping of ledge rock at the mouth of the Memramcook indicates that rock bottom for a quarter of a mile is very near the surface. The shores at Hopewell, Fort Folly Point and Cole's Head are all rocky, and the nature of all rock in this locality is the same, viz., shaley sandstone to pure sandstone, sufficiently sound for making grindstones.

As to the best type of dam to build at Hopewell, I feel that I should offer no opinion, for the question of dam design is an engineering specialty and only an expert in this particular branch of engineering could decide the best type to adopt, and he only after a systematic line of borings were obtained along the proposed site. It has been suggested to me that a dam composed of hollow sections of concrete is a satisfactory and cheap type to build, the sections being built in a dry dock, floated into position and then sunk by filling the interior with rock and gravel. However, I doubt if this is a well proven system and, as I say, the question of best type should be decided by an expert of long experience.

Such estimates of cost that I have been able to make have been based on the cyclopean concrete type of dam. In considering the best type to build at Hopewell, the question of the tidal currents would have to be considered, and while these currents are not very swift, when the great height of the tide is considered, nevertheless they should receive attention. Fig. 4 shows some current measurements that I made this summer by using a ship's log attached to an anchored boat. When the tidal range was 38 ft., the channel current reached a maximum of 4.2 knots and you will note that although the flood current soon dies out, the ebb persists at near its maximum until almost the time for the next flood tide to begin. Out of the channel the current runs swiftly for much shorter periods, and the tidal current makes shoreward as the shores are approached, until we often have currents at right angles to the main stream. The dotted curve shows some measurements taken rather off the channel, with a tidal range of 28 ft., and the maximum under these conditions was 2.6 knots.

Before leaving the engineering problems that are presented by this novel plant, I will refer to three other items that should be considered.

The question of subnormal neap tides requires especial attention, for while my calculations are based on the least range, viz., 32 ft., of ordinary neap tides, nevertheless there are certain tides which occur sometimes three days a month, sometimes five days a month, and sometimes not at all in a month, which have a lower range than 32 ft., and may sometimes have a range as low as 24 to 25 ft.

Subnormal Neap Tides

Now, if our plant were built and running at full capacity, with a range of 32 ft., there would be an impairment of the regular capacity whenever these subnormal neaps occurred (which is about 15% of the time), and I think some provisions should be made to deal with them adequately.

One method might be to keep the turbines and generators well ahead of the normal demand and use these extra ones only during the subnormal neaps. Another method would be to keep the Memramcook shovelled out (as already described) well ahead of the regular requirements, and thus improve the average head. Yet another method would be to build a freshwater dam (say just below Turtle creek, about 5 miles west of Moncton) in which freshwater would be impounded and released only to make up the deficiency in head at subnormal neaps. Still another method would be to employ auxiliary steam power to assist the water-power during the water deficiency. One of the last two devices is nearly always resorted to in the case of ordinary hydro-electric plants situated on fresh water rivers. In nearly all districts the amount of rainfall varies enormously during the different months of the year, and the amount of run-off and discharge varies in a direct relation to the rainfall. As an example of this, the discharge at Grand Falls on the St. John river reached a maximum in May, 1909, 50 times greater than the maximum of October, 1900, and the mean discharge for the whole month of May was 20 times greater than the mean for October. In fresh water rivers a certain power may run into thousands of hosepower in the spring, but be reduced to hundreds in the fall of the year unless adequate means are resorted to in order to increase the deficiency of head.

In this matter, a tidal power scores heavily over a freshwater power. In the case of the freshwater power, neither the time nor quantity of head deficiency can be predicted, but with a tidal power, both the amount and the deficiency are predicted by the tide tables several years in advance, and it will thus be much easier to provide for our head deficiency, which only, after all, amounts to 25% in quantity and occurs only 15% of the total time.

The best means of making up the deficit in the case of the Hopewell Tidal plant would be best figured out in the final estimates as that one which would maintain the normal output at a minimum of cost.

Sediment and Ice

The two other remaining engineering items are sediment and ice. At present the never-ceasing current flows up and down the two rivers, keeps the river mud stirred up, and the water of both rivers shows a considerable amount of sediment, and one would at first jump to the conclusion that this muddy grit (fine though it is) would produce much unusual wear on the turbines. However, what will happen as soon as the mouth of the Petitcodiac is closed by a dam? The mud in the water above the dam will undoubtedly settle, for it will have time to do so, and the water of the Petitcodiac will become clear. At present the water is never still, but with a dam, the rise and fall would be reduced to a few feet and the current would be sluggish.

In a similar way, the building of the dam would entirely alter the ice conditions. Once the dam was built, the whole

river would freeze over in severe weather, and the sheet of ice would rise and fall with the water just as it does in the St. John and similar rivers. Nevertheless, while the building of the dam was in progress, the question of large masses of ice moving with the current should be given every attention, and quite likely some special method of cushioning the blows from ice might have to be devised.

Considering the method of distributing the power available at Hopewell, Fig. 7, shows how centrally Hopewell is placed with reference to the centres of population of both New Brunswick and Nova Scotia.

The method of transmission carries with it no special problems, as we would undoubtedly use step-up transformers at the power house, transmit at about 30,000 volts with 3-phase current, and use step-down transformers at the delivery points. All this system has been so thoroughly thrashed out, and is in daily use all over Canada and under Canadian winter conditions, that it has become practically standard and needs no special consideration here.

Population and Power Requirements

The principal feature that should be considered in laying out the transmission lines would be one of expediency and proper return on the capital outlay of transmission lines and line losses. Undoubtedly, a main line should go west to St. John, with power for all intervening towns and villages of any size, and undoubtedly a main line should go east and south to Halifax with power for Sackville, Springhill, Amherst, Truro, etc., and also branch lines should go to Moncton, New Glasgow and Stellarton, as the present population would warrant this. The extension of branch lines to St. Stephen, Fredericton, Newcastle and Chatham is somewhat doubtful at present, but there are railways that well might be economically electrified toward all these points, and I have therefore included them in the preliminary estimate. I have prepared a table of the population that would be served by these lines, and the total works out at 250,000 inhabitants. With this as a basis we should now estimate the probable per capita use and thus obtain an estimate of the proper size of plant for the initial development at Hopewell.

When I prepared my first report on this subject, it was submitted to the well-known firm of Sanderson & Porter, of New York, a firm who specialize in the control and management of some 60 hydro-electric developments, and their condensed criticism was as follows:—

"We think your proposal from an engineering standpoint is sound and it is the only scheme for utilizing tidal power that seems practical, but we are rather in doubt as to whether the population served is sufficiently large to warrant the capital expenditure."

Now this was in 1914, and I presume Sanderson & Porter based their opinion on the per capita use of hydro-electric power in the United States, which works out at 0.10 h.p. per inhabitant, according to their text books. On this early report, and on their opinion, I based the letters to the newspapers that were published in St. John and Halifax, and in these letters I appealed for governmental help, since it seemed at that time that while my proposal was almost a commercial one, it was not conclusively so.

0.36 H.P. per Capita

Since last January, however, newer data has come to hand, and this data is accurate, as I presume it is, the complexion of affairs has changed and the Hopewell plant is really a good commercial proposition at the present time, and needs only the governmental help accorded by a good charter.

The data that I speak of shows the per capita use of hydro-electric power for every province of Canada and for the Dominion as a whole. It shows that British Columbia uses 0.36 h.p. per capita, Ontario 0.288, Quebec 0.267, and the whole of Canada 0.206 h.p., and these figures are for the total population and they should be increased at least 30% for the per capita use of population served. It will thus be seen that Ontario, per capita served, is using about 0.37 h.p. and Quebec about 0.35 h.p., and I think we may properly assume that 0.36 h.p. would be used by the inhabitant of the Maritime Provinces as soon as he is given really cheap electricity.

On this basis, then, the population of 250,000 would require 90,000 gross horse-power, or, say, 45,000 h.p. at the delivery points, and I think the initial development at Hopewell should be for 90,000 h.p., with every provision made for increasing the output, as already outlined in this paper, up to 200,000 gross horse-power as the population and demand increased, as they undoubtedly would when cheap power was available.

Cost of Initial Development

Turning to the question of costs, I have made an estimate of this as follows, and in accordance with the text books on the subject:—

DAM COST IN CYCLOPEAN CONCRETE

Western Dam.	
730 lineal feet at equivalent height of 38 ft. and $137 per lineal foot	$ 97,000
4,100 lineal feet at equivalent height of 65 ft. and $300 per lineal foot	1,230,000
Eastern Dam.	
2,800 lineal feet at equivalent height of 65 ft. and $300 per lineal foot	840,000
2,000 lineal feet at equivalent height of 35 ft. and $120 per lineal foot	240,000
Wing Dam.	
900 lineal feet at equivalent height of 30 ft. and $94 per lineal foot	84,600
10,530 ft. Total cost,	$2,491,600

One well-known engineer who examined my first report, considered this too low a figure and thought $4,000,000 should be allowed for dams, and since we will remain uncertain about the dam cost, until borings are made, it will be best to allow this higher figure in the preliminary estimates.

The other items of cost can be more accurately estimated from the known cost of equipment in existing hydro-electric developments, and we have the following table of total estimated cost:—

Dams	$ 4,000,000
Lock in western dam	100,000
Sluices, gates, etc.	300,000
Power house of steel and concrete	200,000
Turbines, generators, etc., at $40 per gross h.p.	3,600,000
Transmission lines, etc.,	1,200,000
Preliminary dredging, dam, trench, etc.	100,000
Promotion, engineering fees, etc.	500,000
Auxiliary plant to supply head deficiency at sub-normal neap tides, say	1,000,000
Total cost of initial development to produce 90,000 gross h.p.	$11,000,000
Or cost per h.p. developed	$ 122.50

Cost of Subsequent Enlargement

The cost for subsequent development is much less, relatively, for in the initial development full allowance has had to be made for the final development in all items except turbines, generators and transmission lines, and the cost of a full development of 200,000 gross h.p. would work out at about $16,000,000, or $80 per gross h.p. In this estimate for final development, the cost of shovelling and dredging the Memramcook farming lands (which would be necessary as previously shown) is not figured, for it would be undoubtedly good policy to start this work as soon as the power house was in operation, and take the necessary cost out of the annual income.

In considering the charge that could probably be made to the consumer initially, we must consider the cost of steam power to the provinces, and I have it on good authority that the actual cost to the largest producers of electricity, by steam, was $60 per h.p.-year before the war, and would be about $90 per h.p.-year at the present time.

Suppose, now, we were to charge half this rate on the average, and place our charge at $45 per h.p.-year, this would

be the average charge and the charge in special cases would work out about as follows:—

	Charge per k.w.h.
(1) To power users in excess of 1,000 k.w.h. per month and 24-hr. service	0.75c.
(2) To power users, in excess of 1,000 k.w.h. per month, and 10-hr. service	1.5 c.
(3) To small power users and 10-hr. a day service	2.25c.
(4) To power users, irregular service	3.0 c.
(5) To small lighting service	4.0 c.

These rates are from one-quarter to one-tenth the rates now charged in the Maritime Provinces. They would attract population and develop industries, and they could be gradually reduced, as the demand for greater output increased the size of the plant, to about 60% of these rates.

On this basis, then, the annual income should be $2,025,000 initially, and this would probably be apportioned about as follows:—

Depreciation and operating expenses at 60% on cost	$ 660,000
Royalty on patent rights at 50 cents per gross h.p. produced	45,000
Enlarging Memramcook valley by shovelling and dredging, the power being supplied by the plant itself, say	200,000
Incidentals	20,000
Interest on capital expenditure at 10% of cost	1,100,000
Total	$2,025,000

While $45 per h.p.-year would probably have to be the initial average charge, as time goes on and the output increases to the full available horse-power, it would be quite possible to reduce the average charge per horse-power-year to $27, without decreasing the rate of 10% per annum on invested capital. This is figured as before, as follows:—

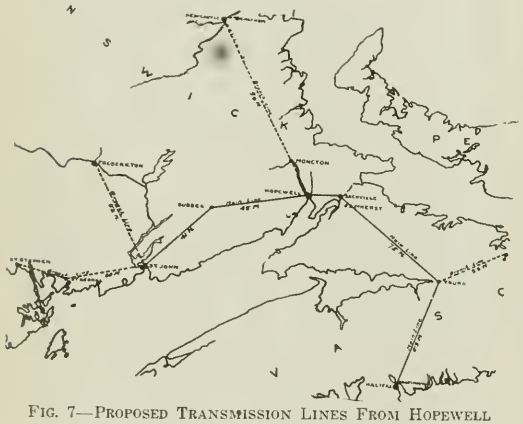

FIG. 7—PROPOSED TRANSMISSION LINES FROM HOPEWELL

For gross output of 200,000 h.p., delivered h.p. 100,000, cost of development	$16,000,000
Annual income from 100,000 h.p. at $27 per h.p.-year	2,700,000
This income is apportioned as follows:—	
Depreciation and operating expenses at 6% on cost	$ 960,000
Royalty on patent rights at 50% per gross h.p. produced	100,000
Enlarging Memramcook valley, nil, since work would by this time be completed	.....
Incidentals	40,000
Interest on capital expenditure at 10% on cost	1,600,000
Total	$2,700,000

The Commission of Conservation's book on the "Water-Powers of Canada" (1911) says, in speaking of New Brunswick, that "the larger rivers, for the most part, are long and their fall is gradual"; and again, that "there are comparatively few lakes in the upper portions of the watersheds of the majority of the rivers and, hence, little facility is afforded for the natural storage of waters for the purpose of equalizing the flow during the low-water periods."

This is true of New Brunswick and it is also true of Nova Scotia. The upper provinces are steadily forging ahead of us, both industrially and in population, and this advance can be ascribed largely to their abundant water-powers, and it behooves us of the lower provinces not to mourn our loss of power, but to make full use of that great power that nature has really placed at our door—viz., the Bay of Fundy tides.

Were we to harness the power that is daily wasted in the two great eastern arms of this bay, we could have the use of 3,500,000 h.p., but this is a dream for the future and is not a practical proposition for to-day. The theory is the same as for the Hopewell plant, but the execution and cost would be impossible at present.

The Hopewell plant is to-day a good commercial proposition. Special engineering problems are attached to it, but they are only those that attach to any special plant. The difficulties are small in comparison to many recent engineering works that have been successful.

NEW ENGLAND WATER WORKS CONVENTION

MEMBERS of the New England Water Works Association met in Albany, N.Y., last week for their 38th annual convention, which occupied the four days, September 30th to October 3rd, inclusive. They were welcomed to Albany by that city's chief executive, Hon. James R. Watt, who is an engineer and contractor.

The presidential address of Samuel E. Killam laid stress upon the opportunities that exist for the association to exert a helpful influence in public affairs. Particular vigilance is needed, he said, in the matter of legislation affecting public health, and in each state a committee should be appointed to examine proposed legislation of this nature.

Over 300 members, associate members and guests were at the convention. The sessions were all well attended, and much interesting discussion followed the papers. The list of papers presented was published in *The Canadian Engineer*, September 25th issue.

The only paper on Canadian work was by Norman J. Howard, who described the construction and operation of Toronto's drifting sand filtration plant. This paper was discussed in a lively manner for more than an hour. James M. Caird, consulting chemist, took a leading part in the discussion. Mr. Caird particularly inquired regarding costs of operation and the ability of the plant to prevent the passage of alum into the filtered water.

Mr. Howard stated that cost figures are not yet available. As to the alum, he reported the presence of aluminum hydrate in the filtered water, but claimed that its presence is not significant, and that so far as he has been able to ascertain, it can be found in the effluent of all mechanical filtration plants, and that it is entirely harmless and inert.

Mr. Caird differed with Mr. Howard in this regard, but several of the consulting engineers and water works superintendents who were present supported Mr. Howard's statements, and considerable difference of opinion was expressed in regard to the point.

Morris Knowles characterized the Toronto plant as a radical departure in water works purification practice, and said that engineers are awaiting with great interest further detailed data on filtration costs.

All of the members and guests assembled on a Hudson River Line steamer on Wednesday, October 1st, and spent the entire day on the steamer, holding sessions during a trip down the river.

A number of the engineers enjoyed an automobile trip Thursday morning to the Gurley factory at Troy, where the Gurley long-distance water recorder was seen in actual operation.

PROPORTIONING OF CONCRETE MATERIALS

ENGINEERS and scientific investigators are delving deep in an effort to discover the fundamentals underlying the assembling and combining of the component materials of concrete; the relation of each of these materials to the strength and other physical properties of the final mass; and the effect of various conditions of placing, curing, etc., tending to influence the permanence of structures in which concrete is used.

The old adage that there is an adequate cause for every effect, and, conversely, an effect for every possible combination or condition, holds especially true of concrete. From the investigations to determine the why and how of all things pertaining to the subject, we have learned that concrete is not a complicated material but that far more care must be exercised in its use than we believed to be the case only a few years ago.

It has been proved that some of the practices now in common use are productive of very widely varying results. Of these, the arbitrary proportioning of the cement and aggregates by gross volumes is now claimed to be especially unscientific.

In this issue is published a discussion, by L. N. Edwards, formerly supervising engineer of bridges of the city of Toronto, of the paper, "Studies in Surface Area Proportioning Method," by R. B. Young, assistant laboratory engineer of the Hydro-Electric Power Commission of Ontario. Mr. Young's paper was first published in our issue of June 26th, 1919.

In the laboratory testing of concrete and concrete materials, no detail is of greater importance than that of securing a uniformly strong cement matrix binding together the particles of the sand and stone aggregates. In specifications for concrete construction work, no detail has been described so indefinitely. No ingredient of the mix performs a more important role than does the water content. It is, therefore, of special interest to note that Mr. Edwards strongly advocates the use, in both laboratory and field, of a method whereby the quantity of water to be used in the mix is mathematically determined. In this connection, it is his contention that the property commonly termed workability, flowability or plasticity, is a secondary factor rather than a primary one, and that it is largely dependent upon the character of the aggregates and the richness of the concrete mix.

In the issue of May 15th, 1919, we published an article, "Bulking Effect of Moisture in Sands," written by Mr. Edwards and containing a part of the results obtained from his tests which were at that time in progress. The more complete information secured from these tests, and more especially the relation existing between the area-water content and the bulking effect, described fully in his discussion of Mr. Young's paper, is well worth serious study, inasmuch as this bulking effect of moisture in sands may have some bearing upon the consistency formula proposed for use in testing concrete and concrete materials.

OUR GREATEST NATIONAL MENACE

IN past issues we have frequently referred to the seriousness of Canada's fuel problem. In this connection, in last week's issue, there was published the clearly expressed and statesmanlike address delivered by Arthur V. White, consulting engineer of the Commission of Conservation, at the annual meeting of the Canadian Gas Association. In view of the industrial and economic situation in Canada, we unreservedly agree with Mr. White in his statement that "whether conditions of curtailed fuel supply for Canada be delayed from materializing this coming winter or next winter, or until some time in the future, nevertheless I am firmly convinced that there is no menace to Canada's economic and general welfare at all comparable to the fact that she is at present so largely dependent upon a foreign country for her fuel needs. Without this foreign supply, Canada most assuredly would be put to desperate straits."

In other articles by Mr. White and many other writers, statistics have been given relating to the coal, oil and water power resources of the Dominion. The extent of the development of these resources has been shown; and the lines along which further development and conservation must be expected, have been indicated. If these various phases of the subject are not co-ordinated by some agency sufficiently powerful to take the fuel problem seriously in hand, such as a federal ministry of fuel, we may some day have "Fuelless Months" instead of "Fuelless Mondays."

It is idle to talk about the great natural resources of Canada unless those resources are to be actively developed. As Mr. White says:—"I shall not dwell on these enormous reserves. It seems out of place to emphasize how much we have latent when alongside of it we are not able to show how beneficially these assets are being used both for our own support and for the assistance of other needy nations. When the population of the prairie provinces are insured against yearly fuel shortage, we shall be more interested in hearing emphasis laid upon the enormous fuel reserves of these provinces; and when Canada produces more than her present amount of 2 per cent. of her total annual oil consumption, we shall be more interested in hearing emphasis placed upon the statement that we have the biggest oil fields in the world."

Canada's only sane policy is to develop as rapidly as possible both her fuel and power resources, and by co-ordination of transportation and other cognate agencies, to provide for the distribution and storage of fuel in all communities of the Dominion. As Mr. White says, in some respects it is more important to move coal and have it adequately stored and distributed throughout Canada, than it is to remove grain out of the country.

PERSONALS

Carleton Emerson Davis, who will preside at the convention of the American Water Works Association to be held next summer in Montreal, Que., is chief of the Bureau of Water, Philadelphia, Pa. He graduated in 1893 at the Massachusetts Institute of Technology. After graduation he was assistant engineer at Manchester, N. H., for one year, and then spent four years as assistant engineer on the construction of extensions to the water works at New Bedford, Mass. After several years as resident engineer on the construction of additional water facilities for Newark, N. J., Mr. Davis was chosen as engineer in charge of water works, sewers and municipal engineering for the Isthmian Canal Commission, Panama. In 1905, he was engaged by J. Waldo Smith, chief engineer of the Board of Water Supply, New York City, as head of the reservoir department in that city, which position he occupied until 1912, when he resigned to accept his present post at Philadelphia, which includes operation and maintenance as well as the assessment of revenues aggregating $5,500,000 per annum. Mr. Davis has also charge of all extensions and improvements to the Philadelphia water works. He was elected president of the American Water Works Association last June at the meeting held in Buffalo, N.Y. For the past twenty years he has been a member of the American Society of Civil Engineers.

A. Frank Wickson, of Toronto, has been elected president of the Royal Architectural Institute of Canada for the next twelve months. Alcide Chausse, of Montreal, was re-elected as honorary secretary.

C. D. Harrington has been appointed vice-president and manager of Anglin-Norcross, Ltd., a recent amalgamation of two large construction companies in Montreal. Mr. Harrington is an engineering graduate of McGill University.

H. T. Routly, construction engineer of the Ontario Department of Highways, has resigned. It is stated that Mr. Routly tendered his resignation last July, but it was not accepted until October 1st. The duties of his office are being apportioned among the other members of the department's staff.

Letter to the Editor

QUANTITY SURVEYS vs. "PAYMENT"

Sir,—I notice in your issue of September 18th, an article outlining the "Kelley System" of payment to contractors for estimating. I have studied the so-called "Nelson" and "Kelley" plans, and although I may be somewhat dull, I cannot for the life of me understand how either plan could be proposed to take the place of the quantity surveyor.

At the present time, engineers and contractors are trying to get away from conditions that they recognize are unfavorable both to the profession and to the owners who have to pay for the work. The cost of living has in some way to be brought down from its present high level, and, owing to the high wages existing, it seems to me that the only way in which we can reduce the cost of building is to eliminate so far as possible these bad conditions,—eliminate the unnecessary duplication of our work and create efficiency in every department.

Following this argument it seems that the first bad feature to be eliminated is the taking off of quantities by each contractor and having this done by a competent man who specializes in this work, issuing plans, specifications and bills of quantities complete to each contractor tendering.

By introducing the quantity surveyor, every contractor figures on the same bill of quantities. We thereby eliminate the excessive cost of taking off the quantities by having *one man do the work once*, and not a dozen times or more according to the number of contractors figuring. It is very easy to be seen that every contractor figures (in his overhead charges) the cost of taking off quantities and estimating work which he never obtains. Therefore, those who pay for the work executed, also pay for the work which the contractor has done on other tenders of which he did not receive the contract. So, by introducing the quantity surveyor, we eliminate the duplication of work, and also lower the cost of such work to the owners.

Why should Mr. Kelley receive 7½% commission from the contractors? Why should the local agent receive 7½% commission? It seems to me that this system is what might be called, in somewhat slangy language, a "skin game," and, as far as I can see, would by no means tend to raise the status of the contractors in the estimation of the engineers and owners.

In the past many people have looked upon a contractor as almost a crook, and it is undoubtedly a fact that many men who are to-day in the contracting business are better equipped for other spheres of operation rather than the contracting business, and it seems to me that this so-called "Kelley" system would bring into operation many more men of that description.

The contracting business to-day is every bit as much of a profession as is engineering, and it is up to the contractors and engineers to wake up and put themselves in a position where they can claim the respect and admiration of the community. This cannot be attained by any easy-money scheme, such as the "Kelley" plan, to my mind, is liable to become.

The article in question makes no distinction between "taking off the quantities" and the "estimate of cost." We cannot eliminate the cost to the contractor of *estimating*, for he is the only man who can estimate the cost of his work, and this is absolutely a part of his business.

Quantity surveying, however, is a very intricate and necessary branch of the civil engineering profession, and we all know that work done by a man who specializes in any particular line is far better than that done by a "Jack-of-all-trades."

The whole of the questions in the "questionnaire" seem to point to the fact that the whole system is designed as a method of getting easy money and should not be recognized by any contractor, engineer or architect, it being detrimental to the profession in every way.

We can go just as far as we like along the lines of the "Nelson" and "Kelley" plans and never get anywhere but in bad repute with the public. Each plan proposes payment of money for work done which *is absolutely unnecessary work*, and the sooner we come to recognize the fact that the quantity surveyor is absolutely the one and only answer to the question, the the better it will be for the profession.

I think that all those in the engineering and architectural professions will soon see that it is to their advantage to insist on the quantity survey being put into general operation, and the societies of the professions to insist that a bill of quantities be issued together with the plans and specifications.

EDW. H. BECK,
Chief Engineer,
The Lake Huron Steel Corporation, Ltd.
Goderich, Ont., October 2nd, 1919.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Assiniboia, Man.—Town council has made application to the Public Utilities Commission for a new subway under the C.N.R. and G.T.R. tracks.

Barrie, Ont.—Town council contemplates paving program for the main business streets, construction to commence next year.

Cumberland, B.C.—The department, of public works Victoria, contemplate repairs or construction of the road to Comox Lake, a direct road to Merville and the Royston-Qualicum road. Dr. J. H. King, minister.

Golden, B.C.—The building of a road from Golden to Leanchoil was urged upon Major A. W. Gray, chief engineer of highways, Dominion parks branch, at a meeting of the Golden Board of Trade, held recently.

Hamilton, Ont.—The suburban area commission have taken over the following roads: Road No. 1, Dundas and Waterloo, from the w. limits of Dundas to town line between Beverley and West Flamboro; road No. 7, Port Flamboro, from Toronto-Hamilton highway to water front; road No. 8, Waterdown Rd., continuing from the present terminus to Carlisle; road No. 11, Mt. Albion, continuing from the present terminus to Long's Corners; road No. 24, Barton St., continuing from the present terminus to intersection of road No. 23, known as the Burlington and Stoney Creek road; road No. 28, Garth St., from the Beckett drive to road allowance between concessions 5 and 6, thence w. to the sanatorium, and west to the Caledonia Rd. These roads will be maintained jointly by the city and county, each paying 30 per cent. of construction and 40 per cent. of maintenance, and the government, which pays 40 per cent. of construction and 20 per cent. of maintenance. T. J. Mahony, chairman.

Havelock, Ont.—The department of public works, Ontario, has authorized construction of road from Havelock to Trent river. Construction will probably commence this fall. W. A. McLean, deputy minister.

Hawkesbury, Ont.—Town council intends to construct a 5-ft. cement pavement along the south side of Regent St. Estimated cost, $2,600. Clerk, Eug. Paquette.

Kingston, Ont.—City council contemplates construction of pavement on Montreal St., to be laid in 1920.

Montreal, Que.—Contract has been awarded by the civic commission for rebuilding the Cote des Neiges Rd. to the Sicily Asphaltum Repairing Co. Contract price, $127,027.

Montreal, Que.—The contract for paving Notre Dame St. West, from Chaboillez Sq. to Dominion St., has been awarded by the Administrative Commission to the Sicily Asphaltum Paving Co., the lowest tenderer, for the sum of $41,756.

Peterborough, Ont.—Council contemplates construction of a temporary pile bridge, 22 ft. in width, to cross the river close to the Hunter St. bridge. The cost, which is estimated by C. J. Townsend, superintendent for the Russell-Townsend Co., bridge contractors, to be $4,970, will, it is understood, be borne by the contractors, and be included in the original contract for the Hunter St. bridge.

Pittsburgh Tp., Ont.—Tenders will be received by W. A. McLean, Deputy Minister of Highways, Parliament buildings, Toronto, until 12 o'clock noon on Tuesday, October 14th, 1919, for the construction of the concrete structures on the provincial highway in the township of Pittsburgh. Plans and specifications may be seen at the office of the City Engineer, Gananoque, Ont., and at the office of W. A. McLean.

Shellmouth, Man.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Tuesday, October 21st, 1919, for the renewing of floor of Shellmouth Bridge. Plans may be seen and specification obtained at the Department of Public Works, Ottawa; at the office of the District Engineer, Winnipeg, Man., and at the post-office, Shellmouth, Man.

Vancouver, B.C.—Contract has been awarded by the board of control for new guard pier at the Granville St. bridge to E. J. Ryan Contracting Co. Contract price, $12,283.30. Rejected tender, W. Greenlees, $13,356. Contract for class "B," which includes creosoting part of the superstructure, was also awarded to the E. J. Ryan Contracting Co. Contract price, $19,520.10. Rejected tender from Campbell and Shook, who tendered on class "A" work, which included creosoting all of the superstructure. Engineer, Mr. Fellowes.

Vancouver, B.C.—The ratepayers defeated the by-law to provide $110,000 for street and roadwork.

Winnipeg, Man.—Authorization for the construction of 277 miles of roads under the Good Roads Board was announced recently. The cost is $676,000. This brings the total mileage up to 3,758 miles at a cost of about $8,219,000.

Winnipeg, Man.—City council intends to construct a 24-ft. asphalt pavement on macadam base on River Ave., from Main St. to Osborne St. Estimated cost, $43,237. City clerk, C. J. Brown.

Winnipeg, Man.—City council intends to extend the boulevard on both sides of River Ave., from Main St. to Osborne St. Estimated cost, $3,000.

WATER, SEWAGE AND REFUSE

Assiniboia, Man.—Town council awarded contracts for sewer and water mains on several streets in St. James, and the necessary pipes, hydrants, valves and other materials, to T. Jackson and Sons, A. W. Green, T. E. Moen, The Canadian Foundries and C. C. Chown.

Chatham, Ont.—The Water Commissioners decided to have an 8-in. main laid from Park St. to the factory of the Dowsley Spring and Axle Co., along Foster St. and St. Patrick St. Four hydrants will be installed. Estimated cost, $5,559.

Deacon, Man.—W. G. Chace, chief engineer of the Greater Winnipeg Water District, has recommended the construction of a 250,000,000-gallon reservoir here as soon as possible.

Hamilton, Ont.—Dr. J. Roberts, medical health officer, city of Hamilton, will request council to purchase the chlorinating plant recently in use at the aviation field, Beamsville.

Montreal, Que.—The administrative commission have recommended to the city council the construction of a sewer on Cavendish Ave., from Cote St. Luc to Terrebonne Ave., at a cost of $28,000.

Penticton, B.C.—Next January the ratepayers will be asked to vote on a $35,000 by-law for a new reservoir and other extensions to the waterworks system. Clerk, B. C. Bracewell.

Peterborough, Ont.—The city engineer has recommended the following sewage disposal plant to council: the design of a two-story sedimentation plant, followed by sprinkling filters, these, in turn, to be followed by humus tanks, from

which the effluent would flow into the river. R. H. Parsons, city engineer.

Petrolea, Ont.—Tenders will be received until 6 p.m., October 15th, by the council of the township of Enniskillen for repair of the McCrae drain. A. Stonehouse and A. Elliott, commissioners.

Port Hope, Ont.—Tenders will be received by J. W. Sanders, town clerk, up to 12 o'clock noon on October 9th, 1919, for the construction of a sewer on Princess St., according to plans and specifications which are on file at the town clerk's office.

Quebec, Que.—The city medical health officer, Dr. Paquin, is advocating construction of a filtration plant to clarify and filter the domestic supply, obtained from Lake St. Charles.

Sarnia, Ont.—City council intends to construct a sewer on the east side of River St., from Chippewa to Clifford St.

Sarnia, Ont.—Tenders addressed to John A. Baird, city engineer, will be received up to noon, October 10th, 1919, for the construction of a vitrified sewer on Savoy St., from Devine to Confederation St. Plan and specifications may be seen at the office of the city engineer, city hall.

St. John, N.B.—Council has decided to construct water main and sewer on Jacques Cartier St. by day labor. Tenders rejected for sewer from Laurin and Leach; for water mains from Laurin and Leach, $11,343. Estimated cost from city engineer's tenders, sewer, $1,800; water mains, $10,000.

Wallaceburg, Ont.—Extensions to the town's waterworks plant and mains are being considered. Superintendent, Mr. McNeice.

LIGHT, HEAT AND POWER

Lakefield, Ont.—The ratepayers of Lakefield have endorsed the installation of the hydro-electric system throughout the town. Estimated cost of construction, $26,000.

TENDERS FOR ANNUAL SUPPLIES

Tenders will be received by registered post only, addressed to the Chairman, Board of Control, City Hall, Toronto, up to 12 o'clock, noon, Tuesday, October 28th, 1919, for the supply and delivery of:—

No. 1—Brass and Bronze Castings.
No. 2—Brass Work for House Services.
No. 3—Cast-Iron Pipe.
No. 4—Hydrants.
No. 5—Pipe, Fittings and Valves.
No. 6—Lead Pipe.
No. 7—Special Castings.
No. 8—Stop Valves.
No. 9—Refined Asphalt.
No. 10—Paving Blocks, Vitrified.
No. 11—Treated Wood Blocks.
No. 12—Sewer Brick.
No. 13—Iron Castings, Manholes, Gullies and Grates.
No. 14—Portland Cement.
No. 15—Mineral Dust.
No. 16—General Supplies.
No. 17—Gravel.
No. 18—Granite Setts.
No. 19—Iron and Steel.
No. 21—House Numbers.
No. 22—Oils.
No. 23—Sewer Pipe.
No. 26—Rubber Valves.
No. 27—Trap Rock.
No. 28—Sand.
No. 29—Crushed Stone.
No. 30—Rubble Stone.
No. 33—Trainmen's Uniform Suits.
No. 34—Liquid Chlorine.

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. Tenders must comply strictly with conditions of City By-law as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH (Mayor),
361 Chairman, Board of Control.

Minnedosa, Man.—The provincial power commission will undertake to provide the town of Minnedosa with a temporary power plant for the coming winter, and next year to provide a permanent plant, to have an ultimate capacity as follows: hydro-electric, 400 horse-power; steam auxiliary, 400 horse-power. R. M. Leamy, commissioner.

Ottawa, Ont.—Tenders will be received by the Ottawa Hydro-Electric Commission until 12 o'clock noon, October 10th, 1919, for one generator set. Specifications may be seen at the construction office of the Commission, 75 Laurier Ave. West. J. E. Brown, general manager.

Portage la Prairie, Man.—The Portage transmission lines, at present under construction, will be completed about December 1st. The construction of the power-house will be commenced immediately.

Wingham, Ont.—A by-law will be prepared, providing for taking of a plebiscite on the question of bringing hydro power into Wingham. The construction and installation of the proposed plant will cost $40,000.

Winnipeg, Man.—City council intends to install ornamental street lights on both sides of Donald St., from Portage Ave. to Graham Ave. Estimated cost, $3,200. City clerk, C. J. Brown.

Winnipeg, Man.—The provincial power commission have received applications for power from the following municipalities: Virden, Elkhorn, Oaklake and Oakville. R. M. Leamy, commissioner.

Yarmouth Tp., Ont.—Landowners, living between Orwell and St. Thomas and between St. Thomas and Sparta, have applied for approximaely 400 horse-power from the Hydro-Electric Power Commission. Provision was made in the construction of the St. Thomas power station to handle the additional lines necessary, and it is expected that construction of transmission lines will proceed immediately.

RAILWAYS

Calgary, Alta.—City council has agreed to two new street car line extensions. City clerk, J. M. Miller.

Edmonton, Alta.—The Utilities commission will recommend to city council the construction of extensions of the street railway along Brandon Ave., from the present terminus at Calder to a point not less than five blocks easterly. Construction to be completed this fall.

Edwardsburg Tp., Ont.—The C.P.R. is preparing plans for construction of branch line from the Ottawa-Prescott line, in Grenville county, to the section known as Crowder's Hill, in the township of Edwardsburg.

Halifax, N.S.—The C.N. Ry. will electrify the line between Halifax, N.S., and Moncton, N.B. The plans include construction of a large power-house at Maccan, Cumberland county.

Ottawa, Ont.—D. D. McKenzie will urge the Dominion government to extend the I.C. Ry. into the sections of the maritime provinces which are at present without railway communication.

Ottawa, Ont.—It is reported that the Canadian Pacific Ry. is projecting the construction of a spur line from its Ottawa-Prescott branch in Grenville county to the section known as Crowder's Hill, in the township of Edwardsburg. The spur line would be upwards of a mile in length.

Sherbrooke, Que.—Construction has commenced on the street railway extensions in the west ward of the city of Sherbrooke. J. Walsh, superintendent.

Vancouver, B.C.—Sir Donald Mann recently visited the Big Missouri mine near here, where he met in consultation Prof. Bancroft, of McGill University, and F. H. Minard, consulting engineer, of New York. A trail is being built connecting with the Premier mine-Stewart trail, and it is considered not improbable that a railroad may be built from the Big Missouri to Stewart next year.

Three views of Tarvia-filled macadam roads in County of York, Ont. Built with "Tarvia X" 1917, Toronto and York Roads Commission.

County of York (Ont.) Highways—Built and Maintained with Tarvia

THE highways shown in the three photographs are splendid examples of Tarvia roads.

All of these highways were constructed in 1917 with "Tarvia-X."

The photographs were taken more than a year later. Note the excellent condition of the roads—the smooth, firm, easy-traction surface.

Tarvia Ideal for the Roads of the Dominion

Using Tarvia for a binder makes a road waterproof and frost-proof, and for that reason Tarvia construction is particularly suited to the requirements of the roads of the Dominion which must be able to come through the severe Canadian winters without damage.

Experience has proved that Tarvia does away with the extensive spring repairs that untreated roads nearly always need after a hard winter.

Indeed, Tarvia proves to be a good investment of the taxpayer's money, not an expense, for in the long run Tarvia *pays for itself in lower maintenance cost.*

For instance, an occasional Tarvia treatment will keep these County of York highways mudless and dustless, and in fine condition indefinitely at very small cost.

We shall be glad to give you further information about these County of York roads on request. *Booklets free.*

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by any one interested.

If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention.

Tarvia

Preserves Roads—Prevents Dust

MONTREAL TORONTO WINNIPEG VANCOUVER The Barrett Company LIMITED ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Whitby, Ont.—One hundred delegates, representing municipalities along the old Toronto and Eastern Ry., have voted in favor of by-laws providing for acquisition and extensions of the Toronto and Eastern Ry. By-laws will probably be submitted in January.

Winnipeg, Man.—The Dominion government contemplates surveys for construction of a new line, approximately 75 mls. in length, extending into the mineral belt of northern Manitoba. Hon. T. C. Norris, Winnipeg..

FACTORIES AND LARGE BUILDINGS

Belleville, Ont.—Tenders will be received until October 17th by the department of public works, Ontario, for excavations for foundation and building concrete foundation walls of the new main building at the Ontario School for the Deaf. Plans, etc., at office of the bursar of the school and at the department. H. F. McNaughten, secretary.

Brandon, Man.—The Townsley Manufacturing Co. is building a new warehouse and factory on Ninth St.

Brantford, Ont.—A new $10,000 extension is being built to the Brantford Oven and Rack Co. works.

Brantford, Ont.—The board of education contemplate construction of an addition to the collegiate institute.

Brantford, Ont.—Contract for the erection of a new plant for the Robins and Myers Co. has been let to H. K. Forguseon, of Cleveland, Ohio. Only one large building is at present contemplated, 150 ft. by 360 ft.

Brantford, Ont.—The Dominion and the Ontario governments will pay 50 per cent. of cost of construction, and from 25 to 75 per cent. of salaries of instruction, in connection with the proposed new technical school for Brantford.

Calgary, Alta.—Contract has been awarded by the school board, for construction of school at Sunnyside to Fred. Jones Construction Co. Contract price, $34,493.

Chatham, Ont.—The Chamber of Commerce has passed a resolution in favor of the city council appointing a housing commission to construct homes under the provincial housing act.

Estevan, Sask.—The Dominion, Manitoba and Saskatchewan governments will establish, co-operatively, a lignite briquette manufacturing plant. Capacity of plant, 30,000 tons. J. M. Leamy, lignite board.

Galt, Ont.—The Royal Bank has purchased the old central hotel property, and will erect a new bank building next spring. W. Philip, manager.

Glace Bay, N.S.—A new schoolhouse may be built on York St. at a cost of $20,000.

Glace Bay, N.S.—The Dominion government has granted $85,000 for repairs to the harbor here.

Gladstone, Man.—School board decided to erect a new eight-roomed school building next spring at an estimated cost of $50,000.

Guelph, Ont.—Contract has been awarded by O. A. C. for construction of an apiary building to P. H. Secord & Son, Brantford. Contract price, $40,000.

Guelph, Ont.—The contract for the erection of an apiary building at the Ontario Agricultural College has been awarded to P. H. Secord and Son, of Brantford. The building will be of brick and stone, and will cost $40,000. P. H. Secord and Son have also secured the contract for the erection of an addition to the hardware foundry of the Taylor, Forbes Co. It will be 1,000 by 40 ft. and one story high, built of brick and steel, and will cost $15,500.

Ingersoll, Ont.—Directors of the Ingersoll Fair contemplate construction of a grandstand in the exhibition grounds.

Ingersoll, Ont.—Ratepayers will vote on October 17th, on the question of construction of a new Central school.

Kitchener, Ont.—A large theatre will be constructed on the north side of King St., between Foundry and Young St. Seating capacity, 1,700. Estimated cost, $150,000. Manager McCutcheon.

Lindsay, Ont.—Contract has been awarded by the Horn Bros. Woollen Mills, to John Gray Construction Co., Toronto, for construction of an addition to mill.

Lindsay, Ont.—It is expected that the school board will shortly have plans prepared for construction of additions to the collegiate institute.

London, Ont.—Plans are being prepared for construction of a new plant for London University to be erected on the Kingsmill farm. Work will probably commence in the spring. Estimated cost, $1,000,000.

London, Ont.—The Y.W.C.A. will erect a club-house and construct a swimming pool at Hunt's Flats, which has been presented to the association by the city of London.

London, Ont.—It is understood that a company is being formed to construct a ten-story hotel, containing 500 rooms, to be on the south-east corner of Dundas and Wellington St. Estimated cost, $1,000,000.

London, Ont.—Schemes for the expansion of Western University are maturing, and it is hoped that work on the construction of the new million dollar plant will be commenced within the next few months.

London, Ont.—A movement is on foot to create a million dollar endowment for a Roman Catholic college in this city which will include the removal here of L'Assomption College of Windsor and the Ursuline Academy of Chatham. Bishop Fallon has in hand about $500,000 for the extension of St. Peter's Seminary as part of the plan.

Midland, Ont.—The Curling Club will erect a new rink building this fall. Estimated cost, $14,000. Time of completion, January 1st, 1920.

Montreal, Que.—Repairs to Christ Church Cathedral, estimated to cost $40,000, are contemplated. Vicar, Rev. Dr. Symonds.

Montreal, Que.—A deputation, representing the legal profession of Montreal, recently waited on Sir Lomer Gouin, Premier of Quebec, to request his co-operation in constructing either a new wing to the present court house, or to construct an entirely separate building. Estimated approximate cost, $500,000.

Moose Jaw and Prince Albert, Sask.—Separate tenders will be received at the office of H. A. Dixon, chief engineer, Canadian National Railways, Winnipeg, until 12 o'clock noon, October 13th, 1919, for the supply of all labor and materials for the erection and completion of the following: Moose Jaw—Freight shed and offices. Prince Albert—Three-stall extension to engine-house. Plans and specifications may be obtained at the office of the district engineer, Saskatoon; building inspector, new C.N.R. station, Moose Jaw; agent's office, Prince Albert; architect's office, Winnipeg.

New Toronto, Ont.—Contract has been awarded by the Goodyear Tire & Rubber Co. for addition to factory as follows: McGregor & McIntyre, steel; Carmichael Waterproofing Co., Ltd., roofing. Estimated cost of building, $200,000.

Niagara Falls, Ont.—The collegiate board have awarded contract for technical school to the Canadian Engineering & Contracting Co., Hamilton. Contract price, $104,500. Rejected tenders from Dickie Construction Co., Hamilton, $112,000; John V. Gray Construction Co., Toronto, $133,800; R. O. Blayney, Niagara Falls, $117,700; W. Hodgins, Niagara Falls, $106,500. Additional costs for plumbing, heating and electrical work will probably increase total cost to approximately $125,000.

Niagara Falls, Ont.—The school board proposes to construct two additional rooms at the Glenview public school, $23,000; and four additional rooms at the Kitchener St. school, $40,000. W. J. Seymour, city clerk.

Oshawa, Ont.—Contract has been awarded by the board of education for construction of four-room addition on the rear of the Mary St. public school, to Davidson, Smith's Falls, $60,000. Contract for plumbing and heating not yet awarded.

Oshawa, Ont.—The Russell-Navin Construction Co., Toronto, have commenced work on construction of examining warehouse on Wellington St. Cost of building, $23,000.

Ottawa, Ont.—The directors of the Hunt and Motor Club plan extensions to the club house, which includes provisions for a new banqueting hall. W. Y. Denison, 298 Laurier Ave., secretary.

Ottawa, Ont.—The hospital board recommends to board of control, the appointment of Stevens and Lee, Toronto, as architects for the design of the new hospital. Retaining fee to be 7 per cent. of total cost. Approximate cost of hospital, $1,500,000. D. M. Finnie, chairman of board.

Peterborough, Ont.—Contract for construction of the Memorial school, recently awarded to Graham and Hayes (see *The Canadian Engineer*, issue of September 25th, page 50), has been cancelled and awarded to R. Sheehy. Contract price, building, $160,000.

Preston, Ont.—Additional improvements for Speed Park, contemplated by the parks board, are as follows; to provide a bathing pool with pure filtered running water from the Speed River; to provide a pavilion for dancing, refreshments and general shelter; to erect a large grandstand; to improve the river bank and provide boat houses; and to construct permanent walks and driveways.

Regina, Sask.—Contract has been awarded to the Poole Construction Co., by the Canadian Consolidated Rubber Co., for construction of three additional stories in steel and reinforced concrete to the present warehouse at 1118 Broad St. Contract price, $40,000.

Regina, Sask.—The contract has been awarded for the erection of a warehouse for H. G. Smith to Thos. Barnard, of this city, at a figure in the neighbourhood of $40,000. Architects, Storey and Van Egmond. Work on the new structure will commence at once.

Regina, Sask.—The following permits have been issued by the building inspector's department; factory for the Sanitary Bakers, Ltd., $45,000; factory for the Allen bakery on Garnet St., $15,000; warehouse on Broad St., for the Goodyear Tire and Rubber Co., $68,000.

Russell, Man.—Tenders for the erection and completion of a metal-clad curling and skating rink will be received by A. B. Callin, town clerk, up to 8 o'clock p.m., Monday, October 13th. Plans and specifications may be seen at the clerk's office, or at the office of the Metal Shingle and Siding Co., Dublin Ave., Winnipeg.

Selkirk, Man.—Hon. George Grierson, Provincial Minister of Public Works, awarded the contract for the construction of a new laundry building for the Hospital for the Insane to the Carter, Halls, Aldinger Co., Winnipeg, for $47,229, and for the heating and plumbing apparatus and the installation of the machinery to the James Ballantyne Co., Ltd., of Winnipeg, for $18,275.

St. Boniface, Man.—A building permit has been granted to the Ceiling and Roofing Co. to build a 100 by 125 ft. addition to their plant for the manufacture of sheet metal products. Estimated cost, $15,000. The contractors are Carter, Halls, Aldinger Co., Winnipeg.

St. Boniface, Man.—The Western Wheel and Foundries Co., Winnipeg, a subsidiary of the Dominion Wheel and Foundries, Ltd., will establish large works here. The capacity of the plant will be 100,000 car wheels a year. The first unit will be completed so that operations may be commenced early in 1920. J. A. Kilpatrick is president and general manager.

St. Stephen, N.B.—Extensions will be constructed to the shoe factory, owned by the municipality, and operated by the Clark Bros. Shoe Co.

St. Thomas, Ont.—Board of education contemplates construction of a six-room school in the Wilson Ave. district. Estimated cost, $75,000. Tenders will soon be called. Architect, Darrach.

St. Thomas, Ont.—Molsons Bank have received permit for construction of bank building at the corner of Talbot and Flora St. Estimated cost, $37,000.

Thorold, Ont.—Tenders will be received until 5 p.m., October 15th, by the Great War Veterans' Association, for construction of club building. Plans, etc., A. B. Begg, Front St., Thorold, or architect, T. D. Mesler, 110 St. Paul St., St. Catharines, Ont.

Toronto, Ont.—The Merchants Bank will erect a four-story bank building at 12 King St., West. Estimated cost, $180,000.

Toronto, Ont.—Wm. Davies has intimated his intention of donating $30,000 for the erection of a women's residence in connection with McMaster University, University of Toronto.

Vancouver, B.C. — Ratepayers defeated proposals to spend $511,000 on erection of new schools, including a technical school building and equipment.

Vancouver, B.C.—The Standard Motors, Ltd., have taken out a permit for the erection of a new garage and showrooms at the corner of Eighth Ave. and Kingsway, to cost $22,000. The building will be of concrete.

Vancouver, B.C.—The Britannia Wire Rope Co., Ltd., with which is associated the local firm of Gibson's Ltd., has been registered with an authorized capital of $100,000. A site has been secured on Granville Island for the erection of a factory.

Windsor, Ont.—Plans are being prepared for construction of a large modern moving picture theatre on Wyandotte St. F. S. Ferguson, Standard Iron Foundry, Walkerville, director.

Windsor, Ont.—The C.P. Ry. will construct a large new freight shed, which will have modern freight handling equipment. A. Williams, superintendent.

Winnipeg, Man.—The Riverview Lawn Bowling Club plan to erect a curling rink building late this fall.

Winnipeg, Man.—A. J. Holling, steel manufacturer, Sheffield, England, while in Winnipeg recently, announced his intention of transplanting his works from Sheffield to Winnipeg.

Winnipeg, Man.—Weidman Brothers, 244 Jarvis Ave., have received a permit to alter their premises from a one-story to a three-story structure. A. J. Burnett and Sons have the contract, and M. Blankstein is the architect.

Winnipeg, Man.—Plans for the construction of the nurses' home in connection with the Winnipeg General Hospital are being revised by the engineer for the hospitals' commission. It is expected that construction will begin immediately. Estimated cost, $300,000.

Winnipeg, Man.—Building permits for September totalled $624,050 as against $144,850 for the corresponding month of last year. Official figures from the building inspector's department also show that to this date last year the aggregate was $1,892,750, as compared with $2,115,900 to date this year.

York Tp., Ont.—Tenders will be received until 12 o'clock noon, October 15th, by the York Tp. Housing Commission for construction of dwellings on the following streets; Eaton Ave., Johnstone Ave., Hillcrest Bvd., Westlake Ave., Dawlish Ave., Raymond Ave., and Meagher Ave. J. A. Martin, secretary, 40 Jarvis St., Toronto.

MISCELLANEOUS

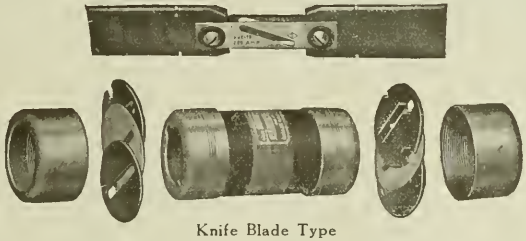
Esquimalt, B.C.—The provincial government will call for tenders about the middle of this month for the construction of the Esquimalt drydock.

Glace Bay, N.S.—The department of public works, Ottawa, will improve the harbor as soon as the Dominion Coal Co. transfers ownership to the department. Channels will be dredged. Appropriation, $50,000.

(Concluded on page 54)

Northern Electric
SHAWMUT
Renewable Fuses

Simple — Reliable — Economical



Knife Blade Type

Ferrule Type

FUSES are for protection—to give protection they must be accurate—well constructed and reliable. Northern Electric Shawmut Renewable Fuses represent years of engineering study which has produced fuses that give maximum protection.

Construction—thick horn fibre tubes reinforced at the ends to prevent damage by blowing—caps of heavy metal accurately machined and all threads are metal to metal.

Ease of Renewal—to renew the ferrule type no tools are needed; for the knife blade type, only a screw driver.

Ask our nearest house to demonstrate the Northern Electric Shawmut Renewable Fuses, or to send you literature and reduce your fuse bills while retaining maximum protection.

FAIR WAGE SCHEDULES

Public notice is hereby given that, under the provisions of Section 10, Chapter 1, of the Statute of Manitoba, 1916 (being the Fair Wage Act, 1916), the Minister of Public Works has approved of the rates per hour and working hours set forth in the following schedule, with the minimum rate per hour payable to any employee engaged in the respective trades, and the maximum number of hours during which any employee engaged in the respective trades shall be required to work; and that the said schedule shall apply and be effective for employees engaged on public works on or at the building; and that the said schedule shall be effective from the first day of September, A.D. 1919, to the thirtieth day of April, 1920, or until such time as another order may be made by the said Minister of Public Works.

Fair Wage Schedule for Winnipeg

The following schedule shall apply to the City of Winnipeg and a radius of thirty miles therefrom, from the first day of September, 1919, to the thirtieth day of April, 1920:—

	Rate per Hour.	Hours per Week.
1. Common Laborers	.45	54
2. Builders' Laborers (being those directly engaged assisting tradesmen, not otherwise classified)	.55	50
3. Teamsters (employed directly from or on the buildings)	.50	60
4. Bricklayers	$1.00	44
5. Stonemasons	$1.00	44
6. Marble Setters	.95	44
7. Mosaic and Tile Setters	.77½	44
8. Terrazo Workers—		
(a) Layers	.70	44
(b) Helpers	.55	54
9. Stone Cutters—		
(a) Carvers	.97½	44
(b) Journeymen	.85	44
(c) Planermen and Lathemen	.75	44
10. Plasterers	.90	44
11. Wood, Wire and Metal Lathers	.75	44
(a) Where Metal Lath only is used	.80	44
12. Plumbers	.80	44
13. Steamfitters	.80	44
14. Operating Engineers on Construction—		
(a) Engineers in charge of machines of three or more drums	$1.00	50
(b) Engineers in charge of double-drum machines	.90	50
(c) Engineers in charge of single-drum machines	.80	50
(d) Firemen	.55	50
15. Sheet Metal Workers	.73½	44
16. Painters, Decorators, Paperhangers and Glaziers	.70	44
17. Blacksmiths	.70	44
18. Electrical Workers (Journeymen Inside Wiremen)	.75	44
19. Bridge and Structural Steel and Ironworkers	$1.00	44
20. Asbestos Workers—		
(a) Journeymen	.80	44
(b) First Class Improvers	.70	44
(c) Second Class Improvers	.60	44
21. Asphalters—		
(a) Finishers	.60	44
(b) Men engaged preparing, mixing and heating materials	.45	54
22. Carpenters	.75	44

Fair Wage Schedule—Province of Manitoba (Exclusive of Winnipeg)

	Rate per Hour.	Hours per Week.
1. Common Laborers	.40	54
2. Builders' Laborers (being those directly engaged assisting tradesmen, not otherwise specified)	.50	50
3. Teamsters (employed directly from and on the building)	.45	60
4. Bricklayers	$1.00	44
5. Stonemasons	$1.00	44
6. Marble Setters	.95	44
7. Mosaic and Tile Setters	.77½	44
8. Terrazo Workers—		
(a) Layers	.70	44
(b) Helpers	.55	54
9. Stone Cutters—		
(a) Carvers	.97½	44
(b) Journeymen	.85	44
(c) Planermen and Lathemen	.75	44
10. Plasterers	.90	44
11. Wood, Wire and Metal Lathers	.75	44
(a) Where Metal Lath only is used	.80	44
12. Plumbers	.80	44
13. Steamfitters	.80	44
14. Operating Engineers on Constructions—		
(a) Engineers in charge of machines with three or more drums	$1.00	50
(b) Engineers in charge of double-drum machines	.90	50
(c) Engineers in charge of single-drum machines	.80	50
(d) Firemen	.55	50
15. Sheet Metal Workers	.73½	44
16. Painters, Decorators, Paperhangers and Glaziers	.70	44
17. Blacksmiths	.70	44
18. Electrical Workers (Journeymen Inside Wiremen)	.75	44
19. Bridge and Structural Steel and Ironworkers	$1.00	44
20. Asbestos Workers—		
(a) Journeymen	.80	44
(b) First Class Improvers	.70	44
(c) Second Class Improvers	.60	44
21. Asphalters—		
(a) Finishers	.60	44
(b) Men engaged preparing, mixing and heating materials	.45	54
22. Carpenters	.75	44

Fair Wage Schedule—New Parliament Buildings, Winnipeg

The following schedule shall apply and be retroactive on the work of the new Parliament Buildings, Winnipeg, from July 1st, 1919, to August 31st, 1919:—

Item No. 1—Common Laborers ..... .40c. per hour.
" " 2—Builders' Laborers ..... .50c. " "
" " 4—Bricklayers ..... .95c. " "
" " 5—Stonemasons ..... .95c. " "
" " 6—Marble Setters ..... .90c. " "
" " 7—Mosaic and Tile Setters ..... .75c. " "
" " 10—Plasterers ..... .85c. " "
" " 12—Plumbers ..... .75c. " "
" " 13—Steamfitters ..... .75c. " "
" " 18—Electrical Workers ..... .70c. " "
" " 22—Carpenters ..... .75c. " "

The following schedule shall be effective as retroactive from the first day of August, 1919, to the thirty-first day of the same month:—

Item No. 9—Stone Cutters—
(a) Carvers ..... .97½c. per hour.
(b) Journeymen ..... .85c. " "
(c) Planermen and Lathemen .75c. " "

By Order. (Sgd.) GEORGE A. GRIERSON,
Minister of Public Works.

Dated at the Office of the Provincial Secretary this twenty-fifth day of September, A.D. 1919.

360 (Sgd.) J. W. ARMSTRONG, Provincial Secretary.

Good Books for Municipal Engineers

Sewage Disposal *Second Edition Rewritten*

By the late LEONARD P. KINNICUTT, C. E. A. WINSLOW, and R. WINTHROP PRATT.

A completely rewritten book, treating in an authorative and up-to-date manner the recent viewpoints in connection with this most important subject. Workers engaged in reconstruction will find it a constant and reliable assistant.

xvii+547 pages. 6 by 9. 141 figures. Cloth, $4.00 net.

Water-Supply Engineering *Third Edition Rewritten*

The Designing and Constructing of Water-Supply Systems. By A. PRESCOTT FOLWELL, Editor of Municipal Journal.

In this edition the matter treating of water purification and the quality of water has been entirely rewritten, that describing pumping machinery is practically new throughout, while the remainder of the original text has been materially revised and rearranged so as to present the subject matter in a more logical order.

xv+484 pages. 6 by 9. 125 figures. Cloth, $3.50 net.

Sewerage *Eighth Edition Rewritten*

The Designing, Constructing and Maintaining of Sewerage Systems and Sewage Treatment Plants. By A. PRESCOTT FOLWELL.

More space than heretofore is devoted to the calculating of the sizes of sewers, especially storm sewers, and to pumping sewage. Part II, treating Construction, and Part III, on Maintenance, on the other hand, have been condensed to one chapter each. The book as a whole covers thoroughly the fundamental principles and approved practices of both sewerage and sewage treatment.

xii+473 pages. 6 by 9. 80 figures, 12 plates. Cloth, $3.00 net.

Engineers engaged in construction work have found

Waterproofing Engineering

By JOSEPH ROSS, B.S., C.E.

An authoritative work explaining in a clear and understandable manner past and present methods and materials of waterproofing. One reviewer says of it: "This volume fills the long-felt need of a complete discussion of methods and types of waterproofing. A valuable publication for the municipal engineer."

x+442 pages. 6 by 9. 140 figures. Cloth, $5.00 net.

The Planning of the Modern City

By NELSON P. LEWIS, Chief Engineer, Board of Estimate and Apportionment, New York City.

This book is devoted almost entirely to the engineering aspects of its subject, and the municipal engineer will find in it much valuable information that will bring to him a keener realization of his part in, and responsibility for, the constructive work of city planning and building.

xv+423 pages. 6 by 9. 62 figures, 87 full-page plates. Cloth, $4.00 net.

MISCELLANEOUS

(Continued from page 50)

London, Ont.—By-law being prepared by city council to be voted on in January provides $100,000 for construction next summer of one-half of a partitioned reservoir on Springbank Hill. Total capacity of reservoir, 20,000,000 gals. Total cost of construction, $200,000.

Montreal, Que.—The Dominion Bridge Co., Ltd., has been awarded contract by the Laurentide Paper Co. for construction of an entire set of paper-making machines. Work will be undertaken at the Lachine plants.

Port Colborne, Ont.—The Athletic Club will construct an artificial ice plant in connection with the new rink building.

Port Maitland, Ont.—Tenders will be received until 12 o'clock noon, October 20th, by the department of railways and canals, Ottawa, for reconstruction of the east pier at Port Maitland, Ont. Plans, etc., at office of superintending engineer, St. Catharines, Ont., and at the department. J. W. Pugsley, secretary.

Prescott, Ont.—It is said that the G.T. Ry. will erect a large coal storage terminal at Prescott.

St. Catharines, Ont.—The department of railways and canals, Ottawa, have issued orders to stop work and dismantle plant on section No. 2, Welland ship canal. Contractors, Baldry, Yerburgh & Hutchinson.

Ste. Famille, Que.—Tenders will be received until 12 o'clock noon, October 16th, for repairs and reconstruction to wharf. Plans, etc., offices of district engineers, post office building, Quebec, Que.; Shaughnessy building, Montreal, Que.; and at post office, Ste. Famille, Island of Orleans, Que. R. C. Desrochers, secretary.

Vancouver, B.C.—The board of trade have requested the Dominion government to proceed with the work of the harbor improvements, for which $5,000,000 has been voted. H. H. Stevens, M.P.

Winnipeg, Man.—Judgment given by Justice Curran orders T. H. Kelly, contractor, to repay to the government of Manitoba $1,207,351.65, with interest at 5 per cent. since July 1st, 1914. The board of appraisal decided that this amount had been overpaid during construction of the Manitoba parliament buildings.

Tenders Called For

UNITY, SASK.

Sealed Tenders registered and endorsed on the envelope, Tenders for (tender bid on) and addressed to J. M. Jensen, Secretary-Treasurer of the Town of Unity, Sask., will be received up to 6 p.m., October 15th, 1919, for the supply, delivery and erection of the following machinery and materials and for the performance of certain works:—

Tender A. For the supply, delivery and erection of one internal combustion engine.
Tender B. For the supply, delivery and erection of one generator excitor, switch-board, transformers, meters, etc.
Tender C. For the supply and delivery of one oil storage chamber.
Tender D. For the supply and delivery of pole, wire and line material.
Tender E. For the erection of electric pole line.
Tender F. For the erection of Power station and cooling tank.

Marked cheque for five per cent. (5%) of the amount of the bid must accompany each tender.

Complete sets of plans and specifications may be seen at the office of the Consulting Engineers, Saskatoon, at the Secretary-Treasurer's office, Unity, Sask. Specifications on tenders A., B., C. and D. may be seen at the office of *The Canadian Engineer*, Winnipeg and Toronto, and the Contract Record office, Montreal.

Heavy Steel Highway Bridging at the Front

Four General Types Used by the British Army in France for Spans Greater Than 30 Ft.—Inglis, 60-Ft., 85-Ft. and Hopkins Types—Loads, Foundations, Details of Design and Novel Methods of Launching

By A. C. OXLEY, M.C., D.C.M.

Formerly Lieutenant, 10th Canadian Engineer Battalion

IN the following brief record of the methods and types of spans used for highway bridges by the British Army during the recent great war, no attempt is made either to discuss standard-gauge railway spans or to take up in detail the very first bridges erected after an advance—namely, the infantry barrel-pier footbridges and the pontoon bridges used by the first-line transport.

The subject to be discussed may be called "Heavy Highway Bridging" for loads starting with the standard three-ton-capacity lorry and reaching their limit in the modern tank. The loads and methods are those of the British "G.H.Q. Heavy Bridging School," which, during the course of the war, in the winter months only, gave a series of courses of from two to three weeks' duration, to officers and others of the Royal Engineers and colonial engineering units who had already received all the usual technical training in light bridging and who had also received a fair share of "battle training."

The bridging school, under Lt.-Col. Robinson, with its supply base at Havre, was organized on the assumption that the Germans would fight a strong rearguard action from the Ypres-Amiens line clear back to the Rhine, destroying all bridges and communications on the way. Records and plans were obtained and kept of all bridges constructed before the war in Belgium and North-east France, and enough material was stocked at Havre to replace the bridges most essential for the re-establishment of communications. Actually, the destructiveness of the Germans ceased near Mons and the destroyed gap was only about 60 miles in width.

Loads

Following is the classification of bridges by loads from the AA class, which carried tanks, to the H class, which carried infantry in single file:—

Class AA—Crowded 30-ton tanks.
" A—17-ton axle loads at 15-ft. centres, or whippet tanks.
" B—Caterpillars at 11 tons.
" C—Foden 5-ton-capacity steam lorries.
" D—3-ton lorries, 60-pdr. guns.

Class E—Field guns (3-in. and 4.5-in. howitzers), and all horse-drawn vehicles.
" F—Infantry in file, pack mules.
" G—Cavalry, dismounted, single file.
" H—Single file infantry.

[NOTE.—Ordinary pontoons were of Class E only. All guns would go on Class B, except a 6-in. British long (naval). The Inglis bridge was rarely used for over a Class C. load.]

Tanks, of course, were in a class by themselves, but a "heavy" bridge was usually of at least B class and thus could carry all other highway traffic loads such as steam rollers and dismantled heavy howitzers, the tractors of which imposed an axle load up to about 13 tons.

The tank was regarded as having its load of 30 tons distributed over a length of 4 ft. and its "sponsons" for its 6-pounders, or machine guns, projected to a total width of 12 ft. 9 ins., which was much in excess of the standard clearance width of 11 ft. 6 ins. It was, therefore, frequently necessary for a tank to draw in its sponsons in order to cross a bridge, and so be delayed for several hours. The standard height clearance was 12 ft. 6 ins., which was close enough to compel passengers to descend from the second story of the London busses so often seen at the front.

Foundations

All spans were of steel, with close fitting bolt connections. These bolts were 1¼ ins. or $1\frac{5}{16}$-in. diameter of shaft, with a threaded end of 1⅛ ins. or $1\frac{3}{16}$ ins. respectively, which both ensured tightness and also minimized danger of stripping bolt threads.

The foundations normally were simply timber mudsills and one to three 12 by 12-in. timber bridge seats for abutments on dry firm soil. For piers it was often necessary to construct pile trestles. The loading on mudsills was kept down to about ¾ ton per sq. ft., and care was taken to keep the toe of the mudsill at crest within a 1 to 1 slope to water level.

The bridge rollers on the larger spans were about 3 by 4 ft. on their base, giving a good bearing area on bridge seats, and the latter were figured as beams with trusses causing two downward concentrated loads, and mudsills causing a distributed upward reaction. Each 12 by 12-in. bridge seat was continuous under both trusses in order to avoid unequal settlement.

In certain cases such as when a canal with a tow path was being bridged, cribs were built of steel cubes, with 4-ft. face, of light angles. These cribs were not allowed to exceed 12 ft. in height and could not be used to advantage in midstream.

Piling was often done with man or horse power lifting a 1,500-lb. monkey on the formula:—

Bearing strength of pile = [(Fall of M, in ft.)$^{1/3}$ × (Wt. of M, in cwt.) × ½] ÷ [1 + (set of last blow, in ins.)]

It was found that working outwards from the shore was very slow, and it was often possible to use the bridging pontoons as rafts and to drive from them. For a pile-bent trestle it was then possible to construct the whole bridge of pontoons and to drive a bent between each pair of close-lashed pontoons.

Four Types of Bridges

Four general types of bridges were used for spans of over 30 ft. (Below this size merely enough rolled steel

joists—or R.S.J.'s were used to make up the necessary span and strength.) Of these four general types, two—the Hopkins and Inglis—are through bridges, and the other two are known as the 60-ft. and 85-ft. spans. The two latter were half deck if used in one position, or deck type if inverted. All these bridges could be varied in length, below the maximum for which they were designed, simply by omitting sections. No field riveting was done, close fitting 1¼-in. diameter black bolts being normally used, and large pins in the Inglis.

Inglis Bridge

The Inglis was originally designed with a triangular cross-section and only a single top chord, but that proved inefficient, and the later Inglis type was rectangular in cross-section. In the Inglis bridge (See Drawing No. 3), the cross-beams, both ledgers and transoms, were R.S.J. sections, with four sockets in the vertical plane at each of their ends. These sockets were pierced by heavy cross pins. The members of the trusses were heavy steel 5-in. pipes, with solid projecting ends pierced by cross holes. These truss members were slipped into the sockets on the transoms and ledgers, and the cross pins inserted. The holes, however, were slotted, so there was way to take up, and a screw sleeve on the bars was turned to prevent movement.

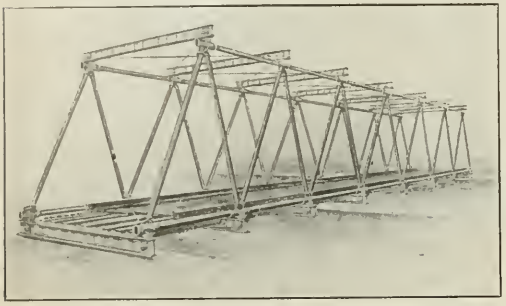
The Inglis bridge was designed in identical 12-ft. panels and made a series of equilateral triangles of the Warren type. Its great advantages were (1) speed of its erection, and (2) portability. It was often used for a week or two until a heavier bridge was erected alongside, when it was dismantled and shipped by lorry further forward.

The well-known picture, "Canadians Bridging Canal du Nord, Arras-Cambrai Road, September 28th, 1918," shows an Inglis bridge in use on the centre line of the highway. Later, two Hopkins bridges were erected on a diversion site close alongside. This Inglis bridge was good only for a Class C load of 8 tons per axle at a span of 120 ft., but it was good for a Class A load of 17 tons per axle at 72 ft. The span was about 108 ft., but the original civilian girder bridge had been dropped bodily into the shallow water directly beneath, and on the visible few inches of its top chord, a crib had been erected to support the Inglis bridge, and therefore, with a maximum span of, say, 60 ft., it could have been used for any British gun, but not for tanks.

The history of its erection is briefly this: The canal was crossed at 5 a.m., September 27th, on a dry portion about three miles south of the highway. The attacking Canadians then passed north and consolidated on the far side at approximately 8 a.m. Barrel-pier and pontoon bridges were rapidly thrown over, and by noon our field artillery were fully two miles in advance of the canal. The erection of the Inglis was commenced about noon. In addition to its true nine spans, this length required a counterweight of six more spans, in addition to a "trolley" span (in the centre) which acted as a carriage for the progression of the whole in launching. The 16 spans were not completed until dark, and as it was unwise to use lights owing to hostile aircraft, the launching was postponed until dawn. The bridge was in commission about 11 a.m., September 28th, and was used for several weeks.

The method of launching the Inglis was slightly different from that of launching the other types. All spans over 30 ft. were built on shore and launched without falsework in the river, but this type had a two-wheeled trolley, secured by jacks, just back of its rear "bridge seat." Back

of this again were about two-thirds as many panels as in the span itself. The last panel was counterweighted with some of the decking and a small live load of men, the forward end of the bridge being in skeleton only. The trolley was then manhandled slowly forward, with the forward bridge seat slightly raised, and on reaching its final position the structure was lowered. The trolley and counterweight spans were rapidly dismantled, and the stringers, solid planking and hand-railing put in place. The total labor allowance for a 120-ft. span was about 2,000 man-hours.



Typical Inglis Bridge

The other long span types were also erected without falsework and usually without a counterbalancing arm, and as the system of tackle was identical in principle in all spans over 30 ft. to a maximum of 180 ft., it will later be discussed in detail.

The 60-Ft. Span

The 60-ft. type was originally of Class A strength, but by using $1\frac{5}{16}$-in. diameter black bolts at the panel points in place of $1\frac{3}{16}$-in. diameter bolts, it was subsequently in Class AA category and could carry single tanks. Its girders were Warren trusses, the complete span being shipped in five pieces per truss—namely, 2A, 2B and 1C (see Drawing No. 3), all joints being staggered, only a single 7-in. channel and 8 by $\frac{5}{8}$-in. plate being needed at each splice. Each main member was composed of two 8-in. channels.

By the omission at will of any of the B or C pieces, the overall length of 64 ft. could be reduced to 55 ft. 4 ins., 51 ft. 0 ins., 42 ft. 4 ins., 38 ft. 0 ins. or 29 ft. 4 ins. as required.

The cross-beams, consisting of 12-in. I's at 40 lbs., were spaced in pairs between (but close to) the panel points, and had their depth at ends reduced to 7½ ins. to avoid fouling diagonals. They were bolted by their angles through the vertical centre line of trusses, and wind-bracing flats were bolted to their lower flanges. Five of them extended far enough beyond trusses to allow lateral vertical braces against upsetting of trusses.

The 4-in. decking was laid longitudinally and flared out for 4 ft. at 30 degs. at end of trusses, in the usual way, to join a graded earth roadway.

The 85-Ft. Span

The 85-ft. standard span was of similar type, but had a total depth of 8 ft. 6 ins. The main chords were of two 5 by 4 by ¾-in. angles, stiffened with a vertical web plate. This type was often used near Etaples in crossing the tidal river. Two spans were usually sufficient. Two bridges were used for highway traffic, but a third one was erected for the eventual use of the narrow gauge (60-cm. or 24-in. gauge), upon which the B.E.F. would have had to rely had they lost St. Pol in the great "Battle of France," which started March 21st, 1918. Actually, rails were not laid nor the approaches graded.

The chords of this type had greater lateral stiffness than those of the 60-ft. type, and it was quite common to launch them singly in cantilever; that is, the two trusses were erected on shore and bolted end to end. Truss 1 was then pushed and rolled until its far end reached a pier in mid-stream. The erection bolts were then removed and four special cradle rollers attached to the lower flange of Truss 1. Truss 2 was then slid along this "track." This method was particularly useful in multi-span bridges, as the tackle system of launching was only at its best in one-span bridges, where the height of its mast was of most use.

Hopkins Bridge

The Hopkins 120-ft. span was the largest, longest and had the highest load-bearing capacity of any of these G.H.Q. highway bridges. The method of its erection is shown by Drawings Nos. 1 and 2.

The erection on shore was carried out with no equipment beyond the necessary wrenches and 2-in. hemp rope, with suitable block and tackle. After laying out with camber, as shown, the party was divided into four, one for each end of each truss. All diagonals were hoisted by inserting first only one bolt per gusset plate and swinging in a vertical plane. The angles used as gallows with which to hoist the 15-in. channels of the top chord were later used as hand-rail posts. Used as originally designed they gave insufficient clearance for hoisting and were actually used with an extra plate to give height, the plates being those later used for fastening the floor cross-beams to the diaphragms.

The largest span of this type ever erected in the field was at Havrincourt, after the Canal-du-Nord operations of September 27th to October 10th, 1918. The clear span was 180 ft. and to avoid excessive strains and also excessive length of tackle, the span was partly counterbalanced by erecting 60 ft. of false or cantilever panels. The bridge then was still in equilibrium, without tackle, when overhanging about 120 ft., with the help of some decking as counterweight.

It will be observed that when the bridge was being rolled forward all stresses were reversed and the upward thrust of the rollers tended to distort the 15-in. channels of the lower chord. This was taken up by using an 18-in. 75-lb. R.S.J. floor stringer as a stiffener. In the normal case of a 120-ft. span on eight panels, only the two centre panels were thus stiffened, but in this extreme (Havrincourt) case, panels 4 to 12 were all stiffened, and the beams removed after crossing the roller to avoid overloading of the overhang.

Bridges of this type were launched in skeleton. The trusses were complete, and also the wind-bracing in the upper horizontal plane, but in place of the floor cross-beams and stringers, we had only a few pieces of decking wedged in place, with the diagonal tension taken up by means of wire ropes and turn-buckles. In the Havrincourt bridge, tarpaulins were slung below the flooring gang to save men and tools.

The bridge was launched from and supported by special rollers with a diameter of 12 ins. and a length of about 3 ft. 6 ins., as the two 15-in. channels of the lower chord were separated, and double latticed internally with 2½ by 2 by ¼-in. angles. Later a rocker was bolted under one end.

A footpath about 3 ft. wide was built on the outside of each truss, the angle-irons of its floor being spaced at 3 ft. centres, and only each alternate floor angle had an upright angle as support for the 1¼-in. diameter gas-pipe hand-rail. (See Drawing No. 2.)

A railing was also fastened inside of trusses (to guide road traffic) at an elevation of about 3 ft. The 5-in. decking was laid crosswise on the lower flange of 15-in. channels, and on two 18-in. 75-lb. I-beams spaced 6 ft. 6 ins. apart. These R.S.J.'s were set with tops of stringers about 2 ins. above tops of cross-beams, thus allowing small beveled plates to be riveted on the uncut lower flanges of the stringers and simplifying erection.

The floor was erected by means of a light steel trolley which ran on upper flanges of inner 15-in. channels. To facilitate erection the stringers were made only 14 ft. $11\frac{1}{16}$ ins. out to out on a panel length of 15 ft., and two ¼-in. fillers were later inserted. The cross-beams at side were

supported by both a long and a shorter plate, putting four of six bolts in bearing on web of 18-in. I and two in single shear. (See Drawing No. 1.)

The only other long span types of bridge were the 120-ft. Hopkins with an 18-ft. roadway, and a 75-ft. Hopkins. In the former, all chord and diagonal material was identical with the standard 120-ft. type, but the overhead horizontal wind-bracing was revised to suit, and two long plates at each end were used to fasten the 3-ft. cross girders. The 18-in. I's for stringers were practically unchanged in design but were increased to five in number.

The other type, the 75-ft. Hopkins, at the time of the armistice had never been erected. Its floor was to be identical with the 120-ft., but its top and bottom chords were to be only two 9-in. 19½-lb. channels, and its diagonals the same. It was designed to carry Class AA loads or tanks at 75 ft., single tanks at 105 ft., and all Class A loads of 17 tons at 120 ft.

The 60-ft. type was launched with tackle similar to that used for the 120-ft. type, but there was only one set to each bridge instead of one to each truss. The single derrick was braced sideways and allowed to lean slightly towards the bridge. Care had to be taken in every case when launching to adjust all tackle correctly, as it was only by fastening the tackle to the bottom of the forward end and the top of the rear end that the rotating couple of the downward thrust of the bridge and the upward thrust of the roller were counterbalanced by an equal and opposite couple.

The normal time for launching alone was about 40 minutes, and the labor cost of the entire erection of a 120-ft. Hopkins was 4,000 man-hours. On military work time is of more value than men, but about 200 men were the most that could be employed, so about three days was the minimum time of erection.

The Inglis was sometimes erected in one day on the true site, the Hopkins near it in a week on a diversion site, and the permanent civilian bridge a year or more later on the true site.

The military bridging practically ceased with the armistice. In both France and Belgium there were so many workless mechanics and laborers that the civilian authorities were encouraged to do as much as possible, and in the ensuing six months a great many of the permanent railway and highway bridges were replaced.

Fortieth Annual Convention of the American Water Works Association to be Held June 21-26, 1920, in Montreal

AT a recent meeting of the convention committee of the American Water Works Association, it was decided that the dates of the next annual convention should be June 21-26, 1920. It was decided at the last convention to hold the next assembly in Montreal, but the dates were left to the convention committee. The dates selected by this committee have to be confirmed by the executive committee of the association, but this no doubt will be largely a matter of form, as the convention committee is a sub-committee of the executive committee.

The five members of the convention committee met in Montreal last week and made final arrangements with the manager of the Windsor Hotel. Windsor Hall, adjoining the hotel, will be used for the exhibition. Access to Windsor Hall can be obtained from the hotel or directly from the street. Delegates entering Windsor Hall from the hotel will pass the rooms used as convention offices, and in order to reach the room where the papers will be read, the delegates will have to go through the exhibition hall. The convention hall will not immediately adjoin the exhibition hall, so the reading of papers will not be interfered with by the noise incidental to the exhibition.

The members of the convention committee declared that they were delighted with the arrangements that had been made, and that at no time in the history of the association have facilities been so absolutely ideal. The committee expect a big attendance of water works superintendents, contractors, consulting engineers and manufacturers from all parts of the United States and Canada. The conventions are attended every year by nearly a thousand members and guests, and it is thought that next year's convention at Montreal may prove to be a record-breaker, as a number of very interesting trips are being planned for the entertainment side of the program, and special effort will be made to have interesting papers, including a number of papers on Canadian work.

The convention committee have appointed a local committee on arrangements, consisting of a number of Montreal and Toronto members of the association, with H. G. Hunter, of Montreal, as chairman.

Association of C. B. & C. I.'s Proposed Constitution

AS a result of several months' thought and study, and after a large number of conferences with many members of the association from coast to coast, J. P. Anglin, president of the Association of Canadian Building and Construction Industries, has perfected a draft of proposed constitution and by-laws for the association. Last December the national council appointed Mr. Anglin as a committee of one to carry out this work. The constitution as prepared by Mr. Anglin has been submitted to the various members of the council, and while it has not yet been officially adopted, as no letter ballot has been sent out, a great many of the members of the council have expressed their approval, and it is thought that the constitution will be adopted with few, if any changes.

The constitution as prepared by Mr. Anglin consists of sixteen articles, covering respectively name, purpose, membership, annual fees, meetings, government and election, officers, duties of officers, executive committee, committees, order of business, expulsion and discipline, audit, seal, arbitration, and amendments.

The objects of the association are stated to be: (a) To promote better relations between the members on the one hand; and owners, architects and engineers on the other; (b) To establish and maintain standard methods of practice between members within the industry; (c) To acquire, preserve and disseminate valuable information concerning the industry; (d) To extend construction and improve conditions in the combined industry; (e) To co-ordinate the units of the industry in its producing, manufacturing, distribution, professional and constructive activities, thereby increasing its efficiency and extending its usefulness, to the end that the industry shall be established.

The membership is divided, as planned at the conference in Ottawa last November, into three sections: (a) General contractors and contracting engineers; (b) trade and sub-contractors; and (c) supply firms, manufacturers and producers of building materials and plant. Each section may be further sub-divided.

Two classes of membership are provided for: Direct,

or individual membership; and indirect, or collective membership. The latter comprises the membership of existing local builders' associations, contractors' sections of local boards of trade, etc. Such bodies are to pay an annual per capita fee of $5, minimum payment from any association to be $50. These bodies to be allowed one representative at each annual or special convention of the association for each $50 paid in fees.

The dues for individuals are to be $50 per annum for firms doing less than $500,000 business annually, with additional tax of $50 per annum for each additional $500,000 of annual business. The fiscal year commences October 1st, 1919, and all fees for the current year are to be considered as having been due upon that date. Members can resign at any time if their current dues have been paid.

The affairs of the association are to be managed by a national council, consisting of 45 members to be elected at the next convention of the association, which is to be held at Chateau Laurier, Ottawa, January 27th to 30th, 1920. Fifteen of these (according to the highest votes obtained) are to serve for a term of 3 years, 15 for 2 years, and 15 for 1 year, and thereafter 15 will be elected annually to serve a term of 3 years.

For the purpose of ensuring an equitable representation in the council, 5 councillors are to be elected from each of 9 electoral districts. These districts are as follows: District No. 1 (headquarters district)—Province of Ontario outside of District No. 2; District No. 2—City of Toronto and adjoining territory within a radius of 25 miles; District No. 3—Province of Quebec outside of District No. 4; District No. 4—Montreal and adjoining territory with a radius of 25 miles; District No. 5—Maritime Provinces; District No. 6—Manitoba; District No. 7—Saskatchewan; District No. 8—Alberta; and District No. 9—British Columbia.

In additional to the 45 members mentioned above, the chairman and secretary of each of the three main sections of the association are to be members of the national council. The president, two vice-presidents, honorary secretary and honorary treasurer are to be elected by the national council from among their number. There is to be an executive committee consisting of the officers of the association and the chairman of each of the three main sections. The national council is to direct the affairs of the association between annual conventions and the executive committee is to direct the affairs between the meetings of the national council.

RECENT PUBLICATIONS

Cole Pitometer System.—Reprint of paper read at the last annual convention of the American Water Works Association by Geo. C. Andrews, water commissioner of Buffalo, N.Y., on "Reduction of Water Consumption by Means of Pitometer Survey and House Inspection."

The Zone Plan.—Cloth bound book, 82 pages and cover, 6¾ by 10¼ ins.; published by City Plan Commission of St. Louis, Mo.; contains a number of illustrations and numerous folded maps printed in several colors. Harland Bartholomew is engineer of the commission.

Fair Average Prices in Cost of Reproduction and the Trend of Prices After the War.—By Morris Knowles, consulting engineer, Pittsburgh, Pa., and Windsor, Ont. Reprint of paper prepared for the New Jersey Utilities Association; 15 pages and cover; 6 by 9 ins.; illustrated.

Summary Report, 1918, Part D.—Issued by the Geological Survey, Ottawa; 15 pages, index and cover; 6½ by 9¾ ins.; includes reports by E. L. Bruce, F. J. Alcock and W. A. Johnston on various districts in Manitoba, including report of the superficial deposits and soils of the Winnipegosis area.

Summary Report, 1918, Part E.—Issued by the Geological Survey, Ottawa,; 32 pages, index and cover; 6½ by 9¾ ins. This booklet contains reports by E. R. Faribault and A. O. Hayes on investigations in Nova Scotia and New Brunswick, and report by A. Anrep on peat investigations in New Brunswick.

Summary Report, 1918, Part C.—Issued by the Geological Survey, Ottawa; 48 pages, index and cover; 6½ by 9¾ ins. Contains reports by F. H. McLearn, J. A. Allan, B. Rose, D. R. Dowling and J. Stansfield, on geology of various districts in Alberta, gasoline and natural gas in Alberta, and surface deposits of southern Saskatchewan.

Load Concentrations on Steel Floor Joists of Wood Floor Highway Bridges.—By T. R. Agg, highway engineer, and C. S. Nichols, assistant director, of the Engineering Experiment Station of Iowa State College of Agriculture and Mechanic Arts; issued as Bulletin 53 of the Good Roads Section of the Station; 32 pages and cover, 5¾ by 8½ ins.; illustrated.

Road Material Surveys in the City and District of Montreal, Que.—By Henri Gauthier. Published as Memo 114 of the Geological Survey, Ottawa; 47 pages, index, folded map and cover, 6½ by 9¾ ins. The booklet includes discussion of the conditions affecting road construction, the geology of the district, road materials (bed rock, field stone, sand and gravel) results of laboratory tests, list of and data concerning deposits of bed rock and field stone. It is illustrated by a few views of local quarries.

The next convention of the International Association of Fire Engineers, which is to be in Toronto, will probably be held in June, 1920. It will be the first time in 25 years that this association has held its annual convention in Canada.

A series of lectures on municipal government will be given this winter at McGill University. These will deal with various phases of the subject, including municipal government in Canada, Europe and the United States. The lecturers are Senator L. O. David, Dr. H. L. Brittain, Thomas Adams, C. R. Woodruff, Dr. J. A. Hutchinson, Frederick Wright, Oscar Moran, K.C., C. J. Yorath, C.E., Thos. Bradshaw, W. D. Lighthall, K.C., and Howard S. Ross, K.C.

G. A. Crain, of Ottawa, honorary treasurer of the Association of Canadian Building and Construction Industries, has issued his report covering (1) the Ottawa conference, November 26th to 28th, 1918, and (2) the period from December 1st, 1918, to September 30th, 1919. During the first period there was collected $1,060.34, and the expenditures amounted to $1,012.83. During the second period the receipts were $3,038.71 and the expenditures $2,777.03. The principal items of expenditure during the second period were the salary and expenses of the former paid secretary, A. S. Clarson, of Montreal, while the expenditures during the first period were entirely in connection with the general conference at Ottawa.

MOUNTAIN HIGHWAYS AT HAMILTON, ONT.

Report Submitted by Noulan Cauchon, of Ottawa, Plans Access to Stadium and Park Development with Ruling Grade of Three Per Cent.

AT the request of the city council of Hamilton, Ont., Noulan Cauchon, of Ottawa, consulting engineer and town planner, has presented a report outlining the development of the "Mountain Top" and planning highway approaches. Mr. Cauchon's report is accompanied by a plan showing a 3% grade to the proposed stadium and park development on the heights overlooking Hamilton. Following are excerpts from Mr. Cauchon's report:—

The Mountain Park of Hamilton is a rare natural health resource of exhaustless value to its citizens. It is the city's great playground—its training camp of potential energy and efficiency. Town planners and sociologists, all those concerned in the welfare of the public, no longer look upon parks as mainly ornamental features to a city, but as being of essential economic necessity in fostering and sustaining the development of human energy and efficiency in the rising generations, who are the citizens and workers of to-morrow. The mountain face park stretches for five miles along a populous area, but is separated from it in large measure by a railway barrier which denies to much of this population the free enjoyment, the recuperation and enhancement that is within its gift, and theirs by right.

Lack of easy access for attaining its benefits, lack of ease in surmounting, its almost impassability to normal traffic seeking its summit, have deprived this marvellous asset from benefiting the dwellers at its base and from fostering the expansion of life upon the very attractive and desirable tableland stretching back from its summit.

Railway Tracks Retard Development

The obstacle retarding development has been primarily the railway trackage upon and along a considerable stretch at the base of the mountain, with level crossings at rare and distant intervals—instance the distance of two miles from Wentworth to Kenilworth Ave., with only one, a level, intermediate crossing over the multiple tracks of the Toronto, Hamilton & Buffalo Railway at Ottawa St., and at that within half a mile of one end of this stretch, and on the Grand Trunk Railway Co.'s mountain line, only a level crossing about opposite the previously mentioned one, and one other, also level, approaching "incline." This abnormal state of affairs, further, has prevented the adequate development of roads for access and for overcoming with reasonable grade the declivities within the physical limitations of the site, the legal road allowances, moreover, having been largely projected straight up the hill at impossible angles.

New Road System

A system of roads has been devised and their grades determined to facilitate the transmission of city traffic to and from the mountain top. Moreover, this road system will enable access for the enjoyment and for the further development of the park, as such, and of its amenities. An easy and ruling uniform grade of 3% has been obtained not only throughout the main arteries, but also realized throughout the minor tributaries, this notwithstanding the necessity of adjusting numerous road junctions within the limits of this grade, and of finding fortunate turning points throughout free from the large areas of steep side hill. The subsequent work of building these roads will in general not entail any abnormal cut and fill beyond the usual well-balanced cross-section. There will be some heavy cutting at the approach to the summit, where routes have been concentrated from the various tributaries into one main deep portal through the brow of the mountain in the hospital grounds.

Recommends Immediate Trail Construction

I strongly recommend, as a means of enabling the public immediately to realize their heritage in the park, that a selection from the grades forthwith be opened progressively as narrow footpaths to begin with, thus giving prompt access for inspection and use by the citizens, that they may see and understand the problem and its solution; also that they may begin to enjoy the wide vision of city and hills and valley and lake, and determine to their satisfaction the needed progression in widening the trails into arterial highways.

Attention is drawn to the manner of road junction that eliminates or reduces to a minimum what are known as "collision points," and also to the advantages derived from making turning points level, so compensating for curvature and diminishing resistance to pull; in other words, increasing the tractive capacity and the loads which may be hauled up these hills with any given power.

The Railway Tracks

The elimination of the railway trackage within and along the base of the Mountain Park is now under consideration by the Dominion Railway Board. For the purposes of this highway report these tracks are taken as they stand and under or over crossings of the railway suggested, as seem necessary under the circumstances and merits of the case, to maintain a ruling grade of 3%.

Justification for Ruling Grade

The adoption of this 3% ruling grade claims justification by factors of height, distance, haulage, capacity, climatic effect on surface, and the exigencies of pavement, of ideal residential area development, of attainment of park facilities—in sum, justification on the broad and comprehensive principle of civic enhancement and amenity.

Grade Separation

Of the two grade separation schemes heretofore considered by the city in relation to James St., I hold the alternative one of track depression as therein submitted to be the lesser evil of the two, in the city's interest, but even at that not depressed enough.

Under the modern dispensation of motor transport, a city should claim the right to protection of its factor of haulage efficiency, the ruling grade of its arterial highways, as determined within and without. In grade separation schemes through cities, the principle of respecting the ruling grade of the arterial highways and main streets should prevail on its merits of paramount public importance. To date, the tendency has been unquestionably to allow railways their ruling grade, adjusting that of the community as of minor importance, usually at 5%. Where economically possible, both ruling grades should be attained; otherwise the disabilities, like the whole costs, be distributed proportionately on their merits.

Further, whilst the grade of a street at a given point may be altered without lessening its ruling grade of the whole artery, yet it may cause locally serious disfigurement, depreciation of property values and of amenity.

In a comprehensive scheme of grade separation throughout Hamilton as may be submitted by the railways in balance against their removal, as is now sought by the city, there should be no question of kinking or humping a number of the principal streets of the city.

Advocates Removal of Tracks

This dissertation on comparative evils in no way alters my firm conviction that the proper and most advantageous solution for the city is to labor and negotiate towards their removal, saving such spur connection as may be necessary for maintenance of existing industrial service.

Grade separation, at its best, will eliminate but life danger, one only of the many afflictions that evolve from the strenuous activities of railways in the wrong place—injuriously affecting general well-being.

Poor's Manual will give you detail as to the worthy stature enjoyed, as a private corporation, by the Toronto, Hamilton and Buffalo Railway, and, let me add, through able, courteous and effective management—yet the city of Hamilton embodies an aggregate corporate entity of about

a hundred millions of dollars, representing public interest and as of paramount importance, where a benefit or an injury to a part is a benefit or an injury to the whole.

The 3% Highway Grade

The city is well within right and fairness in claiming reservation for itself of a 3% grade as against the 1% prevailing on the railway. The 3% grade adopted for this sytem of roads was arrived at by first determining the objective points and their relative elevations. This means by finding a central common controlling point of highest city elevation and joining it in the most direct and continuous manner with the lowest central controlling common point of mountain tableland elevation.

Climatic Conditions

The climatic conditions of generally mild winters, little snow, occasional rain and intermittent freezing result in frequent periods of glare ice on the mountain grades.

I have observed the general difficulty, often impossibility, and the ever-constant danger of negotiating the existing mountain grades—even motor chains unable to grip —and there is a chapter of fatal accidents to their discredit.

Surface Paving

Steep grades as now existing preclude satisfactory paving and efficiency in maintenance. Observation of traffic on John St. in the vicinity of the Arkledun turn, in bad or frosty weather is convincing proof of the futility of smooth permanent pavement on such heavy grades.

Observation of the lack of pavement under similar conditions, say, the Jolley Cut, shows that rain and drainage scour the unprotected surface and materially heighten its resistance to traffic.

Three per cent. grades would allow of permanent pavement to the minimum of inconvenience and danger and maintenance, to the maximum of comfort, safety and tractive efficiency.

Importance of Motor Traffic

The advent of mechanical transport has brought the problem of highway haulage under the same principles for economy and efficiency as heretofore prevailed for railways and upon which railway grade reductions are figured and justified.

The "Good Roads" efficiency for mechanical transport is the beginning of what might be termed the democratization of transportation—independence for the individual.

Whoever owns a boat may place it upon water with the freedom of the seas, and compete in the markets of the world. Whosoever owns a motor truck may, in the near future, place it upon a national highway and compete freely for the traffic of the country. This already obtains between Toronto and Hamilton as the index of coming expansion, and is welcome warning to the community that it carefully nurse the efficiency of its public highways.

There are said to be 5,000 locomotives in Canada, also 250,000 automobiles (including motor trucks). If the number of locomotives be multiplied by 300, it would represent 1,500,000 h.p. hauling all the passenger trains and freight of Canada. If the autos and motor trucks be averaged at 20 h.p., it would represent 5,000,000 h.p. on our highways.

Trailers in the Future

Now, whilst this illustration is given with the candid admission that auto power to date is largely light traffic, yet it points to the growing power on our highways and to the future doubling, trebling, quadrupling, within measurable grasp, of motor traction and the economic advantage of its use with trailers.

Whilst disclaiming any inherent virtue in any particular grade, except in its relation to the economics of any particular case, on its merits, the fact stands out that the future of highway transportation enjoins upon cities the responsibility of determining at least the best ruling grades that its circumstances afford, and justifies communities in claiming that such be absolutely respected in any intersection with any railway or other transportation device.

Reverting to Hamilton: A good five-ton motor truck will barely haul itself and load up the "Jolley Cut." The same motor truck would haul itself and load and three trailers up the proposed mountain grades, in all 15 to 20 tons, according to surface conditions.

If the building up of the Mountain Top as a suburb be considered, this means cutting to a third, or better, the cost of delivering up there all bulk materials, brick, sand, lumber, coal, etc. This means cheaper "housing" and keeping down the capitalization of the "home."

These 3% grades also mean that degree of efficiency in the radiation of Hamilton's highways to all the country between it and Lake Erie; increasing the quantity and lessening the cost of produce receivable, lessening the cost of long haulage and expediting the city's industrial production.

Town Planning and Arterial Highways

The synthesis of organic town planning is, first, solution of the railway problem; secondly, determine arterial highways; thirdly, zoning, that planning may be to purpose.

Regarding the great provincial arterial highways and their subsidiary collection and distribution of the traffic they carry, it may be well to note that the motor world is coming to accept the 5-ton truck as the standard haulage unit.

This truck can be unwisely overloaded to 7 tons; it can be made advantageously to haul 4 trailers on level roads, an aggregation of 25 tons. Individual or special trucks or trailers will be loaded with boilers, machinery, and other items exceeding 10 tons.

It is manifest that a city cannot rovide all its pavements for the indiscriminate admission of such loads, and must determine certain routes throughout its mesh of streets for heavy haulage with special foundation and maintenance for same, or risk having all its pavements in a generally crushed and disintegrated state.

Anticipating such routing (a further argument for zoning), I have endeavored to provide a level road across the base of the park, south of the present Toronto, Hamilton & Buffalo trackage, as a collecting channel for the main north and south heavy arteries, which are about half a mile apart—Kenilworth, Ottawa, Gage, Sherman, Sanford, Wentworth, Victoria, Wellington, and the principal streets between this latter to and including James, in the present report. These arteries will no doubt in time come to be dedicated for heavy traffic bearing and be provided with deep concrete bases.

May Expropriate Railway's Land

A peculiar situation arises in connection with the mountain base road referred to, being that not only would an extension of Kinnear Yards, as previously attempted, prevent the carrying out of this provision, but that the further use of the adjacent property by the Toronto, Hamilton & Buffalo Railway Co., and now owned by them, would also prevent proper access to the whole Mountain Road system for nearly a mile and a half between Ottawa and Sanford Aves.

It may be that this land outside of the right-of-way which may be taken by franchise is still but railway real estate, and, failing its having been authorized by the Dominion Railway Board as "extra land," can be taken by the city under the ordinary provisions of Municipal Act for highway and for park purposes. In any case, the matter should be submitted to the Dominion Board for discussion and authorization of the road system as road diversions, and for protection of necessary supporting physical conditions for accomplishing same.

Park Development

The topography of the Mountain Park is such that its natural treatment will be one of terraces. The road system proposed for economic purposes so happens to be admirably adapted to further this particular style, for which the park contains many magnificent opportunities.

The street railway tracks on the two main grades from James and from Kenilworth Streets should, where within the park, be at the curbs, in order that passengers may enter and leave anywhere without slowing or interrupting the passing motor traffic.

PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSING OF TURBINE GATES*

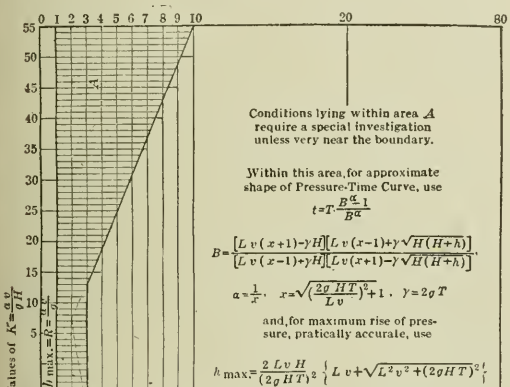
By R. D. Johnson
Consulting Engineer, New York City; Formerly Chief Engineer, Ontario Power Co., Niagara Falls, Ont.

MR. GIBSON'S remarkable paper deserves the closest attention on the part of all who are interested in the water-hammer problem.

He remarks that the theory has not been experimentally confirmed, but it is so obviously complete and correct as scarcely to need such confirmation to establish strong faith in its accuracy.

The writer has been especially interested in a completely correct treatment of this subject, in order to be able to fix the limits of K within which his pressure-time curve, previously presented to the American Society of Civil Engineers, is sufficiently accurate for practical purposes.

It is found, fortunately, that this smooth curve†, log. $x = n$ log. $[T/(T-t)]$, is applicable with much precision to such a wide range of conditions as to justify its use for practically all the water-hammer problems arising in connection with the design and operation, under ordinary heads, of water turbines, when properly regulated.



Conditions lying within area A require a special investigation unless very near the boundary.
Within this area, for approximate shape of Pressure-Time Curve, use
$t=T\frac{B^{\alpha}-1}{B^{\alpha}}$
$B=\frac{[Lv(x+1)-\gamma H][Lv(x-1)+\gamma\sqrt{H(H+h)}]}{[Lv(x-1)+\gamma H][Lv(x+1)-\gamma\sqrt{H(H+h)}]}$
$\alpha=\frac{1}{x}$. $x=\sqrt{(\frac{2gHT}{Lv})^2}+1$. $\gamma=2gT$
and, for maximum rise of pressure, pratically accurate, use
$h_{max.}=\frac{2Lv H}{(2gHT)^2}\{Lv+\sqrt{L^2v^2+(2gHT)^2}\}$
or $=\frac{HK}{8n^2}\{K+\sqrt{K^2+16n^2}\}$
Within this area, for maximum rise of pressure, use
$h_{max.}=\frac{H}{2}\{K^2r^2+2K-\sqrt{K^2r^2(K^2r^2+4K^2+4)}\}$
$r=\frac{n-1}{n}$
Values of $K=\frac{av}{gH}$
Values of n

FIG. 12—CHART OF LIMITATIONS FOR WATER-HAMMER PROBLEMS

By differentiating Mr. Gibson's equations, it is possible to express rigidly correct values of the tangents to the true pressure-time curve at (a), the beginning of gate closure (b), the end of the first interval, and (c), the beginning of the second interval.

Using Mr. Gibson's nomenclature, with omission of subscripts, that is, putting $R_0 = R$, and $S_{T1} = S$, and $H_0 = H$, these tangents may be expressed as follows:—

tan. (a) $= 2RH/(R+2H)T$

tan. (b) $= [R^2(T-T_1)/HT^2]\{(S+2R+2H) \div [S(S+4R+4H)]^{1/2}-1\}$

tan. (c) $= [R^2(T-T_1)/HT^2]\{[S(Z+1)+2R+2H] \div [S(S+4R+4H)]^{1/2}-(Z+1)\}$

where $Z = 4H^2T/R(R+2H)(T-T_1)$.

It is clear that the effects of vibration in the water column, due to elasticity, tend to disappear when the conditions are such that tan. (b) and tan. (c) approach equality; also, if the change in the rate of pressure rise at the beginning of the second interval, due to the effect of the returning wave, is less than the rate at which the pressure begins to rise

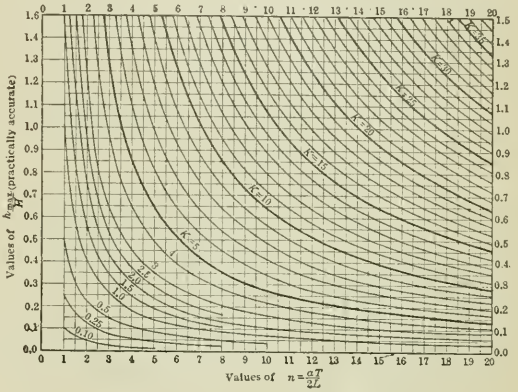


FIG. 13—WATER-HAMMER CHART FOR UNIFORM GATE CLOSING

when the gate starts to move, it is evident that the conditions are such that the effect of elasticity is rapidly dying out, and that it should be scarcely appreciable during the remainder of the closing period.

If, then, tan. (b) — tan. (c) < tan. (a), the writer's Equation (7), above referred to, or the maximum value of h, given by the so-called Alliévi formula, may be used with much precision.

This may be shown to be the case when.

$$K > 2/[(3r^2+1)^{1/2}-1] \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where r is the ratio $(T-T_1)/T$; and $K = R/H$.

Equation (1) marks the lower limit for values of K, below which it is not safe to use Equation (7). To find the upper limit of safety, for values of K, it is noted that, as H decreases, the pressure-time diagram passes through a transition stage where an ogee form of curve most closely approaches to a straight line, and, that thereafter, as H continues to decrease, Equation (7) begins to produce a curve sharply upturning and curving one way, for the most part, as its extremity reaches toward infinity, thus leading to serious errors in its results.

By trial, assisted by arithmetic integration, it has been noted that, for large values of n, the head may be reduced to about one-half the value which produces the approximate straight-line diagram.

To find this point we may equate the value of $h_{max.}$ in the so-called Alliévi formula to the value of the pressure rise found at the end of a straight-line pressure-time diagram, enclosing the same impulse area, and solve for the value of H.

In this way it is found that

$$K = 3n \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

(where n is the closing time expressed in intervals), and Equation (7) may be used so long as

$$K \leq 6n^2/(n+1) \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

which, for large values of n, is nearly twice as great as the value given by Equation (2), but which becomes equal to 3, as it necessarily must, when n becomes unity.

*Discussion (presented to the American Society of Civil Engineers) of Norman R. Gibson's paper (see September 4th and 11th issues of *The Canadian Engineer*).

†The derivation of this curve, Equation (7), is given in Transactions, Am. Soc. C.E., Vol. LXXIX, p. 280.

Equation (3) marks the upper limit for values of K, above which it is not safe to use Equation (7). Therefore, the smooth logarithmic curve given by Equation (7) may be applied only when K lies between the values given in Equations (1) and (3), and preferably, also, when n is not less than three intervals.

Fig. 12 shows that Equation (7) covers a very wide range of conditions, and, furthermore, in the design of a water-turbine installation, the values of V and n should, when possible, be adjusted so that Equation (7) will be correctly applicable; and particular attention should be given to the limitations set forth in Equations (1) and (3), in order that the speed of the water unit may be regulated most effectively.

The expressions for the tangents (a), (b) and (c), are rigidly accurate, and form a substantial basis for further possible study; for example, if tan. (c) be equated to zero, the limiting value of n may be found when the maximum pressure-rise occurs at the end of the first interval. This is thus found to be the case, always, when

$$n > (4K^2+8K)/(12-K^2-K^3) \quad \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

It is seen that this expression is positive and finite only so long as $K < 2$; therefore, K must always be less than 2, in order that the maximum rise shall occur at this point. It does not follow that this will be the case merely because $K < 2$, unless Equation (4) also applies.

In support of Mr. Gibson's work by experimental observation, it may be pointed out that much information is available for cases which occur within the limits here set forth, and, inasmuch as his complete work incidentally includes such cases, it may safely be predicted that no error in theory will be discovered by experiment.

The writer, himself, has confirmed Equation (7) a great many times, under a variety of conditions, in the past twenty years, and, because of such confirmation, he was not led, from practical necessity, to a more thorough investigation of the theory.

In conclusion, the writer wishes to urge those interested to a further study of the limits here graphically presented, with the idea either of confirming or improving them, because it is not profitable to resort to the very tedious processes incident to the methods presented by Mr. Gibson, except when a comparatively simple formula is inapplicable. The chart, Fig. 12, indicates that this is very rarely the case, and practically never need be, with proper care in the design and operation of any water system.

It is interesting to note that Mr. Gibson's methods may be used to work out a system of perfectly general cases, thus enlarging, indefinitely, the scope of such diagrams as he has presented, which are based, merely, on a specially selected set of data.

This is made possible by simply substituting in his scale of ordinates, values of the ratio $(h_{max.}) \div H$ in place of (h_{max}), and substituting for the values of H, written on the curves, the values of K.

This trifling change, it will readily be seen, will make such diagrams applicable to an infinite variety of special cases.

In this manner, the chart, Fig. 13, has been roughly prepared, and, for the range of values covered, it is not necessary to resort to formulas.

All combinations of a, V and H which produce a constant value of K must invariably result in a definite single value of the ratio $(h_{max}) \div H$ for each selected value of n. Therefore, in fact, each point of the chart covers, theoretically, an infinite variety of conditions.

In the use of the chart or simple formulas to replace the accurate but tedious methods, it should be borne in mind that it is not ordinarily practically necessary that the agreement should be perfect, because, as Mr. Gibson has shown, the shape of the curve is so sensitive to the vagaries of the gate motion, in closing, as to make it almost out of the question to reproduce, experimentally, any definitely selected shape of curve; so that, after all, the element of judgment must enter as usual.

The effects of velocity-head and friction-head have been neglected in the preparation of Figs. 12 and 13. These factors are nearly always of minor importance, as affecting the rise of pressure, but, nevertheless, they may be taken into account by means of arithmetic integration in special cases where great accuracy is thought to be warranted. These effects, at any rate, cannot be included in a usable formula, covering the whole range of the charts.

DEAN MITCHELL INSTALLED AT TORONTO

Discusses Trend of Scientific Education and Indicates Probable Broadening of the Curriculum—Greater Attention to be Paid to Certain Civil Engineering Subjects

DECLARING that the aim of university education to-day should be to produce broadly educated, cultured gentlemen and good citizens, even before the production of trained technologists, Brig.-Gen. C. H. Mitchell, C.B., C.M.G., D.S.O., delivered an interesting address on Wednesday of last week, at Convocation Hall, Toronto, at his installation as dean of the Faculty of Applied Science and Engineering of the University of Toronto.

The new dean was introduced by the president of the university, Sir Robert Falconer, who, after speaking with high appreciation of the work of the two former heads of the faculty—the late Dean Galbraith and the retiring Dean Ellis—referred to the development necessary if the engineering faculty is to march with the times.

University Must Anticipate Demands

In introducing Dean Mitchell, Sir Robert said: "On the new dean rests a particularly heavy responsibility, and I believe we have the man to shoulder the responsibility." Sir Robert then spoke at length of the brilliant war record of Dean Mitchell, and said that the qualities which had made him so successful in war, were those which would make him successful as dean. In conclusion, Sir Robert expressed his gratitude to Dean Mitchell for his acceptance of the responsibilities attaching to his new office, and, as president of the university, formally asked him to make his inaugural address.

Dean Mitchell, who rose amidst enthusiastic applause from the students and members of the faculty present, commenced by paying a warm tribute of appreciation and affection to Dean Ellis and to the memory of the late Dean Galbraith, to whose splendid work he attributed much of the success which the Faculty of Applied Science has already attained.

Taking as the subject of his address, "The Future of Applied Science," Dean Mitchell declared that this rests with all who are concerned with the development of this great country, not only in the actual processes, but equally in the education of the young men who are to participate in its development. It is not sufficient to "wait and see" what the trend of events will be, but it is for the university to anticipate the requirements and demands and to have ready the highly educated and trained men to meet the country's needs. The highest function of a university, he declared, is to lead the country in thought and action.

Influence of the War

Turning to the influence that the war has had upon the lives and ideals of men who have served in it, the speaker referred to the important part that engineering science played in the war, recalling the words of Lloyd George early in the struggle, that it was an engineer's war. Dean Mitchell, in proof of this, reviewed some of the contributions of science to the success of the struggle, referring to the elaborate developments in trench warfare, in artillery, in the air and under the sea.

"There is a new world ahead in applied science," he declared, and pointed out that Canada has realized the greatness of her resources during the war, and her ability to apply

them to her own life and the life of the Empire. The speaker saw ahead a great resumption of manufacturing and industrial activity in the country and a great need for the services of many applied scientists and engineers.

Discussing the educational requirements to meet this demand, Dean Mitchell saw a greater need for training in the industrial group of electrical, mechanical, chemical and metallurgical engineering work. An interesting fact is observable in the present year at the university, where one-quarter of the new students in the engineering faculty are in chemical engineering.

Dean Mitchell then discussed the tendency of scientific education to become too specialized, though this had not been the case so much in Canada. He declared that the first principle in applied science education is undoubtedly that a sound general education should be obtained as a foundation.

"Thirdly,—Educated Technologists"

"Considering the entire education of the young engineer," he continued, "there seems only one conclusion as to the necessity of to-day in this young country at its critical stages of development. For nowadays we require not only technologists in the form of applied scientists or engineers, but we want men who are more than that—we require to produce men who by their college education will be: First, broadly educated, cultured gentlemen; second, good citizens of Canada and leaders of influence within the community in which they may be placed; and after this, third, thoroughly educated technologists in whatever branch of applied science they may chance to enter."

How to obtain these results next occupied the attention of the speaker, and he referred to the returned soldiers present among the students, who would look to have the great principles of science that played so important a part in the war, applied in an even greater measure to the problems of peace. The curriculum under which the students studied would need radical changes designed primarily to broaden the present educational outlook of the "science" student.

Greater Attention to These Subjects

Referring to the actual engineering teaching itself, the speaker showed how greater attention will have to be paid to such subjects as municipal and sanitary engineering, transportation and highway engineering, irrigation engineering, aerodynamics, shipbuilding, architecture and town-planning.

In order that the science student may go out into the world a practical man in touch with the full life of industry, Dean Mitchell thought that such questions as the philosophy of values and costs, the psychology of labor and industrial problems, should be taken up during his training. If the engineer and the applied scientist are to take their places in the community, they must be trained to appraise correctly what men consider worth while, he declared. Dean Mitchell concluded by impressing upon his audience the fact that character and personal qualities rank above mere technical knowledge.

"A hardening solution for concrete floors that prevents dusting is made from sulphate of alumina and acidulated water. To 10 gals. of cold water (as soft as possible) add slowly 1 fluid ounce of commercial concentrated sulphuric acid. Heat the liquid to boiling point and stir in gradually 25 lbs. of commercial sulphate of alumina. When this solution has been effected let it cool and settle for several hours. Strain through muslin. The concrete surface to be treated must first be swept and thoroughly washed. After drying, the hardener is put on, preferably with a broom. Four applications are recommended; three consist of varying dilutions of the hardener with water, while the fourth is the hardener used 100% straight. These first three solutions are respectively: (1) 30 hardener to 70 water, (2) 50-50, and (3) 70 hardener to 30 water. Allow an interval of twenty-four hours between successive applications. The above quantity suffices for the complete treatment of an area of from 50 sq. yds. to 100 sq. yds., depending upon the porosity of the surface treated."—From the Municipal Engineering and Sanitary Record, England.

THE PROSPECTS OF RAILROAD ELECTRIFICATION

By F. H. Shepard
Director of Heavy Traction, Westinghouse Electric & Manufacturing Co.

WORLD-WIDE shortage of coal during the great war has emphasized more clearly than ever the necesssity of fuel economy in industry, while the present shortage of labor and the certainty of its continuing scarcity throughout the reconstruction period, forms another most serious problem. But fortunately we have at our disposal a means that will greatly assist in alleviating both of these conditions, namely—electrification.

The use of electricity in industry saves both fuel and labor. This fact is recognized throughout the world to-day, and in order to secure these advantages, practically all of the nations are now considering plans for the electric generation of power. In England, Belgium and France, among others, these plans are being prepared by official commissions, so a tremendous activity in electrical power development may be expected with the stabilization following the advent of peace. In all cases, the ideal in view is a broad one: To use electricity for all possible power purposes, including railroad operation.

Advantages of Electrification

The operation of the railroads will naturally form an important part of any program of general electrification, for in almost every country the railroads form one of the largest users of fuel and labor. Nor are the advantages obtained from railroad electrification limited solely to economy in fuel consumption and the more effective use of labor. Among others, the following may be mentioned:—

1.—Greater speed of movement for the heavier trains, due to the fact that electric locomotives can be made much more powerful than the largest steam locomotives.

2.—Greater nicety of control.

3.—Increased traffic capacity of existing tracks, terminals, grades, tunnels and other points of traffic restriction. When electricity is used, heavier trains can be operated at higher speeds and less time is consumed at terminals and in yards.

4.—Operation where the use of steam is impossible or objectionable, as in long tunnels.

5.—Independence of weather conditions, since the electric locomotive is not affected by cold weather.

6.—More reliable operation, as proved by the statistics of all existing electrifications.

7.—More effective use of all rolling stock, due to more expeditious movement of traffic.

Those are some of the advantages that are now being obtained by the mere substitution of the electric locomotive for the steam locomotive, but they by no means tell the whole story.

Unlimited Inherent Possibilities

Consider electric illumination. When first introduced, the electric lamp supplanted a gas or an oil light because of certain advantages it possessed, and at first it occurred to no one that it would ever do much more. But within 30 years the electric lamp has revolutionized illumination and has given us our light-flooded factories, with their greatly increased production and safety, and our "Great White Ways" also.

The industrial electric motor is another case in point. At first it merely took the place of a steam engine in the factory. To-day, practically every machine has its own motor of specially selected characteristics, and feats of production are now possible that were undreamed of a generation ago.

A further example is the growth of our great city and interurban electric transportation service of to-day due to the substitution of the electric motor for the horse on street cars.

In other words, an electrical method will in the beginning take the place of an older practice because of some economic superiority. Then its almost unlimited inherent possibilities are developed, and in time results are accom-

plished that would be impossible at any cost with the older methods.

There is good reason to expect that the electric operation of the railroads is capable of a similar development and will in time revolutionize our present transportation methods and provide us with services we know little or nothing about to-day.

Conditions in United States

Since the United States has an abundance of coal, railroad electrification there has been determined solely by local conditions. Passenger terminal problems caused the electrification of the New York Central at New York and of the Pennsylvania at New York and Philadelphia. The limitations of the steam locomotive determined the electrification of the Baltimore Tunnel on the Baltimore & Ohio, the Cascade Tunnel on the Great Northern, the St. Clair Tunnel on the Grand Trunk, the Hoosac Tunnel on the Boston & Maine, and the Detroit River Tunnel on the Michigan Central. Examples of electrified railroads with freight as well as passenger service are the Norfolk & Western; the Chicago, Milwaukee & St. Paul; and the New York, New Haven & Hartford.

While the other electrifications are successful and interesting, the last three are more properly representative of general railroad electrification. The Norfolk & Western is an example of electrification under the heaviest conditions of freight traffic on a mountain grade. The Chicago, Milwaukee & St. Paul has in operation the longest continuous mileage in the world, and when completed will cross five mountain ranges. The New York, New Haven & Hartford has a very large movement of both freight and passenger traffic.

All three installations are successful and profitable and, when financial conditions are stabilized and the American railroad question settled, it is expected that all three will extend their electrified service.

In addition, there are sections of railroads, in various parts of this continent, where the present congestion of traffic or the availability of water-power warrants the early adoption of electric power. Under normal conditions of finance, as no engineering problems now remain to be solved, these possibilities alone promise extensive activity in the electrification of railroads for many years to come.

Conditions Abroad

Differing from North America, European and South American countries, with the exception of England alone, lack an adequate supply of fuel, but many of them, including Norway, Sweden, Switzerland, Italy, Spain and Brazil, have large amounts of water-power, while France has a moderate amount. These resources, combined with the high cost of fuel, make extensive railroad electrification in these countries inevitable sooner or later.

The neutral countries will probably be the first to undertake this work, Switzerland having a well-established program covering a term of years, while both Norway and Sweden are giving active consideration to definite projects.

In England, a considerable amount of electrification is in contemplation along with the general plan for the electrification of industry.

A French commission composed of government and railroad engineers have already visited the United States in order to familiarize themselves thoroughly with American practice.

The Italian government will continue their definite program as soon as financial conditions permit.

An official Belgian commission is already planning to rehabilitate with electric power at least a portion of the railroads destroyed by the Germans.

In Spain, Brazil and South Africa, railroad electrification is under active consideration.

It is evident, therefore, that the next decade will see a large amount of railroad electrification in almost every quarter of the world.

The next (second) general conference of the Association of Canadian Building and Construction Industries will be held in Ottawa beginning January 20th, 1920. The association will also hold a convention next month in Winnipeg.

RULES FOR DRAFTING PRACTICE

Cover Concisely Dimensions of Drawings, Allowable Scales, Character of Lettering and Many Other Points

SOME ten years ago H. N. Savage, then with the United States Reclamation Service, and now hydraulic engineer for the city of San Diego, Calif., drew up the following rules regarding drafting practice. They have been in use ever since on his projects, with excellent satisfaction, says Engineering News-Record, of New York:—

Drawings should conform to the following sizes, several sheets being used if necessary, supplemented with an index sheet:—

Out to out.	Inside border.
8 x 11 ins.	7 x 10 ins.
11 x 16 ins.	10 x 15 ins.
16 x 22 ins.	14½ x 20½ ins.
22 x 32 ins.	20½ x 30½ ins.
32 x 44 ins.	30½ x 42½ ins.

Drawings of 10-in. vertical dimension, inside border, may be made any length necessary over 15 ft.

Trimming lines for drawings should be drawn on each tracing and the tracing cut ¼ in. outside these lines. Paper drawings should be cut to the same dimensions as tracings.

Tops of drawings should orient with north cardinal point.

Maximum dimension of drawings should be horizontal.

Do not abbreviate any words on drawings.

Sufficient legends should be used to identify all parts of a drawing.

Drawings must be independently checked with a degree of accuracy commensurate with the importance of the work involved.

The initials of the persons who draw, trace and check a drawing should be shown in the lower left-hand corner thereof. Those of the checker should be affixed by him in writing; the others should be printed.

The names of the supervising and project engineer or engineer in charge should appear on all drawings, but may be printed on drawings not requiring approval. Drawings of projected work and drawings involving policy, after being signed by the project engineer or engineer in charge, and before construction is begun, must be submitted to the supervising engineer, and if they are approved separate prints will be furnished to the project or feature office. Approved tracings will usually be retained in the files in the supervising engineer's office.

The subject of the drawing should form the major feature of the title, as, "Lower Yellowstone Dam." Such words as "map," "plat," "sketch," "location," "proposed," etc., should not be used in titles.

Drawings accompanying correspondence should be stamped on the margin "Transmitted to .....with letter dated .....19..," or, "Received from..... .....with letter dated .....19..," appropriate name and date being written in ink.

Paper drawings and prints should be folded right side out to letter size, title on top.

Only a minimum amount of work should be done on pencil drawings which are to be traced. Whenever practicable, preliminary penciling should be done directly on the tracing cloth.

Every tracing, in advance of its making, should receive an appropriate title and project number. Project and supervising engineers' file numbers should be placed on the margin in the lower right-hand corner.

Lettering on drawings should be placed to be read from the lower right-hand corner of the drawing. Plain single-stroke letters should be used except on drawings requiring distinctions between different kinds of names. Liberal and uniform spacing should be provided between words. Inclined Gothic lettering should be used on structural and mechanical drawings; capitals for special emphasis and in titles; lower case for general description and notes. Lettering on drawings 11 x 16 ins. or over should be of sufficient size to be

legible when the drawings are reduced to one-half the original dimensions.

Contract drawings, except profiles, for photolithographic reproductions should be prepared for a reduction to about two-thirds the original dimensions, and to come down to a vertical dimension of 10 ins. between the border lines. Profiles should be prepared for reduction to one-half the original dimensions, with a vertical dimension of 10 ins. between the border lines. Where possible, two lines should be placed on a sheet. The horizontal scale of profiles should be made as small as practicable. Lettering on contract drawings intended for photolithographic reproduction should be in pencil, the final lettering being left to be put on in the director's office with standard type.

Drawings of land should show legal subdivisions or other co-ordinate lines referred to some fixed point, as section or quarter-section corners.

True north, also magnetic north if known, should be indicated on each drawing of land unless section lines are shown.

Vertical sections and elevations taken across a stream or canal should be shown looking downstream. Vertical sections and elevations taken along a stream or canal should, wherever practicable, show stream flowing from left to right. Stationing of profiles should, wherever practicable, increase from left to right of the drawing.

The direction of streams and of canals through structures should be shown by arrows.

Contours should be in 1, 2, 5, 10, 20 or 100-ft. intervals. Contours and figures showing their elevations should be in burnt sienna. Distinguishing contours should be of deeper color.

Graphic scales should be shown on each drawing. Following are approved scales:—

For maps and allied drawings, 10, 20, 40, 100, 200, 400, 500, 1,000 and 2,000 ft. and ½, 1, 2, 5 miles, and even multiples of 2 and 5, to an inch.

For engineering structures, ⅛, ¼, ½, 1, 3 and 6 ins. per foot, and 10, 20 and 40 ft. to an inch.

For mechanical and architectural drawings, 1/16, 1/18, ¼, ½ and full size.

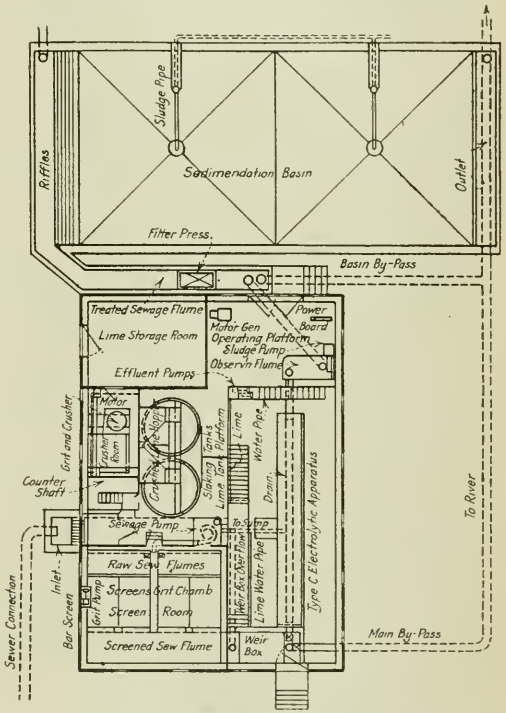
Following is a partial list of Canadian patents recently obtained through the agency of Ridout & Maybee, Toronto: Henry P. Fletcher, means for the conversion of water pastes into oil pastes by chemical and mechanical action; Jabez Muskett, hose couplings and hose attaching devices; Diaphone Signal Co., Ltd., metal bending and forming machine; Nile Testrup, methods of conducting high temperature reactions; E. O. Williams, slipways for the construction of reinforced concrete ships, barges and other floating structures.

The Portland (Oregon) Telegram announces the opposition of engineers of Multnomah County to the appointment of an eastern bridge engineer to design and construct several bridges in the city of Portland. The estimated cost of the bridge program is between $2,500,000 and $5,000,000. A number of Portland engineers appeared before the Board of County Commissioners and registered a protest against the plan to engage a Kansas City bridge firm to carry out the work. As a result of the protest, the Board of Commissioners asked the engineering societies of Portland to recommend an Oregon engineer who in their estimation is competent to undertake the entire program.

Two 25,000 k.w. steam-driven turbine units, which, when installed, will complete the largest steam-driven electrical installation in the Far East, are now being erected at Osaka, Japan, for the Osaka Electric Light Co. Located in an extensive industrial district, this company furnishes light and power to street railways, steel works, ship builders, copper refining plants, paper mills, electro-chemical installations and other industries. In 1908, the Osaka Co. installed three steam turbine units of 3,000 k.w. each. In 1910, two more units of like capacity were added, and in 1911 two, 5,000 k.w. units. The 25,000 k.w. units now being installed will bring the capacity of the plant up to 100,000 h.p.

OPERATING RESULTS OF "DIRECT OXIDATION" EXPERIMENTAL SEWAGE TREATMENT PLANT AT EASTON, PA.

IN November, 1917, the city of Easton, Pa., granted permission to C. P. Landreth, of Philadelphia, patentee of the "direct oxidation process" of sewage treatment, to construct an experimental plant for treatment of the city sewage. The plant was to have a nominal capacity of 1,000,000 gals. per day, and was to be installed without obligation on the part of the city. The plant was placed in operation shortly after May 1st, 1918. Tests of the experimental plant were conducted in December, 1918, by engineers of the State Department of Public Health, an 8-hour test run being made on December 4th, followed by a 24-hour test, starting at 8 a.m., December 6th. The results of these tests are given in a report by C. A. Emerson, Jr., chief of the Engineering Division of the Department. The matter following is an excerpt from this report:—



PLAN OF EXPERIMENTAL PLANT AT EASTON

The area tributary to the plant is divided into two distinct districts. The first is sewered on the separate system, contributing sanitary sewage only, while the second district contains combined sewers, contributing both storm water and sanitary sewage. A survey of the district indicated 585 properties connected to the sewer system as follows: 511 dwellings, 37 combined stores and dwellings, 10 stores, 2 office buildings, 3 hotels, 3 schools, 1 laboratory, 7 churches, 1 armory, 8 garages and 2 breweries. The order of the Federal Government closing breweries became effective four days previous to starting the test of the plant, hence the volume of manufacturing waste discharged from these breweries was much reduced.

The sewage received at the experimental plant appears to be a fresh, domestic municipal sewage of ordinary concentration and composition, and passes through a centrifugal pump before treatment.

The rainfall during the last part of November and the few days of December preceding the test was negligible.

The time of passage of sewage from the most distant house in the district to the sewage treatment plant is comparatively short, and probably does not exceed 1¼ hours. The low quantity of total solids, suspended solids and oxygen consumed indicate a relatively dilute sewage; the presence in appreciable quantity of nitrates and nitrites and the ratio between the organic nitrogen and the free ammonia contents show that the sewage is quite fresh as treated at the plant. The process of treatment at the plant consists of (1) coarse bar screens; (2) flat plate fine screens, ¼-in. circular openings; (3) grit chamber; (4) chemical treatment—3.720 lbs. lime per 1,000,000 gals.; (5) electrolysis; and (6) settlement.

Description of Plant

Sewage is diverted from 3 ft. by 4 ft. 6 ins. egg-shaped combined sewer through a 12-in. pipe, a concrete dam having been constructed in the main sewer immediately below the lateral. At the plant the 12-in. pipe discharges through a 10-in. valve into a covered flume 3 ft. 6 ins. wide equipped at its inlet end with a coarse bar screen for the removal of sticks and other large objects. The flume leads to the suction well of a 6-in. centrifugal pump which lifts the sewage about 14 ft. 6 ins. to a raw sewage flume, placed at such an elevation that the sewage can flow thence by gravity through the treatment plant. From this flume the sewage flows on to a horizontal flat plate screen with closely spaced holes ¼ in. in diameter, through which it falls into a hopper-bottomed grit chamber. The raw sewage flumes, fine screens and grit chambers are in duplicate, only one-half being used at a time. The screened sewage overflows from the grit chamber into the screened sewage flume, passes over a 3-ft. weir, is treated with a suspension of lime, and then passes through a 12-in. pipe to the electrolytic cell. From the cell the sewage flows through an open observation flume connected to the treated sewage flume, and thence over concrete riffles into the sedimentation basins. The two basins are connected in series, and have a combined capacity, to the elevation of the outlet weir of 88,740 gals., giving when clean a detention period of about 2⅛ hours on a flow of 1,000,000 gals. per 24 hours. A 4-in. sludge pipe is provided from each basin to permit of drawing the sludge onto two small sludge drying beds immediately east of the sedimentation basins.

The entire plant, with the exception of treated sewage flume, sedimentation basins and sludge beds, is neatly housed in a sheet iron building, 48 ft. 3 ins. long and 35 ft. 6 ins. wide. The difference in elevation between the fine screens and the overflow weir from the sedimentation basin is 5 ft.

By-pass arrangements permit of running screened or screened and lime-treated sewage from the weir box direct to the river, or of running treated sewage from the treated sewage flume to the river without passing through the sedimentation basins. An overflow pipe in the screened sewage flume diverts any excess over the capacity of the plant, returning it to the pump well. The low concrete dam in the main sewer permits the latter to take the entire flow when the pump is not operated or excess flow in time of storm.

Electrolytic Apparatus

The electrolytic apparatus is enclosed in a horizontal wooden tank, 27 ft. 3 ins. long, 3 ft. wide and 2 ft. 9 ins. high (outside dimensions), reinforced with steel plates and mounted on supports 18 ins. high. The 2-in. wrought iron vent pipes are carried up from the top of the tank for the removal of any excess gaseous products of electrolysis. A series of blow-out valves are provided along the bottom of the tank.

This tank contains 22 banks of plates, arranged in two layers of 11 banks each. Each bank of electrodes consists of 48 rectangular steel plates 16 ins. long, 10 ins. high and 3/16 in. thick, placed parallel to the sides of the tank, and spaced ⅜ in. apart. The plates are so connected that alternate plates have the same polarity, giving 24 pairs of plates connected in multiple in bank, the 22 banks being connected in series. Spaces between the banks and the sides of the tank are closed, compelling the sewage to flow through the ⅜-in. spaces between the plates. In each space between the plates two straight paddles of Bakelite are revolved, being attached to shafts passing through holes punched in the plates to receive them. The paddles are driven at a speed of 20 revolutions per minute by a 3-h.p. motor, the power being transmitted to the paddle shafts through suitable reduction gearing. The total number of paddles in this plant is 2,068.

At the normal rating of the plant, i.e., 1,000,000 gals. daily, the time of passage through the electrolytic cell is approximately 70 seconds, of which 17.4 seconds represent the time of contact with the electrodes, the remainder of the time being occupied in passing through dead space between successive electrodes. During contact the sewage travels in streams ⅜ in. thick for a distance of 14 ft. 8 ins. at a theoretical velocity of 0.84 ft. per second.

Lime Apparatus

Provision is made for using either lump or hydrated lime. When the former is used the lumps are broken by hand on a 3-in. grid placed over a crusher, which discharges into an elevator boot. When hydrated lime is used a spout delivers it directly into the elevator boot. The elevator discharges into an overhead hopper from which it is fed dry by adjustable feeding devices to the solution tanks.

The solution tanks are two in number, each 7 ft. in diameter and 3 ft. deep, each with an independent feeding device and agitator. Only one tank is used at a time.

The feeding device consists of a trough with a double worm feed actuated by a ratchet and pawls, which in turn are driven by a reciprocating link attached to an eccentric. The rate of feeding lime to the solution tank may be adjusted within certain limits by changing the throw of the eccentric and by varying the number of teeth engaged on the ratchet by changing the position of the pawl arm.

Either city water or plant effluent can be used in the solution tanks; when the effluent is used it is pumped by a motor-driven 1-in. centrifugal pump. In either case, the water enters the tank tangentially near the bottom to help the agitation and the lime suspension or milk of lime is drawn from the top of the tank. Agitation is by means of a two-bladed 10-in. fan placed at the bottom of the tank and operated at 900 r.p.m. by the 1-h.p. motor, which also drives the feeding device. The circulation is downward at the centre and upward at the sides.

Suitable piping delivers the lime suspension into either the spillway of the weir or the observation flume as desired.

Electric Motors

The following is the list of electric motors installed:—

For initial pumpage of raw sewage	1—7½ h.p. motor.
For lime treatment—	
Lime crusher	1—5 h.p. motor.
Effluent pumps	2—1 h.p. motor.
Feeding and agitation	2—1 h.p. motor.
For electrolytic cell—	
Paddles	1—3 h.p. motor.
Electrolysis	1—5 k.w. motor generator set.
For handling grit and sludge—	
Grit pump	1—2 h.p. motor.
Sludge pump	1—1 h.p. motor.

Of the four 1-h.p. motors listed under lime treatment only two would be in service at a time.

Description of the Process

The process is essentially one of fine screening, followed by lime precipitation, agitation, electrolysis and sedimentation.

The screening through ¼-in circular openings removes from the crude sewage solid particles of larger size than these openings.

The addition of the lime is claimed by the owner of the electrolytic process to be essential to that phase of the treatment of the sewage, but it should be borne in mind that chemical precipitation of sewage is one of the oldest processes known to the art and produces a very considerable removal of suspended solids.

The electrolytic action liberates nascent oxygen and hydrogen by the passage of the electric current through sewage rendered alkaline by the addition of lime. The agitation, in addition to its well-known effect in inducing precipitation, brings the sewage into intimate contact with the products of electrolysis. Chemical reaction is thereby stimulated while the gases are still in the nascent state and before they have an opportunity to escape. The paddles undoubtedly serve also to mechanically clear the plates and prevent polarization.

Positive Alkalinity

In normal operation the lime suspension is added to the sewage immediately before entering the electrolytic cell in order to insure positive alkalinity, a condition considered necessary for electrolysis without attack of the electrodes. There is a gradual deposit of calcium carbonate on the plates, which it is claimed can be remedied by temporarily shifting the point of applicaton of the lime to the outlet flume leading from the electrolytic cell. The sewage under such conditions is said to rapidly remove the coating from the plates, permitting normal operation to be resumed in 15 or 20 minutes. A heavy deposit on the plates is indicated by a marked increase in the power required to drive the paddles. No considerable increase was noted during the period of the test.

Some polarization of the plates occurs from time to time, but this is overcome by a reversal of the polarity, which quickly decreases the necessary voltage and increases the current.

For satisfactory operation it is said that the cell effluent should contain not less than 30 parts per million of excess alkalinity. During the period of the test this content was always exceeded.

As the sewage reaches the observation flume after passage through the electrolytic cell it contains the lime and the suspended solids. The subsequent sedimentation is to permit the deposition of these materials so as to clarify the effluent and separate the sludge for treatment.

Condition of Test

The plant had been closed since about October 15th, and intermittent operation was again resumed on December 2nd, only two days prior to starting the 8-hour test.

During the test the plant was operated by the company in order that there might be no division of authority and to controvert possible criticism regarding inefficient operation. The department's representatives observed the operation of the plant, made tests on power consumption, quantity of lime used, flow of sewage, and took samples of the sewage, etc.

Prior to undertaking the test all by-pass connections were closed and sealed, electric meters and water meters were read, and various measurements were made of the dimensions of the units.

During the 8-hour test electric and weir readings were taken at intervals of 15 minutes and at intervals of 30 minutes during the 24-hour test. Samples of the sewage, proportional to the flow, were collected every 30 minutes during the 8-hour test and every hour during the 24-hour test. These were mixed to form composites for chemical analysis for each test run. Settleability and alkalinity samples were collected every four hours, and putrescibility, dissolved oxygen and bacteriological samples were collected every 8 hours. Lime samples were collected at irregular intervals, averaging probably two hours, and thoroughly mixed, forming a single sample for analysis.

The Standard Methods of Analysis of the American Public Health Association were followed at the laboratory.

The flow of sewage was determined by weir readings taken every 30 minutes during the tests and varied from a minimum of 309,000 gals., which occurred at 2.30 a.m., to a maximum of 816,000 gals., which occurred at 11.30 a.m. The average flow during the 24-hour test was at the rate of 460,000 gals. per day, or slightly less than one-half the rated capacity of the plant.

During the 8-hour test the polarity of the electrolytic cell was changed at 3.23 p.m. in order to decrease the effects of polarization. Immediately after such change the voltage was found to be 40 and the amperage 55. During the 24-hour test a similar change was made on several occasions, but the exact hours were not noted.

At 4.20 on December 6th a portable voltmeter was applied to the various electrodes to determine whether the total voltage at that time was evenly distributed throughout the electrolytic cell. The results at the outlet end were as follows:—

Upper bank..	2.8	2.7	2.85	2.7	2.75	2.9	2.95	2.9	3.1	3.0	3.75
Lower bank..	3.0	2.7	2.55	2.65	3.0	2.9	2.8	2.75	3.4	2.8	3.45

Immediately after the completion of the test the switchboard ammeter was compared with a portable millivoltmeter with external shunt. The two were found to agree within 2 or 3 per cent.

Summary of Results of Tests

The following is a summary of the results of the tests:—

Power Consumption.	8-hr. test.	24-hr. test.
Lights and electric heaters..	11 k.w. hrs.	47 k.w. hrs.
Pump motor	30 k.w. hrs.	90 k.w. hrs.
All other power	50 k.w. hrs.	130 k.w. hrs.
Total	91 k.w. hrs.	267 k.w. hrs.
Total water consumption*..	66 cu. ft.	166 cu. ft.
Quantity of lime.....	....	1,712 lbs.
CaO content	....	61.52%
Average voltage for electrolysis	56.3	57.5
Average current for electrolysis, amperes	37.8	33.8
Average wattage for electrolysis	2,125	1,944
Average wattage for paddles	1,388	1,355
Sewage flow in gals. per 24 hrs.	482,700	460,000
Average sewage flow in gals. per hour	20,110	19,190
Electrolytic hydrogen liberated in grams per hour..	31.04	27.82
Electrolytic oxygen liberated in grams per hour.....	247.73	222.03
Ratio of electrolytic hydrogen to sewage by weight....	0.4 p.p.m.	0.4 p.p.m.
Ratio of electrolytic oxygen to sewage by weight...	3.2 p.p.m.	3.0 p.p.m.

Oxygen consumed	53	52	44	44

Raw sewage samples were collected from the discharge pipe of the pump after sewage had passed the bar screen. Screened sewage samples were collected after the sewage had passed the bar screen, the pump, the plate screen and the grit chamber. The samples of the cell effluent were taken from the observation flume. This sewage had passed the bar screen, the pump, the plate screen, the grit chamber and the electrolytic cell, and had also received the lime treatment.

Putrescibility of Sludge from Resettling Basins

	100% sludge	75% sludge, 25% river water	50% sludge, 50% river water	25% sludge, 75% river water	100% river water
Standard quantity methylene blue solution	3 hrs.	3 hrs.	3 hrs.	3 hrs.	14 days
Three times standard quantity methylene blue solution	3 days	14 days	1 day	3 days	14 days

In the above table the entries signify the period during which the samples retained a blue color excepting in cases where the entry reads 14 days, which signifies that the color was still present when the samples were thrown away at the end of the 14-day period.

It was feared the bleaching properties of the lime would have a marked effect on the methylene blue solution added to samples of sludge mixed with varying proportions of the river water. Accordingly, the standard quantity of methylene blue solution was added to one set of samples and three times this standard quantity to the check set, including the control samples. It will be noted that the samples of 100% river water were stable for two weeks in both cases, but in the other samples, containing varying proportions of sludge and river water, the lime apparently had a perceptible effect upon the methylene blue. The samples containing the greater proportion of methylene blue retained the color for longer periods, although the period of retention of color was not proportional to the percentage of river water, tending to throw some doubt upon the accuracy of this determination.

The appearance of the raw sewage was typical of fresh dilute sanitary sewage from an American municipality except at times when brewery wastes are present.

The effluent from the electrolytic cell had a brownish cast, contained a flocculent precipitate, and evidenced tendency to form a floating froth in the observation flume and inlet end of the settling basin. The flocculent precipitate settled rapidly, leaving a clear, greenish-tinged supernatent liquid, excepting when large volumes of brewery wastes were passing through the plant, when the effluent from the basin was clear amber color and contained some suspended matter.

There was no opportunity during the test to determine the feasibility of drying sludge from the settling basin upon the sand beds.

At the end of the 24-hour test the cover on the effluent end of the electrolytic cell was removed and the electrolyte drawn down a short distance below the top of the plates. After removal of the coating these plates, as far as could be seen, were bright and in good condition. The coating, which was removed easily by rubbing with the fingers, was found on analysis to contain 1.73% of iron.

There was no evidence during the test that under operating conditions there is a rapid deterioration of the plates to form a chemical coagulant, which was purposely intended in the early processes for the electric treatment of sewage.

Life of Electrolytic Cell

The company states that the cell under test at Easton had not received any repairs during the summer, and, in fact, the cell cover had not been removed prior to the conclusion of the 24-hour test when it was opened at request of the department representatives in order to observe the condition of the plates.

Records of electric current consumed during the past summer (May to October, inclusive) were obtained from the monthly statements of the local electric company. It was found that the current consumed by the pump would have been sufficient for approximately 18 days' continuous operation and current recorded by the meter supplying circuits for the lime-feeding and mixing devices, the solution pump, electrolytic cell and revolving paddles would have been sufficient for approximately 16 days' continuous operation. These periods are obtained by using the current consumption during the 24-hour test as a basis. The higher figure for the pump is probably due to the fact that the flow of sewage was greater on some days than during the 24-hour test, while the current required for the lime-feed and the cell did not vary uniformly with the flow of sewage.

The company states that the cell remained filled with sewage during periods when it was not operated.

Freedom from Nuisance

During the department's test the entire apparatus was free from objectionable odors. Inquiry was made at houses in the vicinity and it was found that the residents quite generally had no cause for complaint.

There is little reason to anticipate nuisance conditions from the screens, cell or settling basins when handling fresh sewage for there would normally be dissolved oxygen present throughout the process. Freedom from nuisance, however, cannot be predicted with any degree of certainty in a large municipal plant which must necessarily contain sludge beds or sludge presses for dewatering the sludge. In fact, it is altogether probable that disposal of the sludge would at times be attended by offensive odors.

Difficult to Predict Costs

It is difficult to predict, with a satisfactory degree of accuracy, the cost of operating a large unit by comparison with data collected through operation of a single small unit. However, in the absence of complete information reliance must be placed upon such data as are available and reasonable factors applied to meet expected conditions in the larger plant. The following figures regarding cost of operating the plant at Easton are therefore given as a rough indication of what might be expected, but apply more particularly to a plant of a similar size operating under the same conditions—namely, pumping of sewage and the addition of lime at a rate stated by the owner of the patent as being greatly in excess of that necessary to secure satisfactory results:—

Cost of Operation

Without Pumpage—	
Hydrated lime, 1,712 lbs. at $6.75 per ton	$ 5.78
Water for mixing lime, 20 cu. ft. at $0.003 per cu. ft.	.06
Electric power, 130.6 k.w.h. at $0.0226	2.95
Electric lights, 6¼ k.w.h. at $0.0805	.50
Heating	1.25
Labor and superintendence	15.00
Electrode renewals, company's estimate	1.00
Maintenance and repair	1.50
Total	$28.04
Add for Pumpage—	
Electric power, 88.3 k.w.h. at $0.0226	2.00
Water, 120 cu. ft. at $0.003 per cu. ft.	.36
Total	$30.40
Equivalent cost per 1,000,000 gals.	66.00

These figures are on the basis of pumping and treating 460,600 gals. excluding allowance for interest and sinking fund charges and cost of sludge pumping, treatment and disposal. The costs of hydrated lime, water and electric current are those which the department understands obtain at Easton. The figure for labor and superintendence is based upon employment of a superintendent at $1,650 a year who should be able to make necessary bacteriological and chemical tests and who is familiar with the theory of operation of the

(Continued on page 395.)

GOVERNMENT CONTROL OF G.T.R.

THE Grand Trunk Railway System of Canada, with all its lines in and out of the Dominion, including the Grand Trunk Pacific, is to pass into the possession and control of the Dominion Government. The bargain has been made with the government by Sir Alfred Smithers, representing the stockholders of the Grand Trunk. It will have to be ratified by Parliament and by the stockholders of the Grand Trunk.

The stock of the company is to be acquired by the government. The payment will not be in cash, but by an exchange of securities. The holders of the preferred and common stock will transfer their shares to the government, and will receive in exchange therefor shares which will have no voting power, but will earn four per cent. guaranteed by the government. As the preferred and common shares of the company are now considerably below par, their value is to be determined by a board of arbitration and the agreement provides for the appointment of such a board.

The debentures will be assumed by the government. They amount to £31,926,125. The guaranteed stock, amounting to £12,500,000, will be treated as debenture stock, and the payment of the 4 per cent. dividend will be guaranteed by the government.

The holders of debentures and guaranteed stock are to surrender all voting powers.

The other stock of the company falls into four classes, namely, first preference, second preference, third preference and common; the total par value of these four stocks is £37,073,492.

As soon as the bargain has been ratified, the road will be turned over to a committee of management. Two members of the committee will be named by the government and two by the company, and the four will select a fifth member. This committee will operate the road during the arbitration, and will operate it in close connection with the Canadian National Railway System. After the arbitration has been completed and the stock has been transferred to the government, the committee of management will be discharged and the Grand Trunk lines will become a part of the Canadian National Railway System.

In estimating the value of the stock the arbitrators are to refer to the fixed charges and other liabilities of the Grand Trunk and will take into consideration all the liabilities of the Grand Trunk on account of the Grand Trunk Pacific.

Hon. Arthur Meighen, Minister of the Interior, has introduced into Parliament a resolution ratifying the agreement with the G.T.R. It will be debated at length during the present session.

PROPOSED SCHEDULE OF CIVIC SALARIES AT BALTIMORE

THE Baltimore chapter of the American Association of Engineers presented to the Board of Estimates of the city of Baltimore, under date of September 27th, a report of the compensation committee of that chapter on salaries of engineer employees of the city, with the request that the board analyze the situation and take such action as seems advisable.

The schedule recommended covers more than 60 grades of engineer employees of the city. It recommends an increase for the chief engineer of at least $2,500 to bring his salary up to a minimum of $10,000 per annum, with a maximum of $15,000. Some of the other recommendations are tabulated below:—

Present Title	Present Annual Salary	Annual Salary Recommended by Committee Minimum	Maximum
Highways Engineer, Water Engineer, Harbor Engineer, Chief Engineer Paving Commission and Inspector of Buildings	$4,000	$5,000	$7,500
Division Engineer of Sewers	3,300	3,600	5,000
Principal Assistant Engineer Water Department	3,000	3,600	5,000
Mechanical Engineer Water Department	2,700	3,600	5,000
Assistant Engineer Water Department	2,200	2,700	3,300
Assistant Engineer of Bridges and Improvements Highway Dept.	2,000	2,700	3,300
Designing Engineer Water Department	1,800	2,700	3,300
Assistant Engineer, Grade AA, Water Department	.....	2,400	3,000
Office Engineer Paving Commission	2,000	2,400	3,000
Field Engineer Highways Department	1,500	2,400	3,000
Draftsmen all Departments	1,500 max.	1,500	2,100
Instrumentmen all Departments.	1,200	1,500	2,100
Rodmen all Departments	1,020	1,200	1,500
Tracers all Departments	840 max.	1,080	1,200
Chainmen all Departments	900 max.	1,080	1,200

ASSOCIATION OF C. B. & C. I. CONSTITUTION

THERE should be no delay in adopting the constitution that has been drawn up for the Association of Canadian Building and Construction Industries by its president, J. P. Anglin, of Montreal. The association has been badly handicapped in its work this year by the lack of such an instrument. Both Mr. Clarson, the former general secretary, and Mr. Reilly, the present acting general secretary, have been placed in the undesirable position of "passing the hat" instead of being able to solicit membership upon a clean-cut basis in a definite organization.

The Association of Canadian Building and Construction Industries began well at the splendid general conference held last November in Ottawa, but since then it has been largely a mythical and shadowy form, lacking definiteness and concrete shape. The constitution which Mr. Anglin proposes, if formally adopted by the members of the national council, to whom the delegates of the last convention gave the right to prepare and adopt such a constitution, the whole status of the association will be materially and beneficially changed.

By the adoption of this constitution, the association will become a living entity. There will be a definite *modus operandi* and fees will be collected upon a business-like basis. The relations of the association to local bodies will be clearly defined, and through the large representation of local bodies in the membership of both the association at large and of the national council, the various builders' exchanges through the country will, to a large extent, govern the affairs of the national association. In fact, with the strengthening and growth of the local associations that will result from the co-operation of the national association, the representation of local associations will so grow that the national association will largely become a national parliament of representatives of local associations.

These representatives, who will in the main be representatives of a large number of comparatively small firms throughout the country, will be aided in their deliberations, and their actions will be given additional weight and prestige, by the presence in these national parliaments of the direct members, who will in the main be representatives of the big business interests of the country.

ARBITRATION vs. INVESTIGATION

AN interesting article in the constitution that is being considered by the national council of the Association of Canadian Building and Construction Industries, but one which is not likely to prove of very tangible benefit to members of the association, is the article providing that the executive committee be empowered to appoint arbitrators to hear and decide controversies, disputes or misunderstandings relating to any commercial matters or practice as between members of the association, which may be voluntarily submitted by the parties in dispute.

We venture to predict that the executive committee will not be worked overtime with the appointment of such boards of arbitration. A board appointed in such a manner would be a tribunal or investigating committee, but not a board of arbitration. The members who make use of this clause will be practically referring their disputes to the executive committee, or at least, practically speaking, to a sub-committee whom the executive committee may appoint to examine into and settle the dispute.

There is only one way in which a real board of arbitration can be formed, and that is the generally recognized method of having one party to the dispute appoint one member and the other party to the dispute appoint the second member, and then to have those two members select a third.

It is possible, however, that the arbitrations which the framers of this constitution had in mind, were not so much industrial or financial disputes as trade customs or practices. Just how far the executive committee or national council of the association should go, either directly or through appointed committees, in legislating trade practices, is a debatable point and one which will no doubt be the subject of much discussion in years to come.

There is no question but that the association could be of material benefit to the building and construction industry as a whole by enforcing certain desirable customs and by eliminating a number of undesirable practices; however, activities along these lines are very likely to be challenged by individual members, and might be misunderstood by the public as savoring too much of a "gentlemen's agreement" or "contracting ring." The arbitration article in the association's constitution will prove to be either a dead letter or else somewhat of a "joker," pregnant with possibilities.

C. M. I. COMMENT ON CLASSIFICATION

"COMMENT on the new Civil Service classification and schedule of compensation has already appeared in several recent issues of the 'Bulletin,'" says the October issue of the "Canadian Mining Institute's Bulletin." "The proposals embody the recommendations made to the government by Arthur Young & Co., of Chicago, Toronto and New York, and they have called forth serious objections from many of the engineers in the civil service.

"The classification proposed is so unscientific and cumbrous that it is an almost impossible task to make a comparative analysis of the salary schedule as it applies to technical men in the different government departments. So far as is possible, however, such an analysis has now been made by Arthur S. Tuttle, chairman of the U.S. Engineering Council's committee on classification and compensation of engineers.

"Since this committee has made a special study of the subject, Mr. Tuttle's report carries weight. It raises many of the same criticisms which have already been voiced by individual engineers."

OPERATING RESULTS OF "DIRECT OXIDATION"

(Continued from page 393)

process and upon employment of an operator on each 8-hour shift at a salary of $1,200 a year.

If we assume that the plant could be operated continuously at a normal rating (1,000,000 gals. a day) the unit costs would be materially reduced and would probably be approximately as follows:—

Without Pumpage—	
Hydrated lime, 3,720 lbs. at $6.75 a ton	$12.56
Water, 20 cu. ft. at $0.003 per cu. ft.	.06
Electric power, 185.5 k.w.h. at $0.0226	4.19
Electric lights, 6¼ k.w.h. at $0.0805	.50
Heating	1.25
Labor and superintendence	15.00
Electrode renewals	1.00
Maintenance and repairs	1.50
	$36.06
Add for Pumpage—	
Electric power, 117.7 k.w.h. at $0.0226	$ 2.66
Water, 120 cu. ft. at $0.003	.36
Total	$39.08

These figures are exclusive of allowance for interest and sinking fund charges and cost of sludge disposal. It will be noted that the lime has been increased proportionately to the flow as this quantity was added during the test. Should it later appear that the quantity of lime can be reduced without deterioration of the effluent there would be a corresponding reduction in cost of treatment. It is probable that the cost of sludge, pumping, treatment and disposal will be in the neighborhood of $7.50 per 1,000,000 gals.

Conclusions of Engineering Division

Consideration of the performance of the plant as operated by the owners and as observed by the members of the Engineering Division of the department on December 4 and 6, 1918, lead to the following conclusions:—

1. The combined action upon the sewage of the fine screen, lime treatment and the electrolytic cell render the sewage in such a condition that after sedimentation in properly designed tanks, the effluent can be discharged into a stream, affording a reasonable dilution of relatively clean water, without danger of creating a nuisance. It is, of course, assumed that the effluent will be discharged through properly designed outlet so as to cause dispersion in the stream.

2. The fine screen, lime treatment and electrolytic cell have a destructive action on bacteria of the colon group. If, however, the use of the receiving body of water demands a high degree of bacterial removal in sewage effluents discharged therein, it would be on the side of safety to provide for disinfection of the cell effluent.

3. Assuming fresh domestic sewage, proper design, operation and maintenance of the various devices, the treatment of sewage by the above described processes should be free from objectionable odors, with the possible exception of the removal and disposal of the screenings and the sludge from the final settling basins.

4. Similar screenings are being successfully disposed of elsewhere by incineration or burial and the sludge from the final settling basins should be susceptible of dewatering by presses such as are used in sewage treatment works, including the lime precipitation method.

5. The process should be extended by installation of some adequate method for treatment of sludge removed from the settling basins as discharge of this sludge with the cell effluent is not permissible.

6. The cost of installation of a sewage treatment works, including the above processes should not be excessive, but the cost of operation would appear to be higher than for other methods of sewage treatment in general use to produe an equal quantity of effluent.

Each proposed installation should be examined by com-

(Concluded on page 396)

PERSONALS

J. M. DIVEN, secretary of the American Water Works Association, who is planning the details of the next annual convention, which will be held in Montreal, Que., has resigned as superintendent of the bureau of water of Troy, N.Y., and will devote his entire time hereafter to the affairs of the association. Mr. Diven's headquarters will be in New York City, the association having secured rooms at 153 West 71st St. Mr. Diven's connection with the water works industry has been of long standing. In November, 1873, he was appointed as an assistant in the office of the Elmira Water Works Co., in Elmira, N.Y., and two years later became secretary-treasurer of the company. At first he was in charge of the office, but later he gradually assumed the outside work, and in 1886 he was appointed superintendent of the company. In January, 1905, Mr. Diven resigned at Elmira in order to go to Charleston, S.C., as superintendent of the Charleston Light & Water Co., which position he relinquished in 1912, when he was appointed superintendent at Troy. Mr. Diven was first appointed secretary of the American Water Works Association in 1889, and he served in that capacity until 1891, when he was elected president. The following year he became secretary-treasurer, but later those two offices were separated and since 1902 he has been secretary of the association.

D. W. MUNN, of Montreal, has been appointed professor of civil engineering at the Royal Military College, Kingston, Ont.

LEONARD DUNAWAY, who has been in the British navy for the past four years, has been appointed superintendent of the Vermilion, Alta., power plant.

M. J. BUTLER, managing director of Armstrong & Whitworth of Canada, Ltd., of Montreal, has resigned and is now living in Oakville, Ont. Mr. Butler was deputy minister and chief engineer of the Department of Railways and Canals from 1905 to 1910, when he resigned to become second vice-president and general manager of the Dominion Iron & Steel Co. and the Dominion Coal Co. He left the Dominion companies in 1912 in order to organize a Canadian branch for the well-known English firm, Sir W. G. Armstrong, Whitworth & Co., Ltd. Mr. Butler is a Companion of the Order of St. Michael and St. George, and is also a doctor of laws. He was called to the Illinois bar in 1897, nineteen years after he commenced practice as an engineer and Dominion Land Surveyor.

OBITUARY

FRANK J. LYMAN, managing director of the Lyman Tube & Supply Co., Ltd., Montreal, died suddenly two weeks ago at the age of 42. He was the founder of the business, which was the successor to the railway department of John Millen & Son, Ltd., Montreal, which department he managed for 10 years prior to the establishment of the Lyman Tube & Supply Co., Ltd.

OPERATING RESULTS OF "DIRECT OXIDATION"

(Continued from page 395)

parison with other methods of sewage treatment to determine if savings in installation cost would be sufficient to counterbalance the increased maintenance and operation charges.

If it should be determined that the proportion of lime could be materially reduced without deterioration in the quality of effluent there would be a proportionate reduction in operating costs.

7. To permit continuous operation of a works including these processes, electrolytic cells and other equipment must be in duplicate. It is undoubtedly necessary to replace plates in the electrolytic cell from time to time and accordingly a type of cell should be adopted which admits of such renewals in place and at a minimum cost for labor.

8. The short observations of the combination of fine screening, lime treatment, electrolytic cells and final settlement appear to justify an extended test by this department should the opportunity be offered. Such tests should include study of results secured with lime additions reduced to the proportion the owner of the patent claims as the actual needs of the process and should also include study of various methods of treatment and disposal of the sludge from the resettling basins.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Barrie, Ont.—Sidewalks may be constructed on Victoria St., between Sanford and Innisfil Streets, on the south side of Sophia St., on the west side of Bayfield St., and on the north side of Ross St., from Small St. to Kidd's Creek.

Barrie, Ont.—The town council instructed K. S. Macdonell, town engineer, to secure estimates on a pavement for Dunlop and Elizabeth Streets.

Batiscan, Que.—The provincial government has decided to erect a steel bridge over the Batiscan river.

Bedford Tp., Que.—The township council decided to carry out a programme of road improvement. Application will be made to the Provincial Road Department for $20,000 under the Good Roads Act, and the roads will be built as early as possible next year.

Calgary, Alta.—City council decided to have Tenth Ave., from Eighth St. W. to Fourteenth St. W., graded, at a cost of $2,366. City clerk, J. M. Miller.

Chatham, Ont.—Tenders will be received by W. M. Abraham, R.R. No. 1, Chatham, Ont., up till noon on Saturday, October 18, for the construction of about 18,000 square feet of sidewalk on Grand Ave. and Taylor Ave., near Chatham. Plans and specifications may be seen at the office of W. G. McGeorge, C.E., Chatham.

Dundas, Ont.—Ratepayers will vote on a by-law to provide $3,500 for rebuilding Head St. bridge. Engineer, J. W. Tyrrell, Hamilton.

Hamilton, Ont.—The city council intends to construct a pipe sewer on Bay St., from Macaulay St. to Burlington St. S. H. Kent, city clerk.

L'Assomption, Que.—Tenders will be received up to 10 o'clock a.m. of October 20th, 1919, by Jos. E. Duhamel, secretary-treasurer, L'Assomption, Que., for the erection of a bridge. One price must be for the superstructure in steel and another price for all the other work in constructing the bridge. For all further particulars, address the secretary-treasurer.

Lindsay, Ont.—Town council instructed the board of works to construct several granolithic walks. Clerk, Duncan Ray.

London, Ont.—A by-law will be submitted to the ratepayers in January, authorizing an expenditure of $50,000 for a new bridge on Ridout St.

London, Ont.—Tenders, addressed to the "Chairman and Members, No. 2 Committee," will be received at the office of the city clerk up to 3 p.m. on Monday, October 27th, 1919, for the supply of one 1,200 U.S. gallon capacity motor-driven street flusher, complete. Specifications, etc., may be obtained at the office of H. A. Brazier, city engineer.

London, Ont.—The construction of a new pavement on King St., between Wellington and Richmond Sts., is to be commenced at once. City clerk, S. Baker.

New Westminster, B.C.—The provincial department of railways has decided to construct a footbridge sidewalk as an addition to the railway bridge which spans the Fraser river here. Estimated cost about $13,000 or $14,000.

Norwood, Ont.—It is reported that the Provincial Highways Department, in order to test the qualities of the rock from the Belmont township quarries for road-building, will construct a piece of road between Havelock and Trent River, a distance of about four miles.

FOR SALE—CHEAP

One Buffalo Pitts Road Locomotive

With Six 4-yard Bottom Dump Cars and Two 20-ton Freight Cars.

Return to United States Duty Free. Guaranteed first-class condtion.

L. P. BURNS, LIMITED
364 301 Bank of Hamilton Bldg., Toronto, Canada

20-Year Barrett Specification Roof on Foundry Bldg. of Thos. Davidson Mfg. Co., Ltd., Montreal. Can. Arch.: A. W. Robinson, Montreal; Gen. Con.: A. F. Byers & Co., Montreal; Roofers: Hickey & Aubut, Montreal.

A 20-Year Guaranty Roof protects this Canadian Foundry—

A foundry roof has more than weather to withstand. It must be able to resist the intense heat of the furnaces underneath, and showers of red-hot sparks from above.

When the roof on the foundry building shown above was completed we gave the owners a Surety Bond *guaranteeing* their roof to be free from maintenance expense for *20 years*.

In this case the Surety Bond was hardly necessary, for the Thos. Davidson Mfg. Company, Ltd. knew from experience what service to expect, as the following paragraph from their letter to us shows:

"You will no doubt be interested to know we have insisted on Barrett Specification Roofs on all our plants, as our experience has proved it to be in every way satisfactory."

Not only are Barrett Specification Roofs "in every way satisfactory," but they cost less per-year-of-service than any other type of permanent roof, and they take the base rate of fire insurance.

20-Year Guaranty

So sure are we of the service Barrett Specification Roofs will give *under the most severe conditions*, that we are prepared to *guarantee them for 20 years*, in all towns of 25,000 or over, and in smaller places where our Inspection Service is available provided they are 50 squares or more in area. The guaranty costs you nothing. We merely require that our Specification dated May 1, 1916, shall be strictly followed and that we have an opportunity to send inspectors to watch the job during construction. The guaranty is a Surety Bond issued by a well-known fidelity and guaranty company.

Copies of The Barrett Specification, with roofing diagrams, mailed free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Shipton Tp., Que.—Township council decided to either repair or rebuild the bridge in No. 75 district.

Simcoe County, Ont.—The Simcoe County Roads Committee let contract to R. Curran and Co., at $12,500, for the paving of Atherley Rd., from the G.T.R. track to Moffatt St., a distance of half a mile. The contract calls for a concrete road, 20 ft. wide, with storm sewers and ditches.

Smith's Falls, Ont.—The Provincial Highways Department has approved of the designation made by the Lanark county council of a county provincial highway, estimated to cost over $700,000.

St. Clements, B.C.—Tenders addressed to Duncan C. Scott, deputy superintendent-general on Indian affairs, Department of Indian Affairs, Ottawa, and endorsed "Tenders for the construction of a wooden bridge over the Brokenhead river, river lot 6, Brokenhead Indian Reserve, municipality of St. Clements, B.C.," will be received up to noon, November 19th, 1919. Plans and specifications may be seen at the post office at Selkirk, Man., and at the office of Inspector Bunn, Winnipeg, Man., also upon application to the Department of Indian Affairs, Ottawa, Ont.

St. John, N.B.—City council is considering repairs to City Rd. sidewalk, between Gilbert's Lane and Wall St., at an estimated cost of $7,000. City engineer, G. N. Hatfield.

St. John, N.B.—A parkway through King St. E. is proposed by the civic authorities. A sketch of the street shows a parkway 20 ft. in width extending through the centre, with paved roadways 30 ft. in width on either side, and protected by curbing.

St. Louis de Gonzague, Que.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, October 29th, 1919, for the construction of two concrete bridge abutments on River St. Louis, at St. Louis de Gonzague, Beauharnois County, Que. Plans may be seen and specification obtained at the Department of Public Works, Ottawa, at the offices of the district engineers, Shaughnessy Building, Montreal, Que., post office building, Quebec, Que., and at the post office, St. Louis de Gonzague, Que.

St. Thomas, Ont.—A special committee has been appointed by the city council to confer with the Michigan Central Ry. officials with the object of constructing pedestrian subways at street crossings along the railway tracks.

Toronto, Ont.—City council intends to construct a 5-ft. cement concrete sidewalk on Adams Ave., s.s., between Shaw St. and Ossington Ave., at an estimated cost of $1,680.

Toronto, Ont.—City council intends to construct asphalt pavements on parts of Avoca Ave., Carlton St., Dufferin St., Gilmour Ave., Logan Ave., Maria St., Morley Ave., Normandy Boulevard, Park Rd., Rhodes Ave., St. Clemens Ave., at an estimated cost of $172,914; brick block pavements on Rhodes Ave., lane 1st south of Humberside Ave., Morley Ave., Normandy Blvd., estimated cost, $54,394; brick pavements on Park Rd., at estimated cost, $17,439; concrete sidewalks on Durie St. and Pine Ave., estimated cost, $6,858; and concrete curbings on Maria St. and Glendonwynne Rd., estimated to cost $587.

Toronto, Ont.—City council intends to extend Stacy St., from Coxwell Ave. to Rhodes Ave., at an estimated cost of $5,550; also to widen part of Day Ave. at a cost of $2,600.

Winnipeg, Man.—A by-law for the proposed new bridge across Assiniboine River at Maryland will be submitted to the ratepayers on November 28th.

WATER, SEWAGE AND REFUSE

Blenheim Tp., Ont.—Tenders will be received by Hugh Allan, township clerk, Drumbo, Ont., up till noon, October 18th, for the furnishing of 57 ft. of 6-in. tile, 425 ft. of 8-in., 3,275 ft. of 12-in., 1,800 ft. of 14-in. and 281 ft. of 16-in. tile; also for the work necessary in the construction of the Costin drain. Plans and specifications may be seen at the clerk's office.

Courtright, Ont.—The by-law to raise $12,000 for the construction of a waterworks system was defeated by the ratepayers.

Hamilton, Ont.—Dr. James Roberts, M.O.H., will shortly ask the city to provide additional sanitary equipment for filtering city water.

Kincardine, Ont.—Town council decided to install a chlorination plant at the power-house. Clerk, J. H. Scougall.

New Liskeard, Ont.—The town council has authorized its waterworks committee to have the deep well now in use repaired and also to obtain estimates for motors and pumps to link up the artesian well. Clerk, J. I. Dixon.

North Grimsby Tp., Ont.—Tenders will be received at the office of J. W. Tyrrell, township engineer, 7 Hughson St. S., Hamilton, Ont., where plans and specifications may be seen up to 12 o'clock noon, October 18th, for the work of cleaning out and repairing what is known as the Ingram drain, through lots M, D and C, and the adjoining roads in the East Gore of the township of North Grimsby.

Ottawa, Ont.—City council intends to construct tarvia macadam pavements on Stewart St., from Waller St. to Chapel St., estimated cost, $26,191, and on Hastey Ave., from Laurier Ave. to Osgoode St., cost, $7,332.10. Also an asphalt pavement on Besserer St., from Charlotte St. to Wurtemburg St., cost, $5,040.20. City clerk, Norman H. H. Lett.

Ottawa, Ont.—City council intends to construct 9-inch tile pipe sewers in Warren Ave., from Wellington St. to Byron St., estimated cost, $2,098.02; Granville Ave., from Wellington St. to the Ottawa Electric Ry., cost, $2,317.25; Hampton Ave., from Wellington St. to the Ottawa Electric Ry., cost, $2,169.97; Harmer Ave., from Wellington St. to Byron St., cost, $2,330.07; Cooper St., from the west limit of lot 54, Cooper St., to a point 80 ft. west of Elgin St., cost, $978.15; Grove St., from Leonard Ave. to Seneca St., cost, $1,681.70, and Beechwood Ave., from Putman Ave. to a point 65 ft. north, cost, $303.55. City clerk, N. H. H. Lett.

Peterboro', Ont.—City council decided to proceed at once with negotiations for the purchase of a site for the proposed sewage disposal plant. City engineer, R. H. Parsons.

Peterborough, Ont.—City council is considering the construction of sewers on Bethune and McDonnel Streets. City engineer, R. H. Parsons.

Regina, Sask.—The city council referred to the city commissioners a petition for sewer and water on Winnipeg St., between Fourth and Eighth Avenues. City engineer, D. A. R. McCannel.

Toronto, Ont.—The date for receiving tenders for the construction of sewers on College St., Beatrice St. to Palmerston Ave.; College St., Palmerston Ave. to Sapdina Ave.; Bowmore Rd., north limit, Plan 522-E, to Wrenson Rd., has been extended from noon on Tuesday, October 14th, 1919, to noon, Tuesday, October 28th, 1919.

Welland, Ont.—City council has requested the Fire, Water and Light Committee to have a Hydro pump installed as an auxiliary in the waterworks pump house.

West Oxford Tp., Ont.—Tenders for the construction of the service drain, consisting of 3,760 ft. of tile drain, and also for the construction of the Cedar St. drain, consisting of 1,512 ft. of tile drain will be received by F. J. Curry, clerk, R.R. No. 1, Woodstock, Ont., until noon, October 18th, 1919. Plans and specifications may be seen at the office of the township clerk.

York Tp., Ont.—York township has taken up the problem of providing a sewer system for Todmorden and the north Danforth district. At a recent meeting of the township council Engineer R. O. Wynne-Roberts presented a report on the engineering aspect of the scheme, and suggested that an immediate decision be reached on the question of taking care of sewage and storm water in one system or in two systems, and also that a district be mapped out. It was decided to adopt the separate system idea, but the storm sewers will not be installed for some time. The engineer was authorized to take up the question of a site for the disposal plant.

Burlington Steel Co., Ltd.
Hamilton, Canada

STEEL BARS
For
Concrete Reinforcing

THE MOST IMPORTANT FACTOR IN CONCRETE REINFORCEMENT IS THE TENSILE STRENGTH AND ELASTIC LIMIT OF THE REINFORCING BAR.

OTHER THINGS BEING EQUAL, STEEL HAVING THE HIGHEST ELASTIC LIMIT, OR YIELD POINT, WILL BE THE MOST SATISFACTORY FOR REINFORCEMENT. WHEN UNDER STRAIN, AS SOON AS THE ELASTIC LIMIT OF ANY REINFORCING BAR IS REACHED, THE METAL STRETCHES RAPIDLY DECREASING IN SECTION, DRAWING LOOSE FROM THE CONCRETE AND DESTROYING THE MONOLITHIC BOND EXISTING BEFORE THIS POINT IS REACHED THEREFORE, THE SAFETY OF THE ENTIRE CONSTRUCTION IS IN DIRECT PROPORTION TO THE ELASTIC LIMIT OF THE STEEL USED.

THE ELASTIC LIMIT OF RAIL CARBON STEEL IS 50,000 TO 60,000 POUNDS PER SQUARE INCH, EITHER TWISTED OR PLAIN, AS COMPARED WITH AN ELASTIC LIMIT OF 25,000 TO 30,000 POUNDS IN SOFT STEEL.

THAT'S WHY RAIL CARBON STEEL, WITH ITS 80,000 POUNDS MINIMUM TENSILE STRENGTH, IS RECOMMENDED AS BEING FAR SUPERIOR FOR ALL KINDS OF REINFORCED CONCRETE WORK.

AT OUR HAMILTON, ONT., WORKS WE BUY SELECT RAILS, AND ROLL THEM INTO RAIL CARBON STEEL REINFORCING BARS IN A PLANT WHICH IS THE EMBODIMENT OF THE LATEST THOUGHT AND PRACTICE.

THESE BARS CAN BE SUPPLIED FROM STOCK IN VARIOUS SIZES, LENGTHS AND SHAPES. WE CAN ALSO ROLL SPECIAL SHAPES AND SIZES TO FIT YOUR PARTICULAR REQUIREMENTS.

Bars bent to shape for Beams, Stirrups, Etc.

PROMPT SHIPMENT

LIGHT, HEAT AND POWER

Portage la Prairie, Man.—Contract for the sub-station of the transmission line to be built here has been awarded by the provincial government to Tremblay, Deniset and Co., of Winnipeg, at $3,357.

Saskatoon, Sask.—City Commissioner C. J. Yorath has recommended that the tender of $149,813 of the Canadian Westinghouse Co., of Hamilton, for the installation of a steam turbine generator and switch-gear, also condenser and equipment at the city power house, be accepted.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, November 3rd, 1919, for the supply and erection in the city power-house at Point du Bois of three 5,000 k.v.a. single-phase step-up transformers, with oil and accessories complete. Specification may be obtained at the office of the City Light and Power Department, 54 King St.

RAILWAYS

Alberni, B.C.—The C.P.R. awarded contract to the Foundation Co. for the building of the extension of their line, from Alberni to Great Central Lake, a distance of 10.2 miles.

Chicoutimi, Que.—In a recent request to the provincial government the residents of Chicoutimi and Lake St. John district asked for a belt railway around the lake, with branches from the Ha Ha Bay road to the Quebec-Saguenay road.

Moose Jaw, Sask.—The C.N.R. has been granted permission by the city to construct a temporary subway on Athabaska St. E., on condition that the company agrees to have the permanent subway completed by the fall of 1920.

Pickering Tp., Ont.—The ratepayers passed the by-law in connection with the construction of the Toronto and Eastern Electric Railway.

Scarboro' Tp., Ont.—The township council decided to submit a by-law to the ratepayers on November 22nd on the building of the Toronto and Eastern Ry. through Scarboro' township. Hydro radial construction to be made, if the by-law carries, will amount to eight or nine miles.

Toronto, Ont.—Active preparations are being made for an early commencement of construction work on the Toronto-Port Credit section of the new Hydro radial line that will form the connecting link with the city, of the Port Credit-St. Catharines line and the Toronto-London line.

Winnipeg, Man.—The Dominion government will start surveying for a railway line to the gold fields in northern Manitoba this fall, according to a statement made by Premier T. C. Norris, who recently returned from Ottawa. The railway will be erected from The Pas to the gold belt, about 73 miles north and will cost approximately $2,000,000.

FACTORIES AND LARGE BUILDINGS

Bassano, Alta.—Tenders will be received by Charles Carnegy, secretary-treasurer, Bassano, up to 5 o'clock p.m. on Saturday, October 18th, 1919, for the various works necessary in the alterations and extensions to the hospital. Plans and specifications may be obtained at the office of the secretary-treasurer or at the office of the architect, Charles Hay, 511 Beveridge Block, Calgary.

Calgary, Alta.—McDougall, Trainor and McNeill, Ltd., have been awarded the contract for the construction of a building for L'Air Liquide Society, at First St. E. and Second Ave. This company is a well-known French concern, which is opening up in this country. The company is also building plants in Winnipeg and Vancouver.

Cobourg, Ont.—The board of trade and town council have been holding conferences with a United States manufacturer who is desirous of establishing a branch factory here. The manufacturer wants the loan of about $75,000 to build a factory, also free site and exemption from taxation. Town clerk, Ben Ewing.

Cobourg, Ont.—The Cross Fertilizer Co., of Sydney, N.S., are looking for a site for the erection of a plant here.

Edmonton, Alta.—The Public Library Board is considering the erection of a new library building. Chairman, Mr. Barclay.

Guelph, Ont.—Card & Gray have decided to erect a new brick two-story building on Woolwich St.

Guelph, Ont.—Contract has been awarded for the masonry work in connection with the construction of the new skating arena to W. E. Taylor.

Guelph, Ont.—The C.P.R. intends to erect a large new freight shed here early next spring.

Halifax, N.S.—A housing company is being incorporated, and will erect fifty houses, contracts for which will be let very shortly.

Hamilton, Ont.—The Canadian Carbonate Co., Ltd., of Montreal, capitalized at $500,000, has purchased a site at the foot of Simcoe St., and will make an immediate expenditure of $100,000 on buildings and equipment. J. R. Colby is general manager.

Hamilton, Ont.—The Firestone Tire and Rubber Co., of Akron, Ohio, will establish their Canadian plant here if the ratepayers of Barton township give their assent to two by-laws which are to be submitted to the electors on November 3rd.

Kincardine, Ont.—The Board of Education requested the council to make a grant of $2,500 for repairs to the High School. It was decided to submit the matter to the ratepayers at the municipal elections.

Levis, Que.—There is some talk here of building a large and modern hotel. The new hostelry would be a six or seven-story structure.

London, Ont.—A movement is on foot for the erection of a $100,000 children's hospital as a war memorial.

London, Ont.—The board of education is considering the question of either enlarging Victoria School and Egerton St. school, or erecting new buildings. Extensions will also be made to Ealing, Colborne St. South and Wortley Rd. schools.

Montreal, Que.—A company has been organized here, to be known as the United Inns of Canada, with a capital of $1,000,000. A Federal charter is being applied for. It is planned to erect inns at points, first through the province of Quebec, and then elsewhere in Canada.

Moose Jaw, Sask.—A movement is on foot for the erection of a $130,000 building for the Great War Veterans' Association. Major McNaughton is convener of the committee in charge of the scheme.

New Liskeard, Ont.—The construction of a large pulp and paper mill is expected to begin next year at the north end of Lake Timiskaming. The M. J. O'Brien, Ltd. a $20,000,000 corporation, which controls the O'Brien mine at Cobalt and the Miller Lake-O'Brien mine at Gowganda, as well as other large interests, is involved in the enterprise.

New Westminster, B.C.—School board is considering the erection of a technical school.

Oshawa, Ont.—Contract for the erection of four additional rooms to Mary St. school was awarded by the Board of Education to Mr. Davidson, of Smith's Falls, at $30,000, exclusive of plumbing and heating.

Oshawa, Ont.—The board of education asked the town council for $35,000 to cover the cost of building an addition to Mary St. school.

Ottawa, Ont.—Controller F. Plant has recommended the enlargement of the market and the building of a cold storage plant, etc.

Ottawa, Ont.—The city council have approved the plans of the new civic hospital committee and have agreed to the

appointment of Stevens and Lee, of Boston and Toronto, as architects for the new hospital, which is expected to cost about $1,500,000. The firm are to receive 7 per cent. commission. It is expected that a local architect will be appointed by Stevens and Lee, and paid by them to supervise the building. While several sites are under consideration, it is almost certain that the site upon which the General Protestant Hospital now stands will be chosen and additional land secured adjacent thereto.

Peterboro' Ont.—A permit has been issued to the Canadian Chicle Co. for alterations to the Lundy Shovel and Tool building which they have taken over. Cost, $7,000.

Peterboro', Ont.—A recent fire damaged one of the buildings of the Canadian General Electric Co. to the extent of several thousand dollars.

Pickering, Ont.—It is stated that the Provincial Highways Department will erect a machine shop and warehouse here in connection with the building of the eastern division of the provincial highway in these districts.

Portage la Prairie, Man.—A movement is on foot for the erection of a skating rink. Estimated cost, $30,000. Clerk, W. R. Grieve.

Quebec, Que.—A building permit has been issued to Paquet and Co. for the erection of a six-story fireproof steel structure on DesFosses St. Estimated cost, $150,000.

Quebec, Que.—The Champlain Brewery Co. propose to build a new structure at the corner of Crown and Prince Edward Streets. Estimated cost, $100,000.

Quebec, Que.—Damage ranging between $15,000 and $20,000 was caused by fire recently in the Le Mesurier tobacco factory.

Regina, Sask.—City council has agreed to sell the Ford Motor Co. of Canada, Ltd., a site on which the company will erect a $100,000 assembling plant. Construction work will likely commence next spring.

Regina, Sask.—The Saskatchewan Grain Growers may purchase a site from the city for the erection of a large warehouse.

Regina, Sask.—The Williams Motor Co. will build a distributing warehouse and office building on Cornwall St. East. The estimated cost is $20,000. Plans are being prepared by Storey and Van Egmond, and tenders will be called shortly.

Saskatoon, Sask.—A building permit has been issued to W. F. Langstaff, of the Western Fruit Co., for a $3,000 basement construction on 4th Ave. North.

South Vancouver, B.C.—The building of a high school here is imperative, according to the report of the special committee appointed to inquire into the high school situation. Chairman of the special committee, Allen E. Chamberlain.

St. John's, Nfld.—Contract has been let to B. Bowering for the enlargement of the government Tuberculosis Sanatorium on Topsail Rd., and work has started.

St. John, N.B.—The St. John housing board let contract to Rourke and Griffiths, West St. John, for the erection of four self-contained and four semi-detached houses at a total price of $43,240.

St. Thomas, Ont.—Appleford's, Ltd., propose to erect a factory in this city.

St. Thomas, Ont.—It is reported that negotiations have been started by a Toronto firm for a site on Talbot St. on which to erect a large hotel.

Sydney, N.S.—Contract for the erection of a large hotel has been awarded to the Fuller Construction Co., who have already started work.

Smith's Falls, Ont.—The town council has given the first reading to a by-law providing for the borrowing of $60,000 from the provincial government under the Housing Act.

Toronto, Ont.—An offer was placed before the Property Committee of the Board of Education last week for the purchase of the vacant site on the north side of Bloor St. East, opposite St. Paul's Church, to be used for the erection of a large $5,000,000 family hotel. The offer was made by W. J. Hambly on behalf of an American concern.

Toronto, Ont.—G. W. Lucas, 98 Bathgate Ave., has been granted a permit to erect five three-story stores, costing $50,000 on Danforth Ave., near Broadview.

Toronto, Ont.—Separate tenders addressed to T. L. Church, chairman of the board of control, for the work included in the specifications of the several trades mentioned below in connection with the erection and completion of public lavatories at Centre Island, Toronto, will be received up to noon on Tuesday, October 21st, 1919: (1) Mason work; (2) carpenter work; (3) plumbing work; (4) electric wiring and fixtures; (5) plastering; (6) painting. Plans and specifications may be seen at the office of the city architect, City Hall, Toronto.

Toronto, Ont.—The Bank of Nova Scotia has purchased a site at the south-west corner of Queen and Church Sts., for the erection of a branch bank building.

Toronto, Ont.—The Industrial Education Committee has appealed to the city council for the erection of a technical school in the east end of the city.

Toronto, Ont.—Two new bank buildings will be erected in the near future, one being the new Toronto head office of the Merchants Bank at 12-16 King St. West, and a branch of the Dominion Bank on the east side of Yonge, near Hayden St.

Vancouver, B.C.—A permit has been issued to Allan and McKelvie to build an erecting shop at 1214 Pender St. East at a cost of $2,000.

Vancouver, B.C.—A movement is on foot for the erection of a combination Hebrew school and synagogue at an approximate cost of $40,000. For further information address Max M. Grossman.

Victoria, B.C.—Contract has been let for erection of Alberni Indian School to Parfitt Brothers at a cost of $65,000.

Vancouver, B.C.—The Restmore Manufacturing Co. have taken out a permit for $10,000 to build a boiler house and tempering office for their factory at the corner of Parker St. and Glen Drive.

Waterloo, Ont.—An addition to the building of the Mutual Life Assurance Co. of Canada is to be erected immediately.

Welland, Ont.—A plan is on foot by the members of the city and county councils and Great War Veterans' Association for the erection of a $125,000 memorial building. A committee has been appointed of which T. J. Dillon is chairman.

Winnipeg, Man.—A building permit has been issued to the Swift Canadian Co., for the erection of an icehouse on Midwinter St. at a cost of $5,000.

Winnipeg, Man.—Tenders addressed to the chairman, committee on library and public baths, will be received at the office of C. J. Brown, city clerk, up to 3 p.m., October 22nd, 1919, for the supply of labor and materials required in the work of alterations to the dressing-rooms at the Charles St. public baths. Specification may be obtained at the office of the building inspector, corner James Ave. and King St.

Winnipeg, Man.—The Ogilvie Flour Mills Co. will erect a storage shed on Higgins Ave. at a cost of $5,000, and the Salvation Army will erect a citadel on the south-east corner of East St. and Alexander Ave. at a cost of $6,500.

MISCELLANEOUS

Barton Township, Ont.—Ratepayers will vote on a by-law at the next municipal elections for the purchase of stone-crushing equipment. Clerk, A. G. E. Bryant, Hamilton, Ont.

Brandon, Man.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Tuesday, October 21st, 1919, for the construction of a new passage between post-office

Every Construction Engineer Should Have

Kidder's Architects' and Builders' Pocket Book

16th Edition, Rewritten, by Thomas Nolan and a Staff of Specialists.

Is recognised by engineers, architects and contractors the world over as the foremost reference book in its line.

Complete in every detail, authoritative and reliable, it should occupy a convenient place on YOUR desk. A few of the good things you will find in it are: Information on Masonry Walls, Cements and Concrete, Tension and Properties of Iron and Steel, Roof Trusses, Fire-proofing of Buildings, Reinforced-Concrete Construction, Foundations, Wind-Bracing for Tall Buildings, Retaining Walls, Reactions and Bending Moments for Beams, etc.

How to Waterproof

WALLS DAMS TUNNELS
ROOFS FLOORS CONCRETE DOCKS

in fact, all kinds of structures, is fully and authoritatively explained in

Waterproofing Engineering

By Joseph Ross, B.S., C.E. This very important new book should be in the hands of all construction engineers and contractors.

x. + 442 pages. 6 by 9. 138 figures. Cloth, $5.00 net.

and old bank building, and additional post-office fittings in post-office. Plans and specification may be seen at the offices of the Chief Architect, Department of Public Works, Ottawa; the Resident Architect, Lindsay Building, Winnipeg, Man., and the postmaster, Brandon, Man.

Montreal, Que.—A great North American shipbuilding entente between Canada and the United States is foreshadowed by the visit to Montreal recently of David Rodgers, general works manager of the Skinner and Eddy Corporation, Seattle. A part of the scheme is the establishment of a shipbuilding yard at Montreal and at several other points throughout Canada, involving an outlay of millions of dollars. It is understood that contracts for nearly $400,000,000 worth of ships are practically pledged to the proposed company.

Montreal, Que.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, and endorsed, "Tender for Montreal, Verdun Postal Station Fittings," will be received until 12 o'clock noon, Thursday, October 23rd, 1919. Plans and specifications may be seen at the offices of the Chief Architect, Department of Public Works, Ottawa, and the Overseer of Dominion Buildings, Montreal, Que.

Oshawa, Ont.—Town council gave third reading to by-laws providing for pavements and sanitary sewers on certain streets. Town engineer, G. W. Worden.

Pointe aux Trembles, Que.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Wednesday, November 5th, 1919, for repairs to landing pier. Plans may be seen and specifications obtained at the Department of Public Works, Ottawa; at the offices of the District Engineers, Post-office Building, Quebec, Que.; Shaughnessy Building, Montreal, Que., and at the post-office, Pointe aux Trembles, Que.

St. Francois Sud, Que.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Wednesday, November 5th, 1919, for the construction of repairs to the wharf. Plans may be seen and specification obtained at the Department of Public Works, Ottawa; at the offices of the District Engineers, Post-office Building, Quebec, Que.; Shaughnessy Building, Montreal, Que., and at the post-office, St. Francois d'Orleans, Que.

St. John, N.B.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Thursday, October 23, 1919 for the construction of grain conveyer equipment, at Berth 15, St. John Harbor, N.B. Plans of contract may be seen and specification obtained at the Department of Public Works, at the offices of the engineer-in-charge, St. John, N.B., district engineers, Shaughnessy Building, Montreal, and Equity Building, Toronto.

Winnipeg, Man.—It has been reported that the Flin Flon low-grade copper mine in northern Manitoba has been bought by Hayden, Stone and Co., of Boston, at a price said to have run into the hundreds of millions of dollars. It is understood that the new owners will proceed at once to build in a railway at an estimated cost of $2,000,000 and erect a $5,000,000 smelter on the property.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, October 20th, 1919, for the supply of labor and materials required for overhauling and renewing the plumbing at the waterworks office at the city yards. Specification may be obtained at the office of the Operating Superintendent of Waterworks, 223 James Ave.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Library and Public Baths, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Wednesday, October 22nd, 1919, for supply of all labor and materials required in the construction of certain tile work at the Cornish Park Baths. Specification may be obtained at the office of the Building Inspector, corner James Ave. and King St.

Tenders Called For

CITY OF LONDON, ONTARIO

TENDER FOR MOTOR-DRIVEN STREET FLUSHER

Sealed tenders, addressed to the "Chairman and Members, No. 2 Committee," will be received at the office of the City Clerk up to 3 p.m. on Monday, October 27th, 1919, for the supply of one 1,200 U.S. gallon capacity Motor-driven Street Flusher, complete.

Specifications and form of tender, etc., may be obtained at the office of the City Engineer.

Tenders to be accompanied by a marked cheque or a cash deposit for 5% of the amount of tender.

The lowest or any tender not necessarily accepted.

C. R. SOMERVILLE, Mayor. H. A. BRAZIER, City Engineer.

W. A. WILSON, Acting Chairman, No. 2 Committee. 363

Condensed Advs.

Advertisements under this heading at following rates per insertion, with fifty cents per insertion as minimum rate in any case; "Positions Wanted," one cent per word; all other condensed advertisements, three cents per word. Payable in advance; 50 per cent. extra if charged.

GOOD OPENING for ambitious young man, graduate in Mechanical Engineering, preferably under thirty years of age. Canada Forge Co., Welland. 362

RETURNED OFFICER.—Civil Engineer; wants work to do at home; Tracing; Drafting; Quantities; Designing. Box 17, *The Canadian Engineer*, Toronto.

ENGINEER WANTED to take charge of a Buffalo office of a Canadian engineering and contracting firm doing contract work. Duties are partly engineering and partly selling. Good opportunity for live man. Address Box 13, *Canadian Engineer*, Toronto.

MANUFACTURER in Eastern Townships, having good facilities and considerable experience in the production of a wide variety of machinery lines, desires to undertake the manufacture (for the Canadian or export trade) of American or English machinery. Full particulars gladly upon request. Box 396, *Canadian Engineer*, Toronto.

ENGINEER WANTED to take charge of Engineering Department for large pulp and paper company who are making large extension to their development. He must have a good education and years of experience in similar position. He must have good executive ability, experience in making out specifications and contracts and in buying. Salary, $10,000 a year. With applications pleace give information in detail as to education, experience, age, married or single, and copy of references. Address Box 15, *Canadian Engineer*, Toronto.

COMMISSARY work for construction undertakings is my specialty. Before entering this line, I had eight years' experience as an accountant in the Canadian Bank of Commerce in Toronto and other Canadian cities. Am a Canadian, married, good references. During last year of war had entire charge of all feeding and living accommodations, timekeeping, etc., for large shipbuilding corporation in United States. Interview solicited. Address Box 398, *Canadian Engineer*, Toronto.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Classification and Salaries of Engineers

Toronto Engineers Adopt Schedule of Titles, Qualifications and Minimum Salaries for Technically-Trained Men Employed by Railways, Municipalities, Industries, Public Works and Large Public Utilities—Salaries Range from $1,200 to $12,000 Per Annum

AT a meeting held last Thursday evening, the members of the Toronto branch of the Engineering Institute of Canada approved of the schedule prepared by the Salaries Committee of that branch. This schedule classifies engineers employed by railways, municipalities, industrial firms, large public utilities and the Public Works Department of Canada. It groups the engineers employed in these five lines of work in clear-cut classes, with non-conflicting titles, and states the qualifications deemed requisite for each class, and also states the minimum salary which, in the opinion of the members of the branch, should be paid to each class.

In some of the classifications, the minimum salary stated in the schedule does not exceed that which prevails at present on the most important works in Canada, but in general the classification, if adopted by employers, will mean a most substantial increase for many engineers, especially when it is borne in mind that the salary mentioned in the schedule is meant to be the minimum salary to be paid in any case.

The schedule, having now been adopted by the Toronto branch, will be sent to every one of the other branches of the Institute throughout Canada for comment and to aid them in the preparation of similar schedules. Many of the other branches of the Institute have committees at work upon similar schedules, although no other branch, so far as is known, has as yet definitely completed a schedule. The Niagara Falls, Ont., branch is said to have made very great progress in the preparation of a schedule. The branches in the maritime provinces and also many of those in the western povinces have discussed the desirability of uniform classification.

The Toronto schedule will also be forwarded to the council of the Institute at Montreal, with a recommendation that it be formally adopted by the Institute as a whole.

Personnel of Salaries Committee

The personnel of the Salaries Committee of the Toronto branch is as follows:—

Geo. Clark (chairman), designing engineer, Toronto Harbor Commission; H. A. Goldman (secretary), assistant engineer, Toronto Harbor Commission; L. M. Arkley, assistant professor of mechanical engineering, University of Toronto; N. L. Crosby, contracting engineer, Toronto Structural Steel Co.; F. B. Geodike, assistant engineer, railway department, Hydro-Electric Power Commission of Ontario; E. G. Hewson, railway engineer, Hydro-Electric Power Commission of Ontario; Thomas Hogg, assistant hydraulic engineer, Hydro-Electric Power Commission of Ontario; H. J. Lamb, superintending engineer for Ontario, Department of Public Works of Canada; James Milne, mechanical and electrical engineer, works department, city of Toronto; G. G. Powell, deputy city engineer, Toronto; A. F. Stewart, chief engineer, Canadian National Railways; and Thomas Taylor, designing and construction engineer, Bloor St. Viaduct, Toronto.

Andrew Harkness, consulting structural engineer, Toronto, who is chairman of the Toronto branch, and W. S. Harvey, engineer of sewers, Toronto Harbor Commission, who is secretary of the Toronto branch, are ex-officio members of the committee.

Approximately, 60 members of the branch were present at the meeting last Thursday evening, Mr. Harkness presiding. After the routine business had been quickly finished, Mr. Clark was asked to present the report of the Salaries Committee, which had been considering the proposed classification and schedule of salaries for the past six months.

After Mr. Clark had read the schedule in regard to railway work, Mr. Harkness enquired regarding the present rate of pay received by railway brakemen, and was informed by Mr. Clark that it amounts to between $300 and $330 per month.

J. R. W. Ambrose, chief engineer of the Toronto Terminal Railway Co., enquired as to how the schedule of salaries recommended by the committee compares with the schedule used by the American Association of Engineers, and was informed that the proposed Toronto schedule is about $200 per annum higher than that of the American Association.

Railway Salaries are Discussed

The only change made in the railway classification was to substitute the title "Designing Engineer in Structural Department," for "Leading Draftsman in Structural Department."

Mr. Ambrose contended that rodmen should receive more than chainmen, as they are considered on the railways to be superior to chainmen. Mr. Clark, however, expressed the opinion that men employed for this class of work are largely from high schools or else are junior students at the universities, and may all be considered as equal in ability, but the members decided to support the increase for rodmen as proposed by Mr. Ambrose.

The railway salaries reported by the committee were unanimously adopted excepting for the following changes: Assistant Bridge Engineer $4,800 instead of $4,200; Designing Engineer in Structural Department, $3,600 instead of $3,000; Rodman, $1,500 instead of $1,200.

Frank Barber, consulting engineer, Toronto, enquired as to how officials such as county engineers and road commissioners should be scheduled in view of the fact that some of them are only employed part time and that others are not qualified engineers, and that the conditions of employment differ so greatly in the various cases. Mr. Clark stated that these matters are covered by the municipal schedule.

J. C. Krumm, railway bridge designer, Hydro-Electric Power Commission of Ontario, said that in respect to bridge engineers the railway schedule does not conform to what he considers to be the usual distinction between the various classes of technically-trained men, and he proposed that the schedule be referred back to the committee for revision. This was not carried, however, as G. A. McCarthy, engineer of railways and bridges, city of Toronto, and many other expressed the view that the classification regarding bridge engineers is satisfactory and should not be changed.

Mr. McCarthy objected, however, to the qualification requiring bridge engineers to be college graduates; he thought that it would be somewhat severe to confine future appointments in bridge work solely to men who are graduates of universities. He stated that he knows some very able bridge engineers who are not college graduates. He moved, with Mr. Ambrose as seconder, that the wording "should be a college graduate" be changed to "should preferably be a college graduate," and it was decided to make this change throughout all of the classifications excepting that relating to public works. The public works classification is that which had been adopted by the Civil Service Commission of Canada, and it had been accepted in its entirety by the Salaries Committee of the Toronto branch, therefore no changes were made in the classification relating to that field of work.

Discussion on Municipal Salaries

After Mr. Clark had read the schedule relating to municipal work, R. E. W. Hagarty, consulting engineering Toronto, expressed the opinion that the salaries should be increased by 25%, especially the lower salaries. George Hogarth, chief engineer, Ontario Highways Department and and R. O. Wynne-Roberts, consulting engineer, Toronto, believed that the salaries of deputy city engineers, first assistants and second assistants should be increased.

Mr. Clark stated that the present depreciation in value of the dollar should not be taken too much into account in determining a permanent schedule of minimum salaries, and that due regard should be paid to the circumstances of individual employment and to the value of services rendered in other fields of engineering work of similar nature. After debate, the members decided to add $600 per annum to the salary of chief engineers of municipalities of less than 100,000 population, $400 per annum to the salary of first assistants in cities between 100,000 and 300,000 population, and $600 per annum to the salary of designers.

F. A. Dallyn, sanitary engineer, Ontario Board of Health, expressed the opinion that the experience required is just as great for cities of 7,000 population as for those of 10,000 population, and he thought the dividing point should be at 7,000 instead of 10,000. No motion to this effect was made, however.

Public Works Schedule Altered

The industrial, public utilities and public works schedules were adopted without much discussion, no changes being made in the industrial or public utilities schedules. It was emphasized, however, that the classification and salaries mentioned for public utilities can be considered effective only for the larger type of public utilities, and that it is not practical at present to recommend their strict observance by small public utilities.

In the public works schedule, the following changes in salaries were made: Senior Assistant Engineer, $3,200 instead of $2,700; Resident Engineer, $3,140 instead of $2,640; Chief Draughtsman, $2,500 instead of $2,280; Inspector, $1,800 instead of $1,500; Draughtsman, $1,500 instead of $1,200; Junior Instrumentman, $1,500 instead of $1,200.

Following is the schedule as finally adopted by the Toronto branch, the salary figures mentioned in each case being the minimum salary, which in the industrial schedule is supposed to be graded according to the size of the industry:—

Railway Schedule

1. Chief Engineer, $10,000.
2. Assistant Chief Engineer, $7,200.

3a. Engineer of Maintenance, $6,600. Should preferably be a graduate from an engineering school recognized by the Institute, and should have 8 to 10 years' practical experience in engineering work, or, if not a graduate, should have from 12 to 15 years' practical experience, and should be thoroughly familiar with the mathematics of engineering.

3b. Engineer of Construction, $6,600. Same qualification as for Engineer of Maintenance.

3c. Bridge Engineer, $6,000. Same qualification as for Engineer of Maintenance.

3d. Principal Assistant Engineer, $6,000. Same qualification as for Engineer of Maintenance.

4a. District Engineer, $4,800. Should preferably be a graduate from an engineering school recognized by the Institute, and should have 6 to 8 years' practical experience in engineering work, or, if not a graduate, should have from 10 to 12 years' practical experience, and should be familiar with the mathematics of engineering.

4b. Signal Engineer, $4,800. Should preferably be thoroughly familiar with the theory and practice of signalling, and of train operation, and should have had, in addition, at least five years' practical experience in mechanical and electrical signal work on railways.

4c. Architect or Engineer of Buildings, $4,000. Should have sufficient architectural training to design railway stations, shops, round-houses, dwellings, etc., of normal types, and should have 6 or 8 years' practical experience in responsible design of railway buildings.

4d. First Assistant Engineer, $4,200. Same qualification as for District Engineer.

4e. Assistant Bridge Engineer, $4,800. Should preferably be a graduate engineer with from 5 to 6 years' practical experience in the office and in the field.

5a. Division Engineer, $3,600. Should preferably be a graduate engineer with 3 or 4 years' experience of practical engineering, or, if not a graduate, should have 8 to 10 years' practical experience and should be well grounded in the mathematics of engineering.

5b. Second Assistant Engineer, $3,000. Same qualification as for Division Engineer.

5c. Chief Draughtsman, $2,500. Should have a thorough knowledge of general draughting, but not necessarily knowledge of design, and should be able to control a number of subordinates and supervise their work.

5d. Designing Engineer in structural department, $3,600. Should be thoroughly grounded in the theory of design and detail in his particular department, and should be able to control a number of subordinates and supervise their work.

5e. Leading Draughtsman in architectural department, $2,400. Same qualification as given for Designing Engineer in structural department.

5f. Signal Supervisor, $2,400. Should be thoroughly familiar with the mechanical and electrical details of signalling, should have sound elementary knowledge of the principles of signalling, and should be qualified to carry out and supervise construction and maintenance of all types of signal plants.

6a. Resident Engineer (construction only), $2,700 and expenses. Should preferably be graduate engineer or have 3 or 4 years' practical experience in the junior branches of engineering work.

6b. Third Assistant Engineer, $2,400. Same qualification as for Resident Engineer.

6c. Draughtsman, $1,800. Should be able to plot accurately from field notes or notes and sketches supplied to him by a senior officer.

6d. Inspector (class A), $2,400 and expenses. Should have a thorough knowledge of the class of work that he is employed to inspect, and in the case of steel or reinforced concrete structures, should be a man of sufficient intelligence to understand the elementary principles of design and realize the necessity for close adherence to plans, and must be able to read and interpret plans correctly.

7a. Junior Assistant or Instrument Man, $1,800 and expenses. Should have sufficient training in the use of level or transit, or both, to do accurate work at a reasonable rate of speed, and should be thoroughly grounded in the mathematics required

for the proper reduction and application of his instrumental work.

7b. Inspector (class B), $1,800. Should have some practical experience in the class of work that he is employed to inspect, and have sufficient intelligence and firmness to enforce the carrying out of specifications.

7c. Junior Draughtsman, $1,500. Should have passed through his training as a tracer, and should have working knowledge of the use of draughting instruments.

8a. Chainman, $1,200. No previous experience required.

8b. Rodman, $1,500. No previous experience required.

8c. Tracer, $1,200. No previous experience required.

Municipal Schedule

1a. Chief Engineer of municipality greater than 300,000 population, $12,000. Should preferably be a graduate from an engineering school recognized by the Institute, and should have had 15 years' practical experience, covering two branches in municipal engineering, and should have served for about 5 years in the capacity of Deputy City Engineer, or of First Assistant in municipalities of over 300,000, or as Chief Engineer in municipalities of over 100,000, and should possess proven executive ability.

1b. Chief Engineer, 100,000 to 300,000, $8,000. Should preferably be a graduate with 10 years' experience, covering two branches in municipal engineering. Three years of his experience should be in the capacity of either one of the following:—Chief Engineer in municipality of over 50,000, First Assistant in municipality of over 100,000, or Second Assistant in municipality of over 300,000. He should possess proven executive ability.

1c. Chief Engineer, 50,000 to 100,000, $6,600. Should preferably be a graduate with 8 years' experience in municipal engineering, 2 years of which should be in the capacity of any one of the following:—Chief Engineer in city of over 10,000, First Assistant in city less than 100,000, or Second Assistant in city under 300,000. He should possess proven executive ability.

1d. Chief Engineer, 25,000 to 50,000, $5,400. Should preferably be college graduate or licensed land surveyor with 5 years' experience in municipal engineering, and possess proven organizing ability.

1e. Chief Engineer, 10,000 to 25,000, $4,200. Should preferably be college graduate or licensed land surveyor with 3 years' experience in municipal engineering, or should have completed apprenticeship to municipal engineer, and have been subsequently placed in responsible charge of engineering work. He must have ability to handle men.

1f. Chief Engineer, less than 10,000, $3,000. Same qualifications as for cities between 10,000 and 25,000 unless work is confined to routine construction and maintenance, in which case he should have had 5 years' experience as First Assistant in similar work, and should have ability to handle men.

1g. Other Municipal Engineers (employed part time), Daily Rate. Land Surveyors,—requirements prescribed by law. For routine construction and maintenance, qualification to be same as for Chief Engineer of city less than 10,000. Other casual work probably done by consulting engineers.

2. Deputy City Engineer or Principal Assistant in cities over 300,000, $8,000. Same qualification as for Chief Engineer in city of from 100,000 to 300,000.

3a. First Assistant having charge of (any one of the following) roadways, sewers, water works, light, transportation, structures, testing and inspection in cities over 300,000, $5,000. Should preferably be a graduate with 8 years' experience in municipal engineering, 4 years of which should have been in the capacity of First Assistant in municipality of 100,000 to 300,000, or, as Second Assistant in municipality of over 300,000. Should be able to handle office, construction and maintenance forces.

3b. First Assistant in charge of one or more departments in cities 100,000 to 300,000, $4,000. Should preferably be a graduate with 6 years' experience in engineering, 2 years of which should have been in the capacity of First Assistant in city of less than 100,000, or, as Second Assistant in city of over 100,000. Should be able to handle office, construction and maintenance forces.

3c. First Assistant in cities less than 100,000, $3,000. Should preferably be a graduate with 4 years' experience in engineering, 2 years of which should have been in the capacity of Second Assistant, and should be able to handle office, construction and maintenance forces.

4a. Second Assistant reporting to the First Assistants in larger municipalities and to the Chief Engineer in smaller municipalities, in responsible charge of design, drafting and engineering records, cities over 300,000, $3,600. Should preferably be a graduate with 6 years' experience in engineering, 4 years of which should have been as Second Assistant in city under 300,000, or as Resident Engineer on construction with designing experience, or as Designer. Should be able to handle office staff for designing, drafting and keeping records.

4b. Second Assistant in responsible charge of design, drafting and engineering records, cities less than 300,000, $3,000. Should preferably be a graduate with 4 years' experience in engineering, 2 years of which should have been either as Designer or as Resident Engineer on construction with designing experience. Should be able to handle office staff for designing, drafting and keeping of records.

4c. Second Assistant in responsible charge of surveys, cities over 300,000, $3,000. Should preferably be a graduate engineer or licensed land surveyor with 4 years' experience as Instrument man in municipal work, preferably on construction, and should be able to handle several parties and to keep them employed to advantage.

4d. Second Assistant in responsible charge of surveys, cities less than 300,000, $2,400. Should preferably be a graduate engineer or licensed land surveyor with 2 years' experience as Instrument man in municipal work, preferably on construction, and should be able to handle several parties and keep them employed to advantage.

4e. Second Assistant in responsible charge of construction, operation or maintenance (one or more), cities more than 300,000, $3,600. Should preferably be a graduate with 6 years' experience in engineering, 4 of which should have been as Inspector or as Resident Engineer on construction, and should be able to handle construction and maintenance forces.

4f. Second Assistant in responsible charge of construction, operation or maintenance (one or more), cities less than 300,000, $3,000. Should preferably be a graduate with 4 years' experience in engineering, 2 of which should have been as Inspector or as Resident Engineer on construction, and should be able to handle construction and maintenance forces.

5. Resident Engineer on construction, $2,400. Should preferably be graduate with 3 years' experience in municipal work, or should have completed apprenticeship in municipal work. Should have ability to use survey instruments, make calculations arising therefrom, and keep track of quantities and labor.

6. Designer, $3,000. Should preferably be a graduate with 4 years' experience, and should be familiar with the mathematics and practice of the branch of work in question.
7. Draughtsman, $1,800. Should be high school or preferably a college graduate, and should be able to plot accurately from field notes and produce correct working drawings from designer's sketches and computations.
8. Inspector, $2,100. Should have a thorough knowledge of the class of work that he is employed to inspect, and in the case of steel or reinforced concrete structures, should be a man of sufficient intelligence to understand the elementary principles of design and realize the necessity for close adherence to plans, and must be able to read and interpret plans correctly.
9. Instrument Man, $1,800. Should be high school or preferably a college graduate and should have sufficient training in the use of level or transit, or both, to do accurate work at a reasonable rate of speed, and should be thoroughly grounded in the mathematics required for the proper reduction and application of the instrumental work. In case of construction he should understand the special requirement for the class of work in question.
10. Chainman or Rodman, $1,200. No previous experience required.
11. Tracer, $1,200. No previous experience required.

Industrial Schedule

1a. Chief Engineer, $10,000 down to $3,600.
1b. Research Engineer, $10,000 down to $3,600. Should preferably be a graduate from an engineering school recognized by the Institute, with from 10 to 15 years' experience in his special line.
1c. Mechanical Engineer, $10,000 down to $3,600. Same qualification as for Research Engineer.
1d. Electrical Engineer, $10,000 down to $3,600. Same qualification as for Research Engineer.
1e. Chemical Engineer, $10,000 down to $3,600. Same qualification as for Research Engineer.
1f. Metallurgical Engineer, $10,000 down to $3,600. Same qualification as for Research Engineer.
2a. Assistant Chief Engineer (in large industries only), 75% of salary of Chief Engineer, with a minimum of $3,000. Preferably technical graduate with from 5 to 10 years' experience.
2b. Engineer in general charge of all outside construction, 75% of salary of Chief Engineer, with a minimum of $3,000. Preferably technical graduate with from 5 to 10 years' experience.
2c. Efficiency Engineer (usually a consulting engineer, but occasionally on the permanent staff), 75% of salary of Chief Engineer, with a minimum of $3,000.
3a. Designing Engineer, having responsible charge of all design in mechanical engineering, 50% of salary of Chief Engineer, with a minimum of $2,700. Should preferably be a technical graduate with 5 years' practical experience in his special line, or, should be a high school graduate with 10 years' practical experience, and should have a good general knowledge of mathematics and the fundamental physical laws used in engineering.
3b. Designing Engineer, having responsible charge of all design in electrical engineering, 50% of salary of Chief Engineer, with a minimum of $2,700. Same qualification as for mechanical engineering.
3c. Designing Engineer having responsible charge of all design in structural engineering, 50% of salary of Chief Engineer, with a minimum of $2,700. Same qualification as for mechanical engineering.
3d. Designing Engineer having responsible charge of all design in heating and ventilating engineering, 50% of salary of Chief Engineer, with a minimum of $2,700. Same qualification as for mechanical engineering.
4a. Engineer in charge of estimating, figuring costs, etc., 35% of salary of Chief Engineer, with a minimum of $2,400. Should preferably be a technical graduate with 3 years' practical experience in his special line, or, should be a high school graduate with 8 years' practical experience, and should have a good general knowledge of mathematics and the fundamental physical laws used in engineering.
4b. Testing Engineer in charge of tests, 35% of salary of Chief Engineer, with a minimum of $2,400. Same qualification as for Engineer in charge of estimating.
4c. Resident Engineer on construction, 35% of salary of Chief Engineer, with a minimum of $2,400. Same qualification as for Engineer in charge of estimating.
4d. Chief Draughtsman responsible for all working drawings, 35% of salary of Chief Engineer, with a minimum of $2,400. To be qualified by training and experience for the special work required of him.
4e. Designer, assistant to Designing Engineer, 35% of salary of Chief Engineer, with a minimum of $2,400. Should preferably be a technical graduate with 2 years' practical experience, or should be a high school graduate with 4 years' practical experience, and should have a good general knowledge of mathematics and the fundamental physical laws used in engineering.
5a. Estimator, assistant to Engineer in charge of estimating, $2,400. Should preferably be a technical graduate with 2 years' practical experience, or should be a high school graduate with 3 years' practical experience, and should have a good general knowledge of mathematics and the fundamental physical laws used in engineering.
5b. Squad Boss in charge of small squad of Draughtsmen, $2,400. Should be a high school graduate with 3 years' practical experience, 1 year as checker, and should have a good general knowledge of mathematics and the fundamental physical laws used in engineering.
6a. Chief Shop Inspector in charge of shop inspection, $2,100. Should preferably be a technical graduate with 1 year's experience, or should be a high school graduate with 3 years' experience as inspector, and should have a good general knowledge of mathematics and the fundamental physical laws used in engineering.
6b. Checker, responsible for the correctness of working drawings, $2,100. Similar qualification as for Chief Shop Inspector.
7a. Draughtsman, making detailed working drawings, $1,800. Should preferably be a technical graduate, or 3 years' experience in drawing, tracing, etc.
7b. Shop Inspector, $1,800. Should have some practical experience in the class of work that he is employed to inspect, and have sufficient intelligence and firmness to enforce carrying out of specifications.
7c. Field Inspector, $1,800. Same qualification as for Shop Inspector.
8. Tracer, $1,200. No previous experience required.

Public Utility Schedule

1. Chief Engineer, $12,000.
2. Assistant Chief Engineer, $9,000.
3a. Departmental Engineer having charge of surveys, specifications for and design of hydraulic structures, drafting and engineering records, and hydrometric records, $7,500. Should preferably be a graduate from an engineering school recognized

by the Institute, with from 10 to 15 years' experience in his particular work.

3b. Departmental Engineer having charge of specifications for, and design of, electrical work, substations, powerhouses and switching stations, $7,500. Same qualifications as for 3a.

3c. Departmental Engineer having charge of surveys and design of transmission lines, high tension and low tension, $5,000. Same qualifications as for 3a.

3d. Departmental Engineer having charge of construction, $7,500. Should preferably be a graduate from an engineering school recognized by the Institute, with from 10 to 15 years' experience on construction, with requisite executive ability to organize and handle large forces of men on the various works indicated by 3a, 3b and 3c.

3e. Departmental Engineer having charge of research and tests, $5,000. Same qualifications as for 3a.

3f. Departmental Engineer having charge of operation and maintenance, $7,500. Same qualifications as for 3a.

3g. Departmental Engineer having charge of power contracts, $5,000. Same qualifications as for 3a.

4a. Deputy Departmental Engineer having charge of surveys, specifications for and design of hydraulic structures, drafting and engineering records and hydrometric records, $4,800. Should preferably be a graduate from an engineering school recognized by the Institute, with 8 years' experience in his particular work.

4b. Deputy Departmental Engineer having charge of specifications for and design of electrical work, substations, powerhouses and switching stations, $4,800. Same qualifications as for 4a.

4c. Deputy Departmental Engineer having charge of surveys for and design of transmission lines, high tension and low tension, $3,000. Same qualifications as for 4a.

4d. Deputy Departmental Engineer having charge of construction, $4,800. Same qualifications as for 4a.

4e. Deputy Departmental Engineer having charge of research and tests, $3,000. Same qualifications as for 4a.

4f. Deputy Departmental Engineer having charge of operation and maintenance, $4,800. Same qualifications as for 4a.

4g. Deputy Departmental Engineer having charge of power contracts, $3,000. Same qualifications as for 4a.

5a. Assistant Departmental Engineer having charge of design of hydraulic structures and records, $3,600. Should preferably be a graduate from an engineering school recognized by the Institute, with 4 years' experience in his particular work.

5b. Assistant Departmental Engineer having charge of power surveys and field engineering on construction, $3,000. Same qualifications as for 5a.

5c. Assistant Departmental Engineer having charge of hydrometric investigation and records, $2,400. Same qualifications as for 5a.

5d. Assistant Departmental Engineer having charge of specifications for and design of electrical work, $3,600. Same qualifications as for 5a.

5e. Assistant Departmental Engineer having charge of specifications for and design of buildings, $3,000. Same qualifications as for 5a.

5f. Assistant Departmental Engineer having charge of field engineering on construction, $2,400. Same qualifications as for 5a.

5g. Assistant Departmental Engineer having charge of design of high tension lines, $3,000. Same qualifications as for 5a.

5h. Assistant Departmental Engineer having charge of design of low tension lines, $2,700. Same qualifications as for 5a.

5i. Assistant Departmental Engineer having charge of surveys for and field engineering on transmission lines, $2,400. Same qualifications as for 5a.

5j. Assistant Departmental Engineer having charge of construction of hydraulic structures, $3,000. Same qualifications as for 5a.

5k. Assistant Departmental Engineer having charge of construction of electrical work, $3,000. Same qualifications as for 5a.

5l. Assistant Departmental Engineer having charge of construction of building, $2,400. Should be a high school graduate with 5 years' experience in building trades.

5m. Assistant Departmental Engineer having charge of electrical testing, $2,400. Same qualifications as for 5a.

5n. Assistant Departmental Engineer having charge of structural testing, $2,400. Same qualifications as for 5a.

5o. Assistant Departmental Engineer having charge of chemical testing, $2,400. Same qualifications as for 5a.

5p. Assistant Departmental Engineer having charge of field and shop inspection, $2,400. Same qualifications as for 5a.

5q. Assistant Departmental Engineer having charge of operations of district or system, $3,000. Same qualifications as for 5a.

5r. Assistant Departmental Engineer having charge of power contracts of district or system, $2,400. Same qualifications as for 5a.

5s. Assistant Departmental Engineer having charge of right-of-way surveys, $2,700. Same qualifications as for 5a, and should hold his provincial land surveyor's certificate.

5t. Assistant Departmental Engineer having charge of cost estimates and power estimates, $2,400. Same qualifications as for 5a.

6. Designer or layout man, $2,400. Should preferably be a graduate from an engineering school recognized by the Institute with 2 years' experience.

7. Draughtsman, Instrument Man and Inspector, $1,800. Should preferably be a technical graduate, or 3 years' experience.

8. Tracer and Chainer, $1,200. No previous experience required.

Public Works Schedule

1. Chief Engineer, $12,000. Graduation in engineering from a school of applied science of recognized standing; at least 12 years of experience in engineering survey, design, estimate and construction work, 7 years of which shall have been in responsible charge of such work; thorough knowledge of Canadian engineering problems; the highest degree of administrative ability.

2. Assistant Chief Engineer, $8,000. Graduation in engineering from a school of applied science of recognized standing; at least 10 years of experience in engineering design, estimate, construction and maintenance work, 5 years of which shall have been in responsible charge of such work; thorough knowledge of dredging work and the general engineering problems of Canada; ability to organize, supervise, and manage large engineering works.

3. Supervising District Engineer, $6,000. Education equivalent to graduation in engineering from a school of applied science of recognized standing; at least 7 years of experience in engineering survey, design, estimate, construction and maintenance work, 4 years of which shall have been in responsible charge of such work; considerable knowledge of marine engineering work; ability to make constructive criticisms and reports on proposed works and supervise the construction of large works.

4. Senior Engineer, $5,000. Education equivalent to graduation in engineering from a school of applied science of recognized standing; at least 7 years of experience in engineering design, estimate, and construction work, 4 years of which shall have been in responsible charge of such work; wide knowledge of public works construction and maintenance work and ability to manage and supervise engineering works of considerable importance.
5. District Engineer (grade 2), $4,000. Education equivalent to graduation in engineering from a school of applied science of recognized standing; 5 years of experience in engineering estimate, survey and construction work, 2 years of which shall have been in responsible charge of such work; preferably thorough knowledge of local conditions and works; firmness, tact, good judgment and ability to manage men.
6. District Engineer (grade 1), $3,500. Same qualifications as for District Engineer (grade 2).
7. Dredging Engineer, $3,500. Education equivalent to graduation in engineering from a school of applied science of recognized standing; at least 5 years of experience in engineering survey, consrtuction, dredging, and maintenance of a dredging fleet, 3 years of which shall have been in responsible charge of such work; thorough knowledge of dredging operations; firmness, tact and ability to manage men.
8. Engineer Ottawa River Storage, $3,300. Education equivalent to graduation in engineering from a school of applied science of recognized standing; at least 5 years of experience in engineering survey, construction, and maintenance, 3 years of which shall have been in responsible charge of such work; thorough knowledge of river regulation works; firmness, tact, good judgment and ability to manage men.
9. Senior Assistant Engineer, $3,200. Education equivalent to high school graduation; either graduation in engineering from a school of applied science of recognized standing, with 3 years of experience in engineering design, estimate, and construction work, 2 years of which shall have been in a position of professional responsibility; or 5 years of practical experience in engineering design, estimate, and construction work, 2 years of which shall have been in a position of professional responsibility; firmness, tact, good judgment, and ability to manage men.
10. Resident Engineer, $3,140. Education equivalent to high school graduation; either graduation in engineering from a school of applied science of recognized standing with 3 years of experience in engineering design, estimate, and construction work, 2 years of which shall have been in a position of professional responsibility; or 5 years of practical experience in engineering design, estimate, and construction work, 2 years of which shall have been in a position of professional responsibility; thorough knowledge of railway and harbor works; tact, good judgment, and ability to manage men.
11. Chief Draughtsman, $2,500. Education equivalent to high school graduation; either graduation in engineering from a school of applied science of recognized standing with 4 years of experience in an engineering draughting office, 3 years of which shall have been in responsible charge of such work, or 6 years of experience in an engineering draughting office, 3 years of which shall have been in responsible charge of such work; ability to visualize proposed engineering works; familiarity with various types of structures which will best serve local needs; firmness, tact and ability to manage men.
12. Assistant Engineer, $2,100. Education equivalent to high school graduation; either graduation in engineering from a school of applied science of recognized standing with 3 years of engineering experience, 1 year of which shall have been in a position of professional responsibility; or 5 years of engineering experience, 1 year of which shall have been in a position of professional responsibility; firmness, tact and ability to manage men.
13. Chief Inspector, $2,100. Education equivalent to graduation in engineering from a university of recognized standing; at least 4 years of supervisory experience in general construction work; supervisory ability, integrity, tact and good judgment, good physical condition.
14. Junior Engineer, $1,800. Education equivalent to high school graduation; either graduation in engineering from a school of applied science of recognized standing with 2 years of engineering experience, or 4 years of engineering experience in design, estimate, construction, and maintenance work.
15. Inspector, $1,800. Education equivalent to high school graduation; at least 2 years of experience in building construction work; ability to read and interpret blue prints and to judge concrete mixtures; supervisory ability, integrity.
16. Instrument Man, $1,800. Education equivalent to high school graduation, attendance for 2 years at a school of applied science of recognized standing, or passing of the preliminary Dominion Land Surveyors' examination with 1 year of experience as Rodman or Junior Instrument Man, or 3 years of experience in a survey party as Rodman or Junior Instrument Man; thorough knowledge of the transit and level and ability to make all adjustments to either instrument.
17. Draughtsman, $1,500. Education equivalent to high school graduation; either attendance for 2 years at a school of applied science of recognized standing with 1 year of subsequent experience in a draughting office, or 3 years of experience in a draughting office; ability to make neat, accurate, and complete plans and drawings from notes or sketches.
18. Junior Instrument Man, $1,500. Education equivalent to high school graduation; either a course of 1 year in engineering in a school of applied science of recognized standing with the passing of the preliminary provincial or Dominion Land Surveyors' examination, and 1 year of training with a survey party, or 2 years of training with a survey party.
19. Engineering Helper, $1,200. Preferably primary school education; willingness and energy; in some cases a good sense of direction and locations and ability to handle a boat or canoe; good physical condition.

[NOTE.—For typographical convenience, minor changes in the form of the schedules have been made in their presentation above, particularly in the numbering and lettering ahead of the titles and in the repetition or omission of portions of titles, but we believe that these changes are not material, and that they do not in any way alter the exact meanings expressed and implied in the original form of the schedules.—EDITOR.]

It is rumoured in Kingston, Ont., that Prof. Clark will be appointed dean of the School of Science, Queen's University, succeeding Dean Goodwin, who has retired.

With the nationalization of the Grand Trunk lines almost an accomplished fact, an agitation has begun for the purchase by the Dominion government of the Edmonton, Dunvegan & Peace River Railway. This line was constructed by J. D. McArthur, and its bonds were guaranteed by the province of Alberta. The owners of the road are said to be unable to carry it on and the settlers in the Peace river valley are complaining of poor service. The provincial government is unwilling to take over or operate the road.

Joint Town-Planning Conference at Ottawa

American City Planning Institute and Town-Planning Institute of Canada Discuss Zoning, Cost of Public Utilities and Street Improvements, Proper Widths for Streets and Other Fundamental Considerations of City and Town Planning

WITH the co-operation of the Commission of Conservation of Canada, a joint conference of the Town Planning Institute of Canada and the American City Planning Institute was held last Friday and Saturday at the Chateau Laurier, Ottawa, Ont.

The conference opened at 2 p.m. Friday. The sessions Friday afternoon, Friday evening and Saturday morning were arranged by the American City Planning Institute. The Saturday evening session was arranged by the Town Planning Institute of Canada. Saturday afternoon was reserved for drives and a visit to the Parliament Building.

After addresses of welcome by Hon. N. W. Rowell, president of the Privy Council, and Mayor Fisher, of Ottawa, reports were submitted by F. L. Olmsted (see next column) and B. A. Haldeman (see page 409 of this issue).

E. H. Bassett's report (see page 410 of this issue) was the chief topic for discussion on Friday evening.

The Saturday morning session was devoted to discussion of A. C. Comey's report, which will appear in the next issue of *The Canadian Engineer*, and Morris Knowles' report (see page 404 of this issue).

Address by Ottawa Planners

At noon Saturday the members were the guests at luncheon of the Canadian Club of Ottawa, and in the evening they were the guests at dinner of the Commission of Conservation and the city council of Ottawa.

Addresses by Thos. Adams and Noulan Cauchon, both of Ottawa, were the features of the final session, Saturday evening.

There was a very representative attendance of some of the leading town planners of Canada and the United States and all were enthusiastic regarding the benefits that will ensue as a result of this international conference.

In the addresses of welcome by Hon. Mr. Rowell and Mayor Fisher, both speakers laid stress on the advantages of international conferences of this nature, especially in the newer centres where development is rapid and the opportunity is great for housing more nearly approaching the ideal.

The committee reports relating to fundamental town planning principles, which comprised the greater portion of the program, were concise statements of about 1,000 words each, but the chairman of each committee elaborated upon his report when reading it.

While meeting in the main with the approval of the conference, these reports were not definitely adopted by the American City Planning Institute and are to be further considered.

Interesting discussion followed each report, especially in regard to the exact definition of terms used. To decide what the term "city planning" includes, and whether some other term might be preferable, was one of the matters left to a joint committee of the two institutes.

Zoning in Canadian Acts

In regarding to zoning it was pointed out that in Canada most of the provinces have in force town planning acts which incidentally provide for zoning amongst other features dealing with the amenities of the areas affected.

At the Canadian Club luncheon there were not only the members of the American and Canadian planning institutes, but also many other engineers. Dean Mitchell, of the Faculty of Applied Science and Engineering, University of Toronto, who was the speaker and guest of honor, discussed the aesthetics of the war and the lessons to be drawn therefrom. He announced that civics and town planning are to be included in the science courses at the University of Toronto.

One of the features of the conference that aroused very favorable comment was the exhibit of housing and town planning schemes and data. The exhibit was entirely of Canadian material and was supplied by the office of the Dominion Housing and Town Planning Adviser and other federal and provincial government offices, individual Canadian engineeers and architects also having made contributions to the exhibit.

The importance of housing was frequently referred to throughout the conference. In his address of welcome, Hon. Mr. Rowell described housing conditions and the environment in which thousands are compelled to live in the larger cities of the American continent, as the great crime of the past. He urged the members to strive during the present reconstruction period to bring about a new and better social order.

The members of the institutes visited the sites of two housing projects of the Ottawa Housing Commission, and at "Lindenlea," Thomas Adams explained briefly the salient features of that project.

The progress of housing in the United States and in some of the provinces of Canada was commented upon by various authorities conversant with the subject, and last Saturday evening Thos. Adams showed moving pictures of housing projects carried out in England and Canada.

"The Planning of Ottawa" was treated by Noulan Cauchon, chairman of the Ottawa Branch of the Town Planning Institute of Canada, in a broad and entertaining manner. Mr. Cauchon's address ended what was unanimously declared to have been a very successful conference.

Following are the committee reports presented by Messrs. Olmsted, Knowles, Haldeman and Bassett:—

FUNDAMENTAL CONSIDERATIONS OF CITY PLANNING

By F. L. Olmsted

Chief Town Planner for the U. S. Department of Labor

THE purpose of this statement is to set forth certain fundamental considerations of city planning as an explanatory introduction to any specific conclusions which the American City Planning Institute may see fit to adopt in relation to special and limited questions within its field; largely to avoid the danger that such specific conclusions standing alone might give a mistaken impression of the scope of the subject and the attitude of the institute.

City planning, which in this statement is used broadly to cover the entire subject-matter, designated also by such terms as town planning and regional planning, is concerned with the territory occupied or to be occupied by any community and with prospective physical alterations in that territory and the objects upon it, in so far as such alterations can wisely be controlled or influenced by concerted action in the interest of the community as a social unit.

In theory no prospective physical alteration is so small, so localized, or so specialized in technique as to be excluded merely for that reason from the scope of city planning, provided it can wisely and effectively be controlled in the common interest. A problem of city planning may be wholly within the field of one of the many well-established specialized technical professions having to do with the physical surroundings of community life, or may concern several such fields, or may lie in a sort of no man's land, inadequately covered by any one of these professions.

The field is so wide and so complex that on the one hand effective progress in mastering it requires specializa-

tion, and makes it inevitable that much of the progress in technical knowledge and skill on which successful city planning depends will arise from the activities of innumerable specialized organizations, most of which concern themselves little with city planning as a whole, and that on the other hand it is necessary for any organization which deliberately addresses itself to city planning as a whole to concentrate as far as possible upon those aspects of the field which cannot be, or are not, effectively dealt with upon any narrower basis.

In theory there are no limitations to the extent of co-ordination desirable among the diverse planning activities which shape the physical growth of a community or to the extent to which it is desirable to estimate future contingencies and take account of them in planning; but practically there are very decided limitations upon the amount of time and effort which can be withdrawn from the vital business of getting things done for the sake of study and planning what to do and how best to do it.

The Most Fundamental Consideration

The most fundamental consideration of all in city planning, therefore, is to apply sound, clear penetrating common sense to the problem of how far it will pay to go, under any conditions, in forecasting the future and adapting present plans to future contingencies, and in suspending plans for meeting definite limited objectives of a local or specialized sort and modifying them for the sake of community purposes with which they are not directly concerned.

The classes in specific city planning problems which are most distinctively matters of city planning are:—

(a) Those in which the permanent interests of a community justify the modification of plans so as not merely to secure the immediate objects of a contemplated improvement, but also to fit the probable contingencies of a remoter future or to fit community needs which are only indirectly connected with the objects immediately in view.

(b) Those in which a close co-ordination of planning in two or more fields of technical work ordinarily segregated from each other in practice is likely, through avoidance of conflict and fuller utilization of joint opportunities, to secure advantages commensurate with the effort of obtaining the necessary co-ordination.

(c) Those which lie so much outside of the fields which are effectively covered by any specialized planning agencies that the community is likely to suffer from their neglect.

Merely to recognize problems of the above classes as they arise in the routine of community growth and to consider them from the broad standpoint of the community's general interests is city planning in a conservative or defensive sense. But constructive city planning requires also that many such problems, long before they become acute, shall be anticipated and considered under the impulse of imagination applied toward the attainment of the larger social objectives of the community.

Limited in Three Ways

Any one discussion of city planning must be limited in one or more of these ways: (1) It may be general and superficial; or (2) it may be confined to the problems of planning a limited area in a more or less complete and co-ordinated way, as for example, the planning of a residential subdivision, or of an industrial terminal district; or (3) it may deal with a limited class of problems in wider application as considered from the city planning standpoint, as for example, the planning of main thoroughfares or the distribution of schools and playgronds.

Almost any limited subject of discussion in city planning might be, so far as mere title is concerned, as appropriate for discussion in some other technical society as in the City Planning Institute, but such subjects will be discussed here always in their bearing on all the rest of city planning rather than in their bearing on the rest of highway engineering or of the educational system or other special technical field in which they happen to fall.

COST OF UTILITIES AND STREET IMPROVEMENTS AS AFFECTED BY THE SIZE OF RESIDENCE LOTS

By Morris Knowles
Consulting Engineer, Pittsburgh, Pa., and Windsor, Ont.

AT the outset it should be understood that there are other factors affecting the size at which lots should be designed, in addition to street improvements and utilities. It will be advantageous therefore to present a brief statement of these other various factors, in order that phases which are considered in this paper may be co-ordinated with them. Such factors are:—

1. Cost of land.
2. Size and arrangement of rooms in house.
3. Certain improvements that lie within the boundaries of the lot, such as grading (which is affected by topography), planting, fences, hedges and house walks.
4. Desirability of a front yard to properly set off house and to establish privacy from passers on street.
5. Desirability of a side yard to ensure sunshine, proper ventilation, adequate fire protection and suitable approach to rear.
6. Desirability of a rear yard to provide space for clothes line, house garden, garage perhaps, and playground for the children.

Elements Not Related

There are elements, even of street improvements and utilities, that in no way are related to size of lot. For example:—

(a) Those divisions of utilities that lie outside townsite boundaries, as water supply plant, both pumping station and filtration units; sewage treatment and disposal plants; power plant to generate electricity; steam plant, in event houses are to be heated from a central heating station; and in some cases a gas plant, though it may be doubtful whether such a plant would be erected.

(b) Various trunk supply lines which lead from the respective supply plants to townsite. These include water supply trunk line; gas and steam trunk lines; electrical transmission line; and sewer outfall line.

(c) There are certain portions of street improvements and utilities lying even within boundaries of townsite which are not directly and immediately affected by size of lot. For example, those street improvements and utilities that lie directly in front of house and that parallel the depth of house. These portions of utilities and street improvements are more affected by size and arrangement of house than by dimensions of lot. Likewise, there are certain elements of house connections which are not affected by size of lot; for example, conections to mains, curb-boxes, stop cocks, meters and the portions of house services that lie within the street.

The foregoing elements bear an important relation to the cost of utilities, in so far as they affect cost per capita or cost per house, but they are not in any way related to size of lot.

A well defined statement regarding those portions of utilities and street improvements which directly relate to size of lots can now be made.

(a) They include street improvements and utilities located directly in front of the space lying between houses.

(b) Street improvements and utilities located on minor streets that lie parallel to space occupied by front yards and by rear yards.

(c) Lengths of house service connections which are located in front yards and in rear yards.

Assumed Townsite

In order to estimate relative costs, it will be necessary to assume a town layout. Following are the factors:—

An industrial town with 1,000 houses. Houses are 22 ft. wide and 30 ft. deep. Lots are 42 ft. front by 80 ft. deep. Houses are located on center line of lots and are placed 15 ft. back from front property line. Main streets are 50 ft. wide; minor streets 40 ft. wide. Main streets have 24-ft.

(Concluded on page 409)

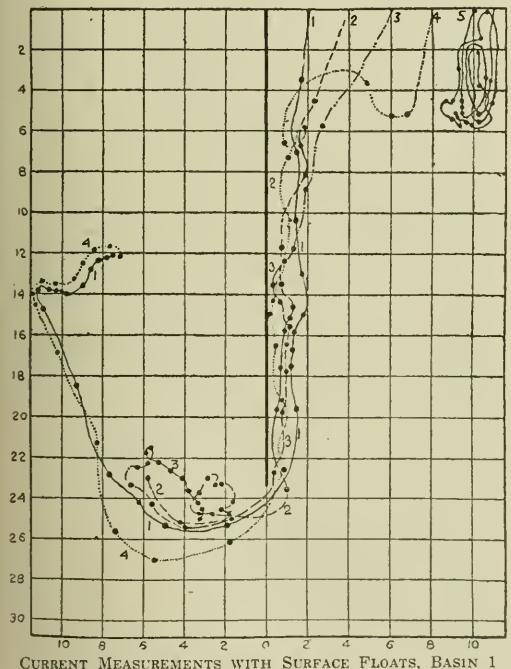
SOME OBSERVATIONS AND EXPERIENCES IN THE OPERATION OF COAGULATING BASINS*

By James Wadsworth Armstrong
Filtration Engineer, Water Works Department, Baltimore, Md.

THE two coagulating basins of the Montebello filters of the Baltimore water works are each 317 feet long, 232 feet wide and have an average depth of water of about 15 feet. A central baffle wall extends about three-quarters of the length of each basin. Water is admitted through five sluice gates, spaced at equal intervals, and, after passing around the baffle, is withdrawn through a similar number of gates. The water passes over a baffle at the entrance and over a skimming weir at the exit. It was the hope of the designer that the water would move with reasonable uniformity through the basins, but this has not been realized.

In the course of operation it was noticed that the movement of water through each of the two coagulating basins was different, although they were operated in parallel and apparently under the same conditions. It was also noticed that the water, while following characteristic lines in each basin, seemed to vary from time to time.

In order to learn something more definite regarding the exact movement of the water and its effect on the efficiency of the basins, a series of sixteen different current measurements was made. For making the observation, six identical

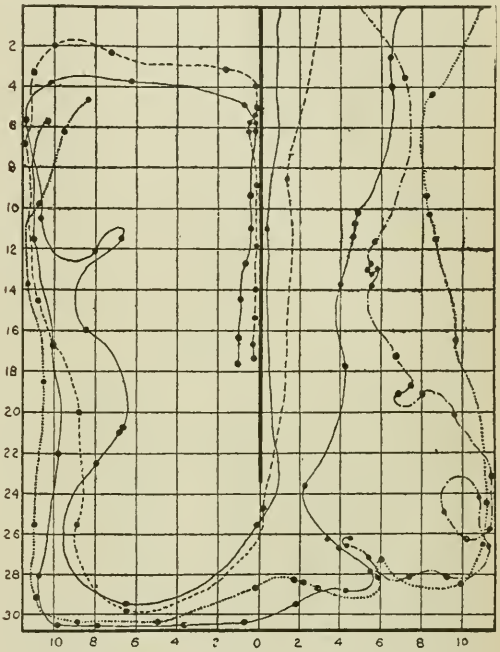


Current Measurements with Surface Floats, Basin 1

Readings of floats taken every five minutes; Venturi rate of flow, 123 m.g.d.; August 21st, 1917.

aluminum floats were used. Each float was cross-shaped in plan, and was composed of four sheets of aluminum, each 6 by 12 ins., inserted in a pine strip. The floats were just heavy enough to half submerge a large cork, to which a number was pinned. The portions of the floats exposed to the wind were very small, and, as the observations were not made on windy days, it is believed that their movements indicate the currents through the basin with reasonable accuracy. Most of the observations were made with the floats submerged just below the surface or 4 ft. below.

The floats were started at the entrance of the basin, and readings were taken, locating their position, every six minutes. The floats in the main channel, both surface and at the 4-ft. depth, generally moved forward at relatively high velocities, while those along the outer edges of the basin



Current Measurements with Surface Floats, Basin 2

Readings of floats taken every five minutes except first reading on each float, which had six minutes interval; Venturi rate of flow, 128 m.g.d.; August 14, 1917

moved in very erratic ways, sometimes getting caught in eddies in the corners and staying there for hours. Basin 1 usually showed an eddy at the entrance in the north-west corner, probably due in part to a slight difference in the alignment of the baffle. Basin 2 showed no eddies at the entrance, but both basins showed eddies in the far corners and usually along the outlet side of the baffle wall.

On August 14th, 1917, surface floats were used for making current measurements in Basin 1. The velocity of the floats varied considerably. Some of them moved *forward* at rates as high as 32 ft. per minute. On the outlet side of the baffle, two of them were carried *backward*, adjacent to the baffle, for three-quarters of its length. On August 18th, 1917, the basin was cleaned, and on August 21st other surface float measurements were made. On this occasion the floats moved along entirely different lines. One of them circled around in the north-west corner, the other four moved slowly along the baffle wall at velocities of from 2 to 12 ft. per minute, and on the outlet side of the baffle showed no decided forward movement.

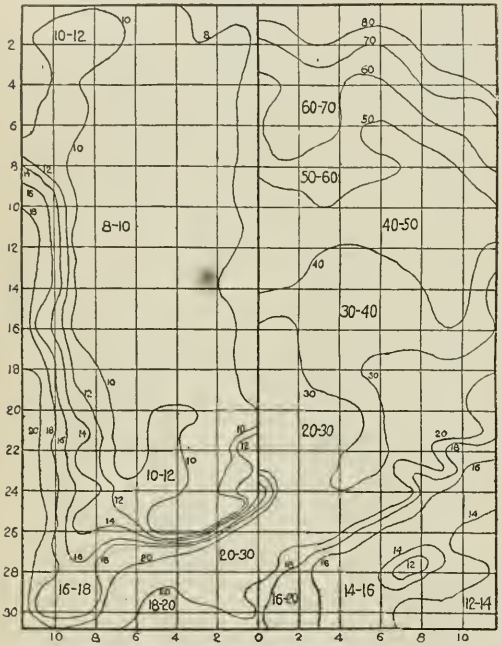
The greater velocity and more uniform movement of floats on August 14th was due to the fact that mud had filled the lower part of the basin, necessitating higher surface velocities. Most of the float measurements showed that higher velocities were obtained near the baffle wall on the incoming side and the outer wall on the outgoing side. A survey of the mud surface just before cleaning showed that the heaviest

*Paper presented to the American Water Works Association.

deposits followed approximately the lines of maximum velocity of flow, and that the greatest depth of deposit was at a point a little over 50 ft. from the entrance. The corners where eddies occurred had the least depth of mud.

On August 16th, 1917, two days before cleaning the basin, a turbidity survey of Basin 1 was made. Readings were taken at intervals of 10 ft. with a United States Geological Survey turbidity rod. The heaviest turbidities were observed at the entrance, and from there they decreased along pretty well defined but irregular lines toward the rear of the first half of the basin. In the second half of the basin the maximum turbidities followed approximately the lines of greatest velocity. This test seemed to indicate that the velocity at the entrance was too high to secure the best subsiding value, and that uniform velocities are necessary for uniform subsidence.

At one time, for a short period only, the bacterial counts were slightly higher in the effluent from the coagulating



Surface Turbidity Measurements, Basin 1

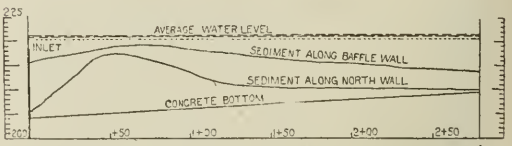
Readings taken with U. S. G. S. turbidity rod; Venturi rate of flow, 115 m.g.d.; August 16th, 1917

basins than in the raw water. The increase of growth in the basins led to the belief that bacteria were multiplying in the places where the currents were sluggish and were being gradually swept into the main current and carried to the filters.

In order to test the accuracy of this theory, several careful bacterial surveys were made. Numerous samples were taken at points showing the greatest difference of turbidity and velocity. One set was taken near the surface and another at a depth slightly above the mud line. The samples taken near the entrance of the basin showed slightly higher counts than those taken at other places, but none of the results showed any evidence of increased growth in any part of the basin.

In addition to the variations in velocity and the lack of uniformity in mud deposits, other irregularities were noticed in the functioning of the basins. As an illustration, it was noted on one occasion that Basin 1 gave decidedly better results than Basin 2, but upon making a slight change in the opening of one of the inlet gates, the condition was shortly reversed and Basin 2 gave markedly better results than Basin 1.

This phenomenon raised the question as to the possible effect of undercurrents upon the subsiding value of the basins. It was argued that if the elements of water in moving through the basin could be kept in nearly parallel



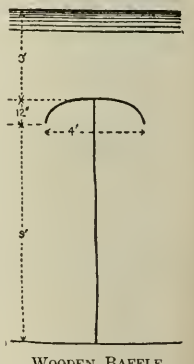
Sediment in Basin 1 on May 25th, 1916

lines, and if the movement could be confined to the surface of the water, leaving the lower stratum undisturbed, much greater subsiding value could be obtained.

With the purposes of testing out this theory, some modifications were made in the existing entrance baffle, and an additional cross-baffle was built in Basin 1. In order to give a positive outward sweep to the water entering the basin, increase the surface velocity and prevent returning undercurrents, a wooden apron about 2 ft. wide and sloping in an upward direction, was attached to the top of the existing entrance baffle. At the end of the existing concrete baffle, about 240 ft. from the entrance, an additional wooden baffle was built entirely across the basin. No changes were made at the outlet skimming weir. The new baffle was 10 ft. high and was capped with a top 4 ft. wide, which projected 2 ft. on each side. The top was curved downward at the ends in the form of a parabola. Water usually flowed about 3 ft. deep over the top of the baffle.

The following reasoning was responsible for the building of the unusual type of cross-baffle:—

The reduction of the cross-sectional area would tend to establish a more uniform flow across the top of the basin and create a quiet zone near the bottom that would permit better sedimentation. It was well known that when flowing water meets an obstruction, such as a baffle, there is a decided tendency to pick up sediment and carry it over the top, and it was argued from the known characteristic of a parabola to reflect rays of light in parallel lines that the sediment in the rising currents of water would, upon striking the parabola, be thrown downward and deposited, instead of being carried over into the next compartment. The curved top over the rear of the baffle is only useful in gradually reducing the velocity of water flowing over the top.



Wooden Baffle Across Basin 1

After this baffle had been in service for a number of months, the basin was cleaned. It was found that the apron extending across the top of the baffle at the entrance of the basin had been built a little too near the surface, and the velocity of entering water was so great that it carried most of the sediment outward as far as the cross-baffle. The results at the cross-baffle, however, were most gratifying. The parabolic top had evidently acted exactly as had been anticipated, for the mud was deposited adjacent to the baffle, almost to its full height, and sloped gradually backward to the entrance of the basin. The baffle on the return side had not performed so well, probably owing to the fact that the water in passing over it was not flowing in a direction normal to its face. It is believed that if this baffle had been placed about 70 ft. nearer the outlet it would have worked better.

As soon as the opportunity is afforded, the apron controlling the incoming water will be lowered so as to decrease the velocity at the entrance, and the baffle on the outgoing side will be removed forward. It is hoped that then the sediment will be deposited more uniformly.

This hopeful but imperfect experiment is made public with the thought that it may stimulate others to make further experiments or lead them to publish information which they already have.

COUNCIL OF THE ENGINEERING INSTITUTE SUPPORTS BILL CLASSIFYING CIVIL SERVICE

IT has been decided by the council of the Engineering Institute of Canada that it is advisable to support the bill, now before the Dominion parliament, relating to the reclassification of the civil service of Canada, at least to the extent that this bill affects the engineering profession.

This decision was reached despite considerable dissatisfaction with the proposed classifications and remunerations. It was feared that any concerted opposition to the bill would mean that it would not be passed in any form at all this session, and possibly not for many years.

Recommendations have been made to the Civil Service Commission by the deputy ministers of the various departments, and those recommendations have been taken into consideration, and many changes will be made in the bill as a result. Although it is not clear that the recommendations will be accepted in full, the necessary machinery has been provided for dealing with individual cases. An advisory board to the Civil Service Commission has been appointed, and it is understood that a board of appeal will be constituted, so that any decision of the Civil Service Commission (acting on the advice of the advisory board or upon representation made by a deputy) regarding any classification, may be appealed and reconsidered.

The proposed bill elevates the engineers employed by the government, giving them a certain status which they never previously had, and also in the majority of cases grants increased remuneration, and for these reasons it is now urged by the council of the Engineering Institute that the proposed bill be supported by engineers throughout Canada.

LIGNITE BRIQUETTES NEXT AUGUST

FINAL decision as to the location of the plant to manufacture briquettes from the lignite deposits in south-eastern Saskatchewan and south-western Manitoba will be made in the immediate future, states R. A. Ross, chairman of the lignite utilization board, which held its first session in western Canada two weeks ago in the Manitoba legislative chamber at Winnipeg.

Mr. Ross stated that the board would visit the lignite deposits and would discuss the matter of the location of the $400,000 plant. He said that it is the intention of the board to let all contracts for the construction and equipment of the plant during the coming winter, construction to commence as soon as possible, and if the plans of the board do not miscarry, the plant will be producing briquettes by August, 1920. The capacity of the plant will be 30,000 tons a year and briquettes will be sold to the coal dealers in Winnipeg at approximately $9.40 a ton.

The briquettes will be made from coal supplied by the mines now operating in the district and the board will probably pay $1 a ton for this very poor grade of lignite. If the lignite is not available from the mines, the board will undertake mining operations.

When asked by Hon. T. H. Johnson how the board would fill the demand for briquettes if the demand is in excess of the supply, Mr. Ross replied that that is a political question. Mr. Johnson afterwards explained that the point upon which he was seeking information is whether the board will make a fair distribution of the product, under such conditions, between Manitoba and Saskatchewan.

PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSING OF TURBINE GATES*

By Ford Kurtz
Muscle Shoals, Ala.

MR. GIBSON has made a valuable addition to the too few and scanty English treatises on the mathematical theory of water-hammer. His treatment of the subject, however, is chiefly of value in obtaining, without the use of differential equations and from physical laws the import of which is readily grasped, formulas which give the same practical results as the much simpler and less cumbersome equations of Lorenzo Alliévi, first published in Rome, in 1903. These equations must not be confused with the confessedly approximate and inadequate formula designated by Mr. Gibson as the "Alliévi formula," and on which R. D. Johnson has apparently founded a pressure-time equation. The equations referred to are mathematically rigid formulas which take into account not only the effect of net head but also the compressibility of the water and the extensibility of the pipe and which, so far as the writer knows, have never before been published in English. In 1911, the writer prepared, for his own use, a translation of a German translation of Mr. Alliévi's work, and found the latter's treatment so remarkably comprehensive and thorough that he has used it ever since in all water-hammer problems. The German translation† can be found in the Engineering Societies Library.

In presenting the exact formulas of Alliévi, the following nomenclature will be added to that of Mr. Gibson's paper:

$R_0 = aV_0/g$ = excess, or water-hammer, head due to instantaneous complete closure of gate.

$m = aV_0/gH_0$ = ratio of instantaneous water-hammer head to net head.

$F(t)$ and $f(t)$, or simply F and f = certain functions of time, t.

$z = (H_0+h_t)/H_0$ = ratio of total variable head to net head.

$\phi(t)$ = gate-opening at time, t, as a ratio of maximum gate-opening.

The exact formulas of Alliévi contain a term which makes it possible to determine the pressure at any point of the pipe line at any moment, but the writer is presenting only the simple form for determining pressure at the outlet,

*Discussion (presented to the American Society of Civil Engineers) of Norman R. Gibson's paper (see September 4th and 11th issues of *The Canadian Engineer*).

†"Allgemeine Theorie über die veränderliche Bewegung des Wassers in Leitungen," von Lorenzo Alliévi, 1909.

or discharge section just up stream from the gate, as that is the problem investigated by Mr. Gibson. It is also assumed that the pipe line is of uniform thickness and diameter throughout its length. Then, during the period,

$$0 < t \leq 2L/a,$$
$$z = 1 + F(t)/H_0,$$

where

$$F(t)/H_0 = m + \tfrac{1}{2}m^2[\phi(t)]^2 - m\phi(t)\{1 + m + \tfrac{1}{4}m^2[\phi(t)]^2\}^{1/2}.$$

and, during the period,

$$2L/a < t \leq T,$$
$$z = 1 + F(t)/H_0 - F(t - 2L/a)/H_0 = 1 + F(t)/H_0 - f(t)/H_0,$$

where

$$F(t)/H_0 = m - f(t)/H_0 + \tfrac{1}{2}m^2[\phi(t)]^2 - m\phi(t)\{1 + m - 2f(t)/H_0 + \tfrac{1}{4}m^2[\phi(t)]^2\}^{1/2}.$$

For the linear law of gate movement, $\phi(t) = 1 - t/T$, as already stated by Mr. Gibson.

These formulas applied to Mr. Gibson's first example give the following equations:—

For $0 < t \leq 0.35$ sec.,

$$F(t)/H_0 = 10.35008 + 53.56185\phi^2 - 10.35008\,(11.35008\phi^2 + 26.78092\phi^4)^{1/2}$$

and, for $0.35 < t \leq 6.0$ sec.,

$$F(t)/H_0 = 10.35008 - f(t)/H_0 + 53.56185\phi^2 - 10.35008\{[11.35008 - 2f(t)/H_0]\phi^2 + 26.78092\phi^4\}^{1/2}.$$

As already noted by Mr. Gibson, the values of $F(t)/H_0$ and $f(t)/H_0$ are so small compared with some of the individual terms of the equations, that it is necessary to use logarithms in solving the equations.

Using the exact Alliévi equations as given previously, Table 1 has been prepared, showing the rise of pressure and also the differences between the values of the rise obtained by Alliévi equations and those obtained by Mr. Gibson's equations. The maximum divergence of less than one-half of 1% shows the remarkable agreement of the two methods. It is apparent, however, that the simplicity of the solution by the Alliévi formulas, without giving heed to magnitude and direction of waves in the computations, makes it far superior to that of Mr. Gibson as a working method.

The exact formulas of Alliévi also furnish equations similar to those given previously for the case of the opening of a valve at the lower end of a pipe line, either from fully closed position, or from some initial partial opening. As already stated, in their complete form they also give the pressure at any time for any point along the pipe line, thus covering the matter mentioned by Mr. Gibson as to be discussed by O. V. Kruse.* Of course, there are also exact equations for the velocity at any time for any point along the pipe line.

The partial differential equations for the general motion of water in pipes are based on the fundamental differential formulas for the motion of water in general. Unfortunately, these partial differential equations, four in number, cannot be integrated (not even by approximate arithmetic integration so far as the writer knows) without making the following simplifying approximations:—

1. Velocity in direction of axis of pipe considered uniform over any chosen section of the stream.
2. Skin friction and viscosity neglected.
3. Velocities at right angles to the axis of the pipe, due to expansion or contraction of the pipe by changes in pressure, neglected.
4. Pressure considered uniform over any chosen section of the stream.
5. Assumed that the pipe consists of individual circular elements independent of each other, which are freely extensible.
6. Assumed that the ratio of velocity of water in the pipe to the velocity of propagation of pressure changes is small enough, compared with unity, so that its addition thereto or subtraction therefrom can be neglected in every case at every instant.

By making these approximations, we obtain the so-called exact formulas of Alliévi.

*See *The Canadian Engineer*, October 9th, 1919, p. 370.

Mr. Gibson's method of taking account of skin friction (which is only approximate, as has been pointed out by William P. Creager), could easily be applied to the exact Alliévi formulas by changing the factor m so as to have it correspond at all times to $(H_0 + ht)$ instead of to H_0.

The exact Alliévi formulas can be applied so as to take account of varying diameters and thicknesses of pipe in the same line, but they soon lead to so much complication that they become impracticable. In such cases, the writer uses the formulas as already given for a pipe of uniform diameter and thickness, but gives to m the value, $Q_0\Sigma(L/A)/gH_0\Sigma(L/a)$, where Q_0 equals the flow of water in a pipe at full gate-opening, L equals the length of any section of pipe, A, its cross-sectional area, and a, its individual value of the velocity of propagation of pressure changes. Also the factor, $2L/a$, must everywhere be changed to read $2\Sigma(L/a)$. This is confessedly an approximation made without mathematical proof, but it is probably exact enough for practical purposes in the majority of problems.

U. S. WATER POWER LEGISLATION

EFFORTS are being made by the engineers of the United States to obtain some measure of improvement in the water power legislation of that country. A circular letter has been drafted by the Water Conservation Committee of the U.S. Engineering Council and is being sent to every U.S. senator. The letter, which was signed by Alfred D. Flinn, secretary of the U.S. Engineering Council, is as follows:—

"Engineering Council asks your consideration of H.R. 3184, 66th Congress, 1st Session, which provides for the development of water powers in the navigable streams and on the public lands in the United States. This bill has passed the House of Representatives and is now before the Senate.

"During the past ten years, water power development in the United States on the public lands and in the navigable streams has languished. A certain small amount of development has taken place under conditions over which the Federal Government has no authority, but the best and most feasible development sites require Federal consent. Bills suitably providing for such consent have been under debate for a decade and the one above referred to (H.R. 3184) is approved by the heads of the several Federal departments concerned and also by the President. Advocates of legislation who have been on opposite sides of the water power question are generally agreed as to the merits of this bill and it is believed that it is the best measure that has yet been before Congress with any chance of passage. Probably, those who are now in disagreement after ten years of study and debate would be in the same position ten years hence. Therefore, it is bad public policy to wait longer; also, detrimental to the public interest and to industrial development.

"The importance of water power development in stimulating all kinds of industry, especially manufacturing, and the vital necessity of conserving and economizing our fuel supply, which, in turn, would largely relieve our congested transportation facilities, are so generally recognized that they need not be here emphasized.

"We, as engineers, are aware that the penalties that the country has already suffered by reason of the embargo on water power development, and would suffer from the consequences of further delay, are greater than those which could possibly be produced by all of the defects claimed against the bill by its few remaining opponents.

"We therefore hope you will lend your influence in favor of the speedy passage of the pending measure."

One can obtain a good conception of the remarkable growth of the American Association of Engineers during the last year when it is known that the number of paid employees at the national headquarters has grown in that time from four to sixty.

COST OF UTILITIES AND STREET IMPROVEMENTS

(Continued from page 404)

paved roadway, 5½-ft. planting strips, combined concrete gutters and curbs, and 5-ft. sidewalks. Alleys are omitted. There are 24 houses in each block, making length of block 504 ft. and width 160 ft. There are approximately 42 such blocks in the townsite. Filtration plant and pumping station is assumed, two miles from townsite; sewage disposal plant, one mile away; and electric transmission line and gas trunk line each three miles long. Assumed that it will not be necessary to build electric plant or gas plant.

TABLE 1—ESTIMATE OF ASSUMED TOWNSITE

Item	Cost Per House	Percent of Total Cost	Including Overhead
House	$3,000.00	54.85	64.0
Land	336.00	6.14	7.2
Lot improvements	232.64	4.25	4.9
Street improvements	463.29	8.48	9.9
Water system	190.15	3.48	4.1
Electrical system	26.33	0.48	.6
Gas system	101.18	1.85	2.1
Sewers—Storm and sanitary	202.48	3.70	4.3
House connections	138.50	2.53	2.9
	$4,690.57		
Engineering and supervision at 10%	469.06	8.58	
	$5,159.63		
Interest at 6%	309.58	5.66	
	$5,469.21	100.00	100.0

It will be noted house is 64% of total cost, including distribution of overhead; land with lot improvements, 12.1%; street improvements, 9.9%; water, electrical, gas and sewer improvements, with house connections, 14%. Engineering, supervision and interest charges, which are distributed in these statements, are 14.24% of the whole.

Figures shown in Table 2 are cost per lineal front foot of side yard and per lineal foot depth of front and rear yards. Costs per lineal foot lot frontage and depth would be greater, as cost of house meters, shut-off valves, etc., would be included in this cost.

TABLE 2—COST OF UTILITIES AND STREET IMPROVEMENTS PARALLEL TO YARD SPACE

	Cost for Length Parallel to 20-ft. Side Yard	Cost Per Lin. Front Foot of Side Yard	Cost for Length Parallel to 50-ft. Front and Rear Yard	Cost per Lin. Foot Depth of Front and Rear Yard
Street improvements	$178.60	$ 8.93	$ 55.00	$1.10
Water system	36.40	1.82	13.00	.26
Electrical system	4.20	.21	.00	.00
Gas system	17.40	.87	6.50	.13
Sewers — Storm and sanitary	54.00	2.70	17.00	.34
House connections	.00	.00	32.50	.65
	$290.60	$14.53	$124.00	$2.48

Results in Table 2 show that if space between houses on main streets is increased one foot, cost of utilities and street improvements per house is increased $14.53. If front or rear yard is increased one foot in depth, cost of street improvemnets and utilities per house is increased $2.48. These computations bring out the interest fact that in so far as street improvements and utilities are concerned, 5.86 ft. can be added to depth of front or rear yard for same cost of adding one foot to width of side yard.

Assuming for sake of comparison a lot 42 ft. front by 80 ft. deep, the combined cost of land and lot improvements is equal to $568.64, or $13.54 per front foot. (See Table 1). If, for this lot, costs of main and minor street improvements and utilities are combined and quoted as cost per lineal front foot of side yard parallel to yard space, they equal $20.73 per lineal foot.

If the cost of land and lot improvements be combined with cost of utilities and street improvements on main street parallel to side yard, the cost per lineal front foot of side yard is $28.07. Assuming rents based on 10% return, rent for each front foot of side yard is 23 cents per month, of which 12 cents is for street improvements and utilities, and 11 cents is for land and lot improvements. This is the cost of air and sunshine, or $4.60 per family per month.

While no sweeping conclusions can be made, because we have discussed only one assumed townsite, it is interesting to note that cost per lot for "street improvements and utilities" is $1,121.93, compared with $568.64 for "land and lot improvements," the latter being 50% of former. If however, we compare cost per front foot of those elements of street improvements and utilities directly related to size of lot, with cost per front foot of lot improvements and land, they are respectively $20.73 and $13.54, the latter being 65% of the former.

Some Suggestions

Following are some suggestions on economical design and construction:—

Use contour streets.

Grade lots and streets at same time.

Design street widths and pavements to meet demands of traffic.

Compare cost of reducing grades with cost of pavements suitable for steeper grades.

Do not make sidewalks unnecessarily wide.

Use combined gutter and curb.

Study relative merits of alleys and easements.

Study carefully location of utilities.

Use combined trenches where suitable.

Substitute direct sewer connections for catch basins.

Use combination manholes.

Connect roof leaders to gutters.

Omit storm sewers near summits of streets.

Install house connections at one time.

Carry house wire services on brackets attached to rear of house.

RULES OF PRACTICE FOR THE ESTABLISHMENT OF STREET WIDTHS AND THEIR SUBDIVISIONS

By B. A. Haldeman
Advisory Engineer, Zoning Commission, Philadelphia, Pa.

STREETS should be divided into the following four classes, based upon their immediate and future purpose and service: Main, secondary, minor and special service streets.

Main streets will form the principal routes for the immediate or future use of large volumes of mixed traffic moving between important centres within a community or from community to community.

Secondary streets will be those of lesser traffic importance, supplementing the main streets and serving to distribute mixed traffic to and from the latter and between centres of lesser importance.

Minor streets will be those laid out for purely local traffic use or to facilitate the subdivision or development of property.

Special service streets will be those designed and laid out for special purposes and restricted to special uses.

The General System

The location, width and subdivision, and also the grade, of main and secondary streets should be based upon their present and future value as traffic carriers. They will form the primary net of the street system and should be planned in advance of urban improvements as the controlling elements in the general development of the transportation and other circulatory facilities of the city and the adjacent region, and consideration should be had in their layout for the economic development of those facilities. At least a primary scheme of zoning for use should precede or accompany their layout.

Certain types of special service streets, particularly those designed to connect the units of a park system, should be laid out coincident with the traffic net.

With the net of main and secondary streets established, the areas lying between them may be subdivided by such system of minor or special service streets as may best serve the development of each particular area.

Street Widths

The width of a street shall be understood in all cases to mean the distance between the bounding property lines.

The width of main and secondary streets should be such as will adequately accommodate such classes and such volumes of traffic as are likely to be put upon them after the territory or region they serve shall be fully developed.

The width of minor streets should be such as will adequately care for local travel and service of abutting property.

As special service streets will be designed to serve special and particular uses, any attempt to standardize their widths would be futile.

Recommended widths are as follows:—

Main streets	108, 128 or 148 ft.
Secondary streets	60 or 80 ft.
Minor streets	12, 20, 40 or 50 ft.
Special service streets	Variable.

In cities and regions where the laying out of any considerable number of streets of a greater width than 80 ft. would be unwise, it is recommended that streets exceeding that width be placed in the special service class, the "secondary streets" classification eliminated, and the 60 and 80 ft. wide ones classed as "main streets."

Cross-Section Subdivisions

The unit width for a line of vehicles shall be 8 ft.

The unit width for a line of pedestrians shall be 2 ft.

The so-called "elastic" method should be employed in establishing and increasing the widths of subdivisions.

The roadway width of a street shall be the distance between curb lines, or between the centres of the gutters where there are no curbs.

No roadway for a single line of vehicles should be less than 8 ft. or more than 10 ft. wide.

Roadways to accommodate two lines of vehicles should be 20 ft. wide except that such roadways in minor and special service streets may be 16 or 18 ft. wide.

Roadways to accommodate three lines of vehicles should be 26 ft. wide.

Roadways to accommodate four lines of vehicles should be 36 ft. wide.

Any increase beyond a roadway width of 36 ft. should be made by adding an 8-ft. unit for each additional line of vehicles to be accommodated. Where the street is, or will be, occupied by street railway tracks, the unit should be undivided, but where there will be no tracks, the unit may be divided.

The minimum width of the space between the property line and the curb line, including width of the curb, should be as follows:—

On streets 40 ft. wide	11 ft.
On streets 50 or 60 ft. wide	12 ft.
On streets 80 ft. wide	14 ft.
On streets more than 80 ft. wide	18 ft.

Sidewalks and Planting Strips

The width of the paved footway on any street should not be less than 4 ft. Increases beyond that width should be by 2-ft. units or multiples thereof.

The planting strip between the property line and the nearest edge of the paved footway should not be less than 1 ft. wide on a 40-ft. wide street, or less than 2 ft. on a street of greater width.

The width of the planting strip between the curb line and the nearest edge of the paved footway, including the width of the curb, should in no event be less than 4 ft. in a street 60 ft. or less in width, or less than 6 ft., in a street of greater width than 60 ft.

Trees should be planted in such locations that they will not be disturbed by, or obstruct, any subsequent change in the curbs or paving.

Where dual roadways are laid, separated by a planting strip, the latter may be of variable width and the curbs adjacent to the sidewalk should be set in their permanent locations.

Where a central reservation for street railway tracks is established it should be at least 20 ft. wide.

The following are suggested typical widths and arrangements of cross-section subdivisions. (Figures indicate widths in feet):—

	40-ft. Streets.			50-ft. Streets.		
	(*a*)	(*b*)	(*c*)	(*a*)	(*b*)	(*c*)
Planting strip	1	1	1	2	2	2
Paved footway	4	6	4	4	4	6
Planting strip	6	4	5	9	6	4
Roadway	18	18	20	20	26	26
Planting strip	6	4	5	9	6	4
Paved footway	4	6	4	4	4	6
Planting strip	1	1	1	2	2	2
	40	40	40	50	50	50

	60-ft. Streets.			80-ft. Streets.		
	(*a*)	(*b*)	(*c*)	(*a*)	(*b*)	(*c*)

ZONING

By Edward M. Bassett
Chairman, Zoning Committee, New York City

THE subject should be called building zoning, the boards zoning boards or commissions. In laws and ordinances, the word "zoning" should be used in the title and the word "districts" in the body of the law to specify the areas affected. The word "zoning" is sufficient when city planning is under discussion.

Zoning is the creation by law of districts in which regulations differing in different districts prohibit injurious or unsuitable buildings and uses.

Zoning should be done under the police power of the state and not by condemnation.

Before attempting zoning, a city should obtain the power to do so from the state legislature. The essential statement in such donation of power is that the city may impose different regulations for buildings and for the uses of land and buildings in different districts.

Enhancement of value alone, or aesthetics alone, is not a proper basis for zoning when done under the police power.

Zoning is part of the city plan and should be applied to land at least as early as the street layout is adopted.

Zoning when applied originally to existing cities should be adapted largely to existing facts and normal tendencies.

In the same city, localities having substantially a like character and situation should be zoned in the same manner. This principle should prevent preliminary, emergency, piecemeal or partial zoning.

Zoning should be sufficiently permanent to protect those who comply with the law, but at the same time should be susceptible of change by the municipal legislature under strict checks, so that it can be altered to harmonize with the city's growth.

Provision should be made that property owners may initiate changes or restrict the freedom of the municipal legislature to make specific changes, but the actual application of the zoning regulations to the land, and any changes therein should rest with the municipal legislature and not with the property owners.

Zoning regulations may properly be supplemented by restrictions in deeds based upon purely aesthetic reasons or for the purpose of creating a uniform residential development.

Outside of Zoning's Scope

Regulations applicable to all buildings of a class, regardless of location, such as relate to plumbing, strength of material, safety devices, or protection of employees against fire, should not be placed in a zoning law. They are properly part of a housing law, factory law or building law. Only those requirements which differ in different districts enter into a zoning law.

Zoning by the exercise of the police power of the state must relate to the health, safety, morals and general public convenience of the community. It follows, therefore, that police power zoning must be confined to police power reasons such as fire risk, lack of light and air, congested living quarters and disease-promoting conditions. The preventive regulations based on these reasons, which necessarily must be applied differently and in different measure in different districts, naturally group themselves into zoning according to use, according to height of buildings, and according to bulk, arrangement or area of lot covered by buildings. Zoning could properly go further and embrace building material requirements, commonly called fire limits, fireproof construction, uniform setbacks and doubtless other classes of regulations.

Use districts are residence, business, light industry and heavy industry. Use districts should be few. The more minute adaptation to local needs should be provided for in the area and height zoning, and by permitting special uses under conditions stated in the ordinance or under the administration of a board of building exceptions. Districts described as one-family, two-family, attached house or apartment house, have no intimate relation to the police power and are apt to invite criticism by the courts.

Pressure on Non-Conforming Structures

Where zoning regulations apply only to new buildings (as is the safer practice), non-conforming uses should be placed under a constantly pressing incentive to become conforming through time and changes.

(a) The structural alterations made in a non-conforming building should in no case exceed one-half its value, nor should the building be enlarged, unless its use is changed to a conforming use.

(b) In a residence district, no building or premises devoted to a use permitted in a business district should be changed into a use excluded from a business district.

(c) In a residence or business district, no building or premises devoted to a use permitted in a light industry district should be changed into a use excluded from a light industry district.

(d) In a residence, business or light industry district, no building devoted to a use excluded from a light industry district should be structurally altered if its use shall have been changed since the time of the passage of the ordinance to another use also excluded from a light industry district.

(e) In a residence, business or light industry district, no building devoted to a use excluded from a light industry district should have its use changed to another use which is also excluded from a light industry district if the building has been structurally altered since the time of the passage of the ordinance.

In business and industry districts, towers without limit as to height should be allowed to occupy not over one-quarter of the lot area and they should be allowed on the street line all the way up. They should, however, stand away from side lines according to a suitable rule.

Height limitations should have a relation to street widths. A city, which has no buildings over 150 ft. in height, should allow none over that height.

Included in area limitations, there should be a limitation of families per acre extending from 140 families in the most thickly populated districts to 18 in parts of the suburbs. This regulation should also refer to the arrangement of the buildings and their adaptation for housekeeping units.

An administrative board should have power (a) to rectify on appeals the mistakes of building superintendents in passing on applications for permits; (b) to decide borderline and exceptional cases where specified in the ordinance; (c) to vary the literal requirement of the law where unnecessary hardship is caused and the intention of the law may be equally accomplished by an alternative method to be prescribed.

Not only should the powers of such a board be specified in the ordinance, but the state legislature should authorize the local legislature to create such a board and to delegate powers to it in the ordinance. It is prudent to have the ordinance prescribe a rule of conduct for such a board, as for instance that where unnecessary hardship is caused by the strict adherence to the ordinance, the board may vary the requirement in order to carry out the general purpose of the law in an equally safe or sanitary manner.

CONCRETING IN COLD WEATHER OFFERS STRONG ADVANTAGES TO OWNERS

By A. E. Wells
President, Wells Bros. Construction Co. of Canada, Ltd.

ON the verge of winter; construction blocked in hundreds of cities; a shortage of many materials of construction and of labor; and yet withal, an acute shortage of homes, offices, stores and—in many cities—of office buildings, factories and warehouses,—what is the answer?

The answer lies in winter construction, in proceeding with work during December, January and February, which have been normally "closed" months. Winter work is not new. It has been practised for years, its safety adequately demonstrated, its economy proved. It should be more generally practised.

Any owner who, through prosecuting work during cold weather, can get occupancy of factory or warehouse, or can lease apartments, offices or store space on May 1st, stands to gain far more than the added costs of winter work.

Not only the owner, but builder, engineer and architect, gain. There is financial loss to the contractor who breaks up his trained organization, only to build it again in the spring. New men must take time to accustom themselves to working together and owners pay the bill in increased costs. Architects' and engineers' offices are frequently idle through much of the winter. Building superintendents have nothing to do and owners pay for unproductive overhead.

Perhaps the best way, then, to reduce the cost of building is to keep architects', engineers' and contractors' forces busy twelve months of the year.

Why Does Construction Stop?

Primarily the reason why building has been inactive in winter is that concrete does not harden so rapidly when its temperature hovers near freezing. But we heat our homes, offices and stores, and coal is a comparatively small operating cost. We are to-day able to enclose a structure, warm it with simple coke stoves, heat aggregates prior to mixing with Portland cement, and keep the concrete or mortar warm until hardening has occurred.

Without these precautions, cold weather work is impossible but the precautions are simple and reasonably inexpensive. Why not do the logical thing and consider the winter as an open season for all but the most exposed class of construction?

Our organization has continued to lay brick and place concrete under zero temperatures in Canada. A part of our normal equipment is sufficient tarpaulins to enclose practically any structure and sufficient salamanders or coke stoves to keep such enclosures warm. Boilers of any type, frequently those used to furnish steam for hoisting, supply live steam for heating aggregates and water, and for thawing snow and ice from forms and reinforcing steel.

While a heavy snow may temporarily delay the delivery of materials, yet deep snow is seldom encountered. It is temperature alone that commonly hampers work, and temperature need not be feared.

Plant Layout for Winter

In laying out a plant for handling concrete in winter, or where the work is likely to run on into winter before completion, there must be provision for the proper heating of materials and water. In case of sand and gravel in open storage piles, it is only necessary to lay a grid of steam pipes under the material piles and place a tarpaulin over the pile. From one main through the centre, branches should extend in both directions every 6 ft. These branches should be drilled with ⅛-in. holes spaced about 18 ins. apart. Several hundred yards of material stored in one pile can be heated in this way with the steam from an ordinary hoisting boiler. Several days prior to concreting, steam should be turned into the pile during working hours, which will be sufficient, except at times of extreme cold, to maintain the necessary temperature.

When material is stored in bins, a series of pipes should be laid on the floor of the bins, feeding from a main pipe at the top of the sloping floor. Steam radiates through the entire contents of the bin and if a canvas cover is pulled over the top when work is stopped at night, the material will retain its heat except in very cold weather, when a small amount of steam may be needed at night.

It is necessary also to heat mixing water, and a steam line running directly into the water tank is the customary way; a 1-in. line being sufficient to heat water for a 1-yd. mixer.

But concrete poured into forms exposed to cold would lose its heat before hardening had progressed sufficiently. Forms must, therefore, be protected and the most satisfactory means is a complete canvas enclosure, with salamanders or coke stoves to maintain a temperature of 45 degs., or over, within. Several hours before concrete is poured, salamanders are started in the story below the forms, unless that story is already heated. Immediately after pouring, a sufficient number of salamanders are placed above the new concrete to ensure its safe and thorough hardening. These will furnish heat for the floor above.

This method of enclosure and heating necessitates that the form work for the floor above that being poured shall be in place, in order to serve as a roof under which concrete may be kept warm; although in the case of steel frame structure, it may be possible to support canvas upon the steel because of the floor above.

Posts Set Upon Blocks

Forms for the story above are supported as usual, upon posts, but since the floor slab of the story supporting these posts is not yet poured, it is customary to set the posts upon concrete blocks of the proper depth, so that upon pouring, the block becomes a part of the finished floor. This requires setting blocks to grade and finishing their upper surface.

It is, of course, necessary that the workmen be watched somewhat more carefully on winter work. Snow or ice in the forms is detrimental to good work. Careful inspection is necessary at every stage of the work, but slipshod methods are probably no more likely to affect quality in winter than in summer.

Where the enclosure in canvas is comparatively complete, workers operate at practically normal efficiency, but there are some delays likely to occur through slow delivery of materials during periods of snow. Yet the added costs are more than compensated for by the certainty of quicker occupancy and reduction of interest on money tied up in the incompleted building. It would seem folly to cease work on a structure where there is need of early use.

FEDERAL CEMENT CO., OWEN SOUND

PUBLIC offering will soon be made of $1,000,000 six per cent. first mortgage bonds of the Federal Cement Co., which will operate at Owen Sound, Ont., it is said, but which is incorporated under the laws of the State of Delaware. This issue, it is understood, will be offered to the public at par and interest, with a bonus of 50% of common stock, by a Chicago financial concern.

The officers of the Federal Cement Co. are: J. G. Lind, vice-president of the St. Mary's Cement Co., president; J. E. Murphy, vice-president of the Vancouver Portland Cement Co., vice-president; J. E. Campbell, secretary-treasurer of the Hepworth Mfg. Co., Hepworth, treasurer; A. D. Creasor, of Owen Sound, secretary; with whom L. N. Rosenbaum, president of the Knickerbocker-Wyoming Oil Co., New York, will constitute the board of directors.

The Federal Cement Co. has contracted to acquire the plants formerly operated by the Union Cement Co. and the Imperial Cement Co. at Owen Sound, it is stated, and plans to remodel them to a capacity of 2,000 barrels daily.

$500,000 RESERVOIR FOR WINNIPEG

NOW that the $15,000,000 water scheme for Greater Winnipeg has been brought to a successful conclusion, that city must at once plan for a reserve supply in case of breakdown in any portion of the 100-mile aqueduct between Winnipeg and Shoal Lake, according to an official report which W. G. Chace, chief engineer, has submitted to the Greater Winnipeg Water Board.

This reserve has been figured on before and from time to time discussion upon it has been allowed to drop. Now, however, Mr. Chace says that the time has come for the board to authorize preparation of the plans, with the idea of completing the whole undertaking next summer. Along with the under-drainage, which experts have agreed is necessary, there will be considerable work to be carried out near Deacon as soon as the frost is out of the ground next year.

This reserve plan is a part of the original scheme as recommended in 1913 by the consulting engineers, Rudolph Hering, F. P. Stearns and J. H. Fuertes.

Deacon, about ten miles from Winnipeg, is where the reservoir will be built. It will have a capacity of 250,000,000 gallons, or, on present needs, a reserve supply sufficient to last 20 days.

The cost of the reservoir is estimated at approximately $500,000.

"Winnipeg and district have now the finest water supply anywhere on the North American continent," says Mr. Chace. "But Winnipeg will need a large reserve to be at all safe. If anything should happen to the aqueduct, we would be up against it within two days."

Asked if the city could not go back to the well system in case of emergency, Mr. Chace replied that the reservoir at Deacon has to be constructed sooner or later and the district might just as well do it next year as at any other time. Its maintenance cost would be negligible after construction, he says. Moreover, the wells formerly used could not be placed in shape again without a heavy expenditure, leaving out of consideration the disadvantage of again having to use hard water.

"This will be one of the best opportunities to provide work next summer that the city and district could wish for," says Mr. Chace.

QUEBEC MUNICIPALITIES' ENGINEERING BUREAU

ENGINEERS in private practice are viewing with alarm the growing tendency of governments and public commissions to offer "free" or "at cost" engineering services. The latest addition to the official or semi-official bureaus of engineering information—or, as sometimes happens, misinformation—is in connection with the new Union of Quebec Municipalities, which is to be launched at a meeting in Montreal toward the end of next month or early in December.

At a meeting held last month, thirty Quebec mayors or their representatives attended and appointed a committee to draw up a constitution and operating program. The plan of the association has now been prepared and is to be submitted at next month's meeting, to which twelve hundred Quebec municipal officials will be invited. In commenting upon the new Union, the Montreal Gazette says:—

"One feature of the Union, the constitution of which is drafted after those of the sister provinces, is the creation of a special bureau of consultation for all legal, engineering and accounting matters pertaining to municipalities, a feature which is an improvement on all the existing provincial unions."

The advantages of an engineering bureau of the sort proposed for the Union of Quebec Municipalities, are dubious. Assuming that the appointments to the staff of the bureau are kept out of politics, and that the men selected are very capable engineers of high integrity and great capacity for work, the experiment is still doubtful. Any employe of such a bureau tends to get into certain grooves of practice and to develop "hobbies." All work is standardized along certain lines of established practice and there is likely to be extreme reluctance to adopt new ideas. The municipalities are deprived of the competition of brains and skill that results from the employment of individual engineers or those in private practice. Unless the head of the bureau is also practically the head of his profession, the municipalities are debarred from obtaining the best advice that could be obtained from independent consultations. The head of the bureau may be somewhat in the same position as the "company doctor" in a mining community. Most of the miners prefer to hire their own doctor.

POWER IN BRITISH COLUMBIA

IN British Columbia there is said to be a surplus of developed hydro-electric power. The Vancouver Island Power Co., the Vancouver Power Co., the Western Canada Power Co., and the West Kootenay Power and Light Co., all have considerable power now available, the utilization of which is highly desirable from the standpoint of the capital invested in these companies. A recent suggestion by the "Mining and Engineering Record," of British Columbia, that Commissioner Retallack, who now has charge of the Public Utilities Department of the British Columbia government, should assist these companies in disposing of this power, is a reasonable suggestion and entirely in the interest of industry and employment in the Pacific province.

REPORT ON ST. LAWRENCE RIVER

SIR ADAM BECK, chairman of the Hydro-Electric Power Commission of Ontario, states that the report on the location of the dams for the St. Lawrence river power development, at present in course of preparation, will likely be completed within two or three months. He made this statement when interviewed in reference to the possibility of Toronto and all the large ports along the Great Lakes becoming "ocean ports" in consequence of the St. Lawrence power development, as pictured by Franklin K. Lane, U.S. Secretary of the Interior.

The building of the proposed dams at Morrisburg and the Long Sault raises the water level to accommodate boats of from 25 to 30 ft. draft. Sir Adam pointed out that Ontario would have 1,684 miles bordering on the Great Lakes and rivers, which would, as Mr. Lane says, take care of ocean-going traffic.

"The dam at Morrisburg," he continued, "will regulate the levels of Lake Ontario and create a storage system and largely eliminate floods on the St. Lawrence. It will also create a storage sufficient to make available 20,000 sec. ft. during the periods of the year when the water is low, and will raise the level of the harbor of Montreal from two to three feet.

"We have had engineers working on the St. Lawrence for the past three years, and hope to have the final report on the work in the course of three months, fixing the location of the two dams. That will be most desirable from the standpoint of navigation, and will create 2,000,000 h.p. of electricity, 1,000,000 for the United States and 1,000,000 for Ontario."

LARGE IMPORTS AND EXPORTS

WITH but one-fifteenth the population of the United States, Canada does one-fifth the amount of trade. This statement is based upon official figures just published showing the total of U. S. trade for the year ending August 31st. The comparison is made on the assumption that there are about 8 million people in Canada and 120 million in the United States. The report shows that the U. S. exports for the year totalled $7,415,000,000. Canada's $1,233,000,000, a proportion of one-sixth. Their imports were $3,233,000,000, ours $870,000,000, a proportion of one-fourth. Their total trade was $10,648,000,000, ours $2,103,000,000, a proportion of one-fifth.

PERSONALS

NORMAN McLEOD RAMSAY WILSON, inspector and water works engineer of the Canadian Fire Underwriters' Association, Toronto, has resigned in order to become chief engineer of the Brantford, Ont., water works. Mr. Wilson was born December 3rd, 1869, in Bombay, India. He was educated in England at the Paradise House School and the City and Guilds Technical College, London, where he studied mechanical engineering. Upon leaving college in 1885, he was articled to Richard Johnson, chief engineer of the Great Northern Railway, with whom he spent five years in general railway engineering. Upon leaving the Great Northern, Mr. Wilson spent two years in construction work with Lucas & Aird, contractors, who were then constructing the West Highland Railway, Scotland.

For the following six years he was assistant engineer of the Northeastern Railway, engaged in maintenance and construction of railway and docks. In 1898, Mr. Wilson was appointed assistant county surveyor for the North Riding of Yorkshire, where he spent three years on the design and construction of roads, bridges and public buildings, principally roads. In 1901 he was appointed resident engineer in charge of construction of the Dearne Valley Railway, a colliery line in South Yorkshire, now part of the Lancashire & Yorkshire Railway. In this position Mr. Wilson had further experience in both design and construction, and represented the railway throughout until the contractors turned the road over to the owners, after which he came to Canada in 1907, and secured a position with the bridge department of the Canadian Pacific Railway as resident engineer on the construction of the superstructure of steel bridges, chiefly in New Brunswick. In 1909, Mr. Wilson's services were secured by the Canadian Fire Underwriters' Association, by whom he has been employed continuously for the past ten years. His work with that association has consisted of inspection of water works plants throughout Ontario and the making of recommendations for the improvement of plants from a fire protection standpoint. Mr. Wilson reported upon and kept in touch with the water works and fire protection systems of 212 municipalities in Ontario and also a number in British Columbia. He compiled detailed records of the equipment possessed by every municipality, and also prepared plans of every municipality, showing the location of mains, hydrants, pumping stations, reservoirs, etc. At Brantford Mr. Wilson will be in charge of the proposed extensions to, and reconstruction of, the water works system, and in this work he will have the co-operation of R. S. & W. S. Lea, consulting engineers, Montreal, who have been engaged by the city council to advise regarding methods of increasing the present supply. Mr. Wilson has been a member of the Institution of Civil Engineers of Great Britain for more than 25 years.

SIR ALEXANDER BERTRAM has been appointed treasurer of the Engineering Institute of Canada, to succeed the late Ernest Marceau.

L. R. BROWN, formerly engineer and superintendent of the Toronto Chemical Co., Sault Ste. Marie, Ont., has accepted the position of road engineer with the Dominion Tar & Chemical Co.

DR. F. D. ADAMS, Dean of the Faculty of Applied Science, McGill University, is acting as head of that university until the new principal, Sir Eric Geddes, is free to resume the duties of his office.

ROY A. SPENCER, who served overseas as major of the 3rd Divisional Canadian Engineers, and who returned to Canada two months ago, has been appointed professor of engineering at Dalhousie University, Halifax, N.S.

R. S. L. WILSON is now the official head of the Faculty of Engineering at the University of Alberta, succeeding the late Prof. Muir Edwards. Mr. Wilson's appointment was recently confirmed by the president of the university. Prof. Wilson was formerly a designing engineer on the Welland Canal staff, having previously been a general contractor in Saskatchewan. Recently he has been associated with McGill University and has also acted as consulting engineer for a contracting firm in Montreal.

OBITUARIES

JAMES LOW, a prominent contractor of Ottawa, Ont., fell into the Rideau Canal two weeks ago and was drowned.

BARRY SMITH, resident engineer for the Dominion Construction Co., Toronto, on concrete construction in the Parry Sound District for the C. N. R., was fatally burned in the conductor's van of a construction train when the train was wrecked.

DUNCAN McD. CAMPBELL, of Halifax, engineer on the staff of the Nova Scotia Highway Board, died last week at his home. Mr. Campbell had been in ill-health for nearly a year. He was a native of Truro, N.S. Previous to his appointment two years ago to the staff of the highway board, he was assistant city engineer of Halifax.

R. A. ROSS TO BE E. I. C. PRESIDENT

FOR the year 1920, the president of the Engineering Institute of Canada will be R. A. Ross, city commissioner of Montreal, and chairman of the Lignite Utilization Board of Canada. Prior to his acceptance last year of the city commissionership, Mr. Ross was a prominent consulting civil and electrical engineer.

The report of the nominating committee has been received by the council of the institute. As usual, the president is chosen by acclamation. For all other offices, twice as many men are nominated as are to be elected. The nominations for vice-presidents are:—W. G. Chace, Winnipeg; A. S. Dawson, Calgary; C. H. Mitchell, Toronto; John Murphy, Ottawa.

Following are the nominations for councillors:—District No. 1—F. B. Brown (Montreal), J. Duchastel (Montreal), V. I. Smart (Montreal), and Julian C. Smith (Montreal); District No. 2—F. T. Cole (Quebec), and A. R. Decary (Quebec); District No. 3—F. A. Bowman (Halifax), and W. P. Morrison (Halifax); District No. 4—J. B. Challies (Ottawa), and Alex. Macphail (Ottawa); District No. 5—R. K. Palmer (Hamilton), and E. R. Gray (Hamilton); District No. 6 for one-year term—W. J. Dick (Winnipeg), and B. S. McKenzie (Winnipeg); District No. 6 for a two-year term—Guy C. Dunn (Winnipeg), and J. M. Leamy (Winnipeg; District No. 7—J. R. C. Macredie (Moose Jaw), and C. P. Richards (Regina); District No. 8—G. W. Craig (Calgary), and F. H. Peters (Calgary); District No. 9—H. M. Burwell (Vancouver), and C. Brakenridge (Vancouver).

G. D. Mackie, city engineer and commissioner of Moose Jaw, Sask., has been upheld by the city council in his refusal to permit one of his assistants to make a written report directly to the mayor, although the members of the city council intimate that they think it may be quite in order for the mayor to seek verbal information from any members of Mr. Mackie's department.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Abbotsford, B.C.—The Abbotsford and District Good Roads Association unanimously approved of a resolution to hard-surface the Yale Rd. from New Westminster to Chilliwack.

Ancaster, Ont.—Tenders will be received by W. A. McLean, Deputy Minister of Provincial Highways, Parliament Buildings, Toronto, until 12 o'clock noon on Wednesday, November 5th, 1919, for the clearing, grubbing, earthwork, rockwork, construction of concrete structures and delivering crushed stone on the provincial highway in the vicinity of Ancaster. Plans and specifications may be seen on and after Monday, October 27th, at the office of the Resident Engineer, Paris, Ont.; at the office of the City Engineer, Hamilton, Ont., and at the office of W. A. McLean.

Banff, Alta.—A rate of 52½ cents per hour for ten-hour day has been set by the local authorities in an endeavor to obtain sufficient labor to complete construction of the government road at Temple Siding, between Lake Louise and Banff.

Bridgeburg, Ont.—The Joint International Committee are planning renewal of efforts to have a peace memorial bridge erected. Should this bridge not be constructed, it is expected that an additional commercial bridge will be erected either here or at Fort Erie.

Campbellford, Ont.—Work on the road from Campbellford to Meyersburg, which is a part of the Northumberland county provincial road system, is expected to begin early next spring.

Carsland, Alta.—The provincial Public Works Department will start work at once on the construction of a steel bridge across the Bow River at Carsland, 40 miles e. of Calgary. Estimated cost, $80,000. Hon. A. J. McLean, Minister.

Chatham, Ont.—City council will issue debentures for $75,000, providing for construction of permanent roads throughout the city.

Cloverdale, B.C.—Applications have been received by the Surrey council for improvements on the following roads: Sunnyside, Davis, Newton and White Rock. It is not likely that any new work will be undertaken before next spring.

Goderich, Ont.—Town council contemplates widening South St. on the east side, from Britannia Rd. and Blake St. L. L. Knox, town clerk.

Granby, Que.—The Granby township council will complete, next spring, the construction of the remaining 4 miles of gravelling on the road from Adamsville to Granby township line.

Halifax, N.S.—City engineer is preparing estimates of cost of construction of concrete sidewalks for w.s. of Robie St., from St. Alban to Almon St.; e.s. of Henry St., Coburg Rd. to Morris; and n.s. of Quinpool Rd., from Harvard to Oxford St. F. W. W. Doane, city engineer.

Hastings, Ont.—The Department of Highways has authorized the construction of a first-class metal road from Havelock to Trent River, a distance of between two and three miles. It will be constructed of trap-rock from the Ontario Rock Co.'s quarry at Preneveau, Ont.

London, Ont.—City council intends to construct a cement walk on South McKenzie Ave., from Ridout to a point opposite Marley Place. City clerk, S. Baker.

London, Ont.—Committee has recommended that an estimate of cost of new bridge over the Thames river at Ridout St. be prepared by the city engineer's department. In the meantime, repairs will be made to the old bridge. Estimated cost of repairs, $1,500. H. A. Brazier, city engineer.

London, Ont.—Ratepayers of the eastern district are requesting council to proceed with repairs of pavement on East Dundas St., from McCormick's factory to the city limits.

Montreal, Que.—It is reported that the provincial government intends, next year, to issue debentures providing $10,000,000 for construction of five new provincial improved highways as follows: Montreal—Laurentian Rd., 140 miles; Longueuil—Levis, 180 miles; Levis—Rimouski, 185 miles; Montreal—Sherbrooke, 100 miles; Ste. Thérèse—Hull, 125 miles.

North Vancouver, B.C.—The Good Roads League of British Columbia, at its third annual convention, held here recently, passed a resolution to ask the provincial government to carry out extensive road-building and road improvements. Mayor R. H. Gale, of Vancouver, is president of the league.

Ottawa, Ont.—By-law has been passed ratifying the agreement between the city of Ottawa and the county of Carleton for the taking over of toll roads within the radius of 12 miles from the city.

Ottawa, Ont.—Parts of the Richmond road, extending from Ball's corners to Richmond and from Dwyer Hill to the town line between Goulburn and Beckwith, will be declared a county highway by the passing of the necessary by-law.

Ottawa, Ont.—The new Chaudiere bridge has now been completed with the exception of the roadway. It is expected that the structure will be opened for traffic about December 1st, 1919.

Perth, Ont.—The provincial Highway Department has approved of the construction of a road from Perth to Renfrew, via Lanark and Calabogie.

Peterborough, Ont.—Council has closed Bethune St., between Brock and Murray St., while the C.P.R. is constructing a new bridge over the creek on the Lakefield division.

Portage la Prairie, Man.—Council is considering estimates from the engineer, providing for construction of road

to Delta. Built-up grade, without gravelling, cost, $5,500; with gravelling, $25,000 to $30,000.

Quebec, Que.—City council has adopted report of the civic finance committee recommending expenditure of $50,000 for pavements.

Regina, Sask.—Commissioner Thornton will proceed to improve the boulevard along the centre of Victoria Ave., east of Broad St. The boulevard will be filled, graded and seeded. Alderman Burton.

Rockwood, Man.—Tenders will be received by V. W. McFarlane, secretary-treasurer, until noon on Friday, October 24th, 1919, for the gravelling of approximately 37 miles of road. Plans may be secured from A. McGillivray, Highway Commissioner, Winnipeg, or from D. W. Mawhinney, Municipal Engineer, Stonewall, Man.

Sherbrooke, Que.—Two surveys have been completed for location of the new provincial highway between Beauce and Sherbrooke. One route runs from Beauce Jct. via Thetford, Black Lake and Weedon to Sherbrooke, while the other route runs from Beauceville via St. Evariste to Sherbrooke. Hon. J. A. Tessier, minister of roads has inspected both locations and will soon make definite decision.

St. Thomas, Ont.—The provincial highway, from London to Windsor, will follow the southerly route through St. Thomas, according to Hon. F. G. Macdiarmid, Minister of Public Works and Highways.

Toronto, Ont.—Tenders will be received until noon, October 28th, by the board of control for construction of the following works: Asphalt Pavements—Bristol Ave., from Geary Ave. to 1,000 ft. w.; Herman Ave., from Ritchie Ave. to w. end; Hiawatha Rd., from Applegrove Ave. to Gerrard St.; Sackville St., from Winchester St., to n. end (except intersection of Amelia St.). Granite Block Pavement—Eastern Ave., from St. Lawrence St. to Broadview Ave. (except 227 ft. across Don bridge, railway tracks and sidings). Concrete Curbing—Bristol Ave., e.s., from 150 ft. 6 in. n. of Geary Ave. to 181 ft. farther north. T. L. Church, chairman.

Whitby, Ont—Under the direction of the County Road Superintendent, the county will spend over $3,000 on the Brock St. section of the road. A short cement bridge will be erected.

Windsor, Ont.—City council is considering a proposal to widen London St., between Ouellette and Bruce Ave.; also to pave London St., from Ouellette Ave. westerly.

Winnipeg, Man.—The Good Roads Board authorized construction of 277 miles additional market roads throughout the province. Estimated cost, $678,000.

Yarmouth Tp., Ont.—A petition was presented to the township council, asking that a 4-ft. granolithic walk be constructed on the west side of Park Ave., from Mary St. to Wellington St. Council will obtain a report. Clerk, W. C. Caughell, St. Thomas, Ont.

York Tp., Ont.—A deputation from the Davies estate, Todmorden, requested the township council to lay water mains on the property. Frank Barber, township engineer, will report.

York Township, Ont.—Contracts have been awarded by township council for construction of sidewalks as follows: Barr Ave., to Angotti and Smythe, $1,175. Rejected tender, Sheridan, $1,757; Brownhill Ave. to Sheridan, $2,924. Rejected tenders from Angotti and Smythe, $4,350; A. Johnson, $4,140. Eversfield Ave. to Grant, $3,950. Rejected tenders, A. Johnson, $5,125; National, $4,988; Sheridan, $7,074.50. Glenholme Ave., s. of Medway Ave., to Township Engineer, $958. Rejected tenders from A. Johnson, $1,800; National, $1,508; Sheridan, $1,453.80. Keene St., to A. Johnson, $1,350. Rejected tenders from National, $1,580; Sheridan, $1,768. Lauder Ave., to Township Engineer, $750.75. Rejected tenders from A. Johnson, $950; National, $888; Sheridan, $1,256.70. Pape Ave., to J. E. Clarke, $4,500. Rejected tenders from Grant, $4,775; A. Johnson, $6,000; National, $6,788; Sheridan, $7,316; Walton and Rowell, $6,300. Weston Rd., to National, $3,988. Rejected tender from Angotti and Smythe, $4,232; A. Johnson, $4,300; Sheridan, $6,233. Frank Barber, engineer.

WATER, SEWAGE AND REFUSE

Amherstburg, Ont.—Tenders will be received until Octoger 25th by Anderdon township council for cleaning out and enlarging the Sinasac drain. A. C. Mailloux, clerk, Amherstburg.

Brantford, Ont.—Lee and Lee have presented to the Water Commission an estimate of the cost of constructing a filtration system here, estimated cost being from $500,000 to $600,000.

Calgary, Alta.—The Utilities Commission Board has approved plans for a new sewage disposal plant for the city of Calgary. By-laws will probably be submitted to the ratepayers at an early date.

Edmonton, Alta.—The provincial Public Utilities Commission have granted permission for towns to issue debentures as follows: Grande Prairie, town hall and waterworks extension, $10,500; Drumheller, waterworks extension, $21,000.

Fort Erie, Ont.—The village council has let the contract for the new suction wheel to be sunk at the waterworks pump-house to Bradley Wheeler at a price of $1,900.

Halifax, N.S.—City council will call for tenders for construction of sewer on Carteret St. F. W. W. Doane, city engineer.

Halifax, N.S.—The following contracts will soon be awarded by the city council: 6-in. water main on Barrington St., from Hurd St., s. 300 ft.; water main in lane from the Infectious Hospital to Robie St.; water main on Connolly St., from Chebucto Rd., n. 300 ft.; water main on MacDonald and Patricia Sts., from Flynn St. to Chebucto Rd.; sewer and water mains on Russell St., from Robie St., e. 400 ft.; sewer on North Park St., from Cogswell St. to Cornwallis St.; sewer on Kline St., from Quinpool to Oak St.

Hamilton, Ont.—Council contemplates construction of a sewer extension along Burlington St. to the new site of the Firestone Tire and Rubber Co. Estimated cost, $34,000. E. R. Gray, city engineer.

Hamilton, Ont.—Contracts will soon be awarded by Board of Control, City Hall, Hamilton, for the construction of the following pipe sewers: Cannon St., from Gage Ave. to Balsam Ave.; Paradise Rd., from Dundas St. to a point 250 ft. south of Adelaide St.; Aberdeen Ave., from a point 120 ft. west of Chedoke Ave. to a point 210 ft. westerly; Macnab St., from Hunter St. to a point 190 ft. northerly; Ottawa St., from Main St. to Maple Ave. E. R. Gray, city engineer.

Hawkesbury, Ont.—F. A. Dallyn, provincial sanitary inspector, has inspected and approved the filtration plant recently completed for the town of Hawkesbury. Contractors, Archambault and Leclair, Montreal. Engineers, Jas. O. Meadows, Montreal.

Kingston, Ont.—Board of Health recommends to council construction of sanitary sewers on Macdonnell St. and on Lansdowne St. westerly to west limit of lot No. 1.

Kingston, Ont.—City council has granted the application of the Civic Utilities Commission for construction of the following works: Water main on Ellerbeck St., between Union and King St.; water main on Concession St., between Victoria and Princess St.; gas main on Brock St., between Nelson and Victoria Sts.

Kirkfield Park, Man.—Tenders will be received until 4 p.m., November 4th, for construction of a sewer, laying of water mains, valves, hydrants, etc., on Queen St., St. James, from Portage Ave. to Silver Ave. Frank Ness, secretary-treasurer.

Kirkfield Park, Man.—The council of the rural municipality of Assiniboia contemplate construction of a 5-in. well

Brant Road, Galt, Ont. Tarvia modified modern pavement built in 1911. Treated with "Tarvia-B" in 1916.

A view of St. Andrews Street, Galt, Ont. Surface-treated with "Tarvia B" in 1916 and 1918.

Tarvia

Preserves Roads
Prevents Dust

Tarvia Streets in Galt, Ont., have made good—

BRANT ROAD, shown above, was constructed in 1911 with "Tarvia-X." In 1916 it was treated with "Tarvia-B." The photograph was taken two years later, and a finer street would be hard to find. Not a hole or a patch or a ravelled spot in the whole stretch !

And this street can be *kept* in first class condition for many years with an appropriate Tarvia treatment at very small cost.

The small photograph in the oval shows St. Andrew's Street, built originally as a water-bound macadam street and treated with "Tarvia-B" in 1916 and again in 1918.

This street shows what can be done by surface-treating old water-bound macadam with Tarvia if it is taken in time. Systematic surface treatments with Tarvia will keep this road in fine condition indefinitely.

Tarvia is ideal for city and town residental streets because a Tarvia street is dustless and mudless and easy to keep clean. Taxpayers like Tarvia streets because of these features, and also because they can be maintained very economically.

Galt is only one of the scores of Canadian cities and towns that are solving their street problems with Tarvia.

If your community is facing any road construction or re-construction problems, or if you require an efficient dust preventive, road preserver or patching material, it will certainly pay you to investigate Tarvia.

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by anyone interested. If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention. Booklets free.

The Barrett Company LIMITED

MONTREAL. TORONTO WINNIPEG
VANCOUVER ST. JOHN, N.B.
HALIFAX, N.S. SYDNEY, N.S.

and equipping same with pump and platform. F. Ness, secretary-treasurer.

Lindsay, Ont.—Town council is considering the construction of a relief storm sewer from Kent St. to Peel St. as part of a comprehensive storm sewer from the head of Sussex St. Estimated cost, $1,500. Town engineer, O. Smith.

London, Ont.—City council intends to construct a 10-inch sewer on both sides of Sackville St., from Hamilton Rd. to Grafton St., at an estimated cost of $5,889.15. City clerk, S. Baker.

London, Ont.—City council contemplates a policy of concrete bridge construction to replace the existing steel structures, which are rapidly wearing out. Estimated cost of concrete bridge over Thames River at Ridout St., if authorized, would cost approximately, $50,000.

Midland, Ont.—Council has passed by-law providing for extension of the waterworks and lighting systems, construction of which is partly completed. Estimated cost, $30,000.

Moncton, N.B.—Contract has been awarded by city council to Lewis Stevens for construction of sewer on North St. Estimated cost, $5,065. J. Edington, city engineer.

Port Hope, Ont.—Contract has been awarded by town council for construction of sewer on Princess St. to A. A. Outram. Contract price, $800.

Saskatoon, Sask.—Application will be made by the city to the Local Government Board for permission to extend sewers and water mains to the property recently acquired by the North Star Oil and Refinery Co. on Avenue P. Estimated cost, $3,500.

St. John, N.B.—Armstrong and Bruce have requested the city council to extend water and sewage mains into the Mt. Pleasant Court subdivision. Estimated cost, $2,000.

Vancouver, B.C.—The report of the Vancouver and Districts Sewerage and Drainage Board shows that the total cost of constructing the extension of the Bridge St. drainage system was $20,000 less than the lowest tender submitted for this work.

York Township, Ont.—The following contracts have recently been awarded by the council for construction of water mains: Murphy, Belvidere, 6 in., $874; Bathurst St., 12 in., $3,776.20; Corbett St., 6 in., $1,456.92; Sunnybrae, 6 in., $1,066.30; Forest Hill, 6 in., $5,513.78. Rejected tenders, McAuslan and Anderson, Belvidere, $1,081; Bathurst, $6,277; Corbett, $2,882.05; Sunnybrae, $2,122.75; Forest Hill, $8,356.30. From Cavotti, Belvidere, $904; Bathurst, $4,781.50; Corbett, $1,516.30; Sunnybrae, $1,139.45; Forest Hill, $7,160.95. From Grant, Corbett, $2,051.19; Forest Hill, $6,749.66. Frank Barber, engineer.

LIGHT, HEAT AND POWER

Glace Bay, N.S.—The Dominion Coal Co. plans installation of steam turbines to utilize all waste and exhaust steam in developing additional electrical energy. This power would be used for the entire electrification of all new and proposed mines under control of the company.

Glencoe, Ont.—Ratepayers passed a Hydro enabling by-law.

Nanton, Alta.—The provincial Public Utilities Commission have granted permission for issue of debentures for construction of improvements to the electric light plant.

Rivers, Man.—Debentures will be issued by the town of Rivers, providing for installation of electric lighting system and equipment. Debenture issue, $9,000. E. J. Forman, secretary-treasurer.

Toronto, Ont.—The Toronto Hydro-electric will shortly apply to council for $700,000 new capital to provide for large extensions to the system. T. Church, mayor.

Wingham, Ont.—By-laws have been passed by the ratepayers, enabling and authorizing the Hydro-Electric Power Commission to construct a distributing plant, $40,000. Power will be obtained from Eugenia Falls, Ont.

RAILWAYS

Edmonton, Alta.—It is proposed to extend the street railway system down Brandon Ave. in West Edmonton.

Edmonton, Alta.—The city council has granted permission to the C.N. Ry. to construct spur track extensions in the city, between 107th and 108th Sts. to Athabasca Ave.

Elmira, Ont.—The Ontario Hydro-Electric Commission has prepared estimates of the cost of an electric railway, from Elmira to Kitchener, Galt and Dundas connecting with the contemplated lines from Toronto and London and to Niagara Falls as well as from Guelph to Preston and Galt. This information is contained in a letter received by the city council from Sir Adam Beck.

Galt, Ont.—The engineers of the Hydro-Electric Power Commission have prepared a report on the proposed Hamilton-Elmira radial. By-laws will probably be submitted, on or before January 1st, 1920, to the ratepayers of Hamilton, Galt, Preston, Hespeler, Guelph, Kitchener, Waterloo and Elmira. Sir Adam Beck, chairman.

Montreal, Que.—Ratepayers of the Park Ave. extension district will request extension of car lines through Beaumont, Bremner and Ball Sts.

Saskatoon, Sask.—Council has decided to extend the street railway system along Twentieth St. to the n. side of Avenue H. Estimated cost, $1,818. The intersection of this street will have a bitulithic pavement. Estimated cost, $3,573. Commissioner Yorath.

Sydney, N.S.—Board of works has recommended to council to grant permission for the installation of a new siding, 320 ft. in length, on Victoria Rd., near the fire station.

Toronto, Ont.—The Ontario Railway Board has approved plans for construction of Bloor St. civic car line extension.

Toronto, Ont.—The Toronto and Eastern radial by-law will be voted on by West Whitby, Whitby town and Bowmanville on November 17th, and Scarboro' township and Oshawa on November 22nd.

Toronto, Ont.—The Ontario Railway Board has approved the plans of the civic car line on West Bloor St., from Quebec Ave. to Runnymede Rd., and the Board of Control has decided to recommend that the necessary $160,000 for the double-tracking be financed without seeking the approval of the ratepayers.

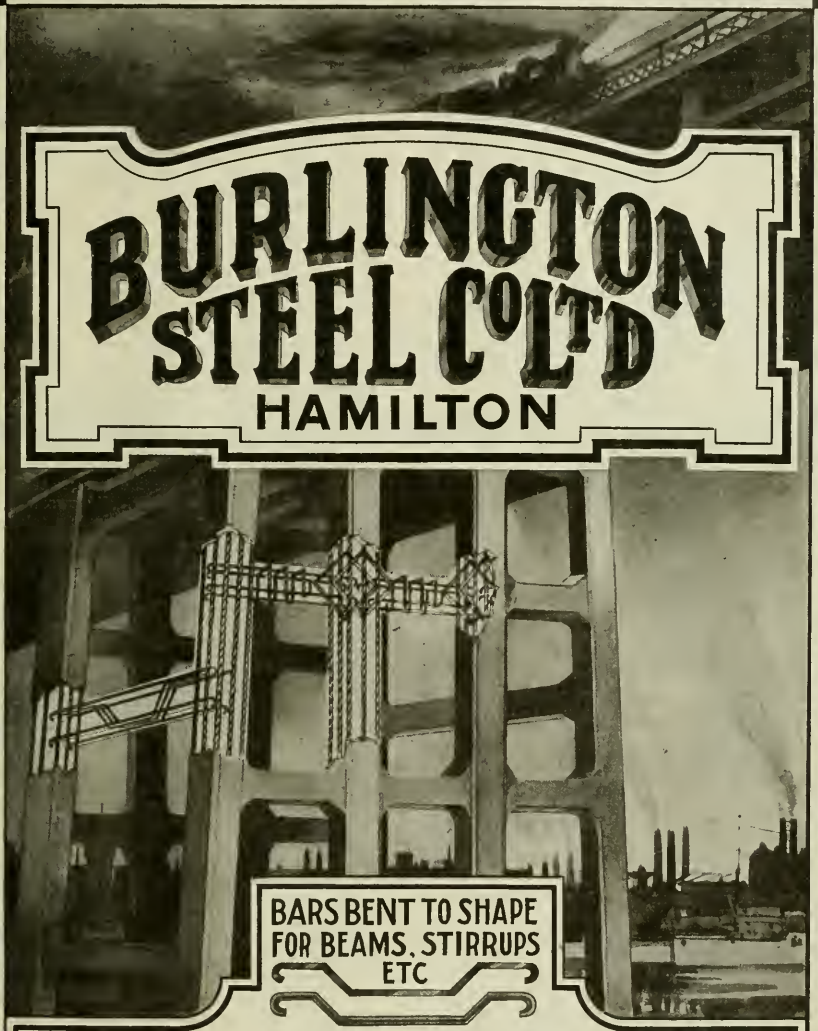
Toronto, Ont.—Application has been made by the Hydro-Electric Power Commission of Ontario to the Ontario government for two orders-in-council, one of which is to permit the Commission to enter into negotiations with the Detroit United Railway for the acquiring of the properties of the Sandwich Windsor and Amherstburg Railway Co. and the Windsor-Tecumseh Co., which also include the electric distribution systems in the municipalities of Windsor and Sandwich. The amount involved is over $2,000,000. The second order-in-council is to enable the Commission to have by-laws submitted to the electors of the several municipalities on the line of the proposed railway from Hamilton to Elmira via Galt, covering the estimates and agreements for the construction and operation of the line.

Windsor, Ont.—The Hydro-Electric Power Commission has applied for an order-in-council for permission to submit a by-law to the ratepayers of the border municipalities authorizing purchase of the Sandwich, Windsor and Amherstburg street railway. Estimated purchase price, $2,000,000. Sir Adam Beck, chairman.

FACTORIES AND LARGE BUILDINGS

Bienfait, Sask.—It is rumored that the Dominion government will establish the new lignite briquetting plant at Bienfait, and that construction will commence in April, 1920.

Belleville, Ont.—The Ontario Oakoal Co. will erect a plant for manufacture of Oakoal. The city garbage disposal question will be solved by delivery to the new company.



BURLINGTON STEEL CO LTD
HAMILTON

FLATS, ANGLES.

Campbellford, Ont.—The town council carried a motion at a recent meeting authorizing the town solicitor to prepare a by-law to raise by debentures $69,000 for the purpose of building a new high school.

Chatham, Ont.—Engineers who have charge of the solution of Chatham's water problem have made a preliminary report of the cost of alternative schemes for the future source of supply. It is estimated that to bring water from the Snve Carte will cost $720,000, from Lake Erie $600,000, and from the River Thames $300,000. Tests show that the lake water is the most satisfactory.

Dartmouth, N.S.—By-laws have been passed which will bring the town under the provisions of the Nova Scotia Housing Act. The following commissioners have been appointed; W. H. Covert, G. Mitchell, R. Elliott for a term of three years each, Capt. Livingston and J. J. O'Toole, one year each.

Didsbury, Alta.—The contract for the new high school has been awarded to Emerson Morrison, of Didsbury. Architect, Charles Hay, Calgary.

Edmonton, Alta.—City council will construct a rest and check room at the East End park. Estimated cost, $4,000.

Edmonton, Alta.—Permission has been granted by the provincial public utilities commission for issue of debentures as follows; Fort Saskatchewan, school, $11,000; Vegreville, school, $10,000.

Fort William, Ont.—The city council has authorized the mayor and clerk to sign agreement turning over the site for the new skating rink to the Fort William Arena Rink Co.

Glace Bay, N.S.—The town council has been authorized to borrow $20,000 for construction of a new school to relieve congestion at the Central school on Park St.

Glencoe, Ont.—The I.O.D.E. are raising funds for construction of a proposed memorial hall.

Halifax, N.S.—Plans are being formed for construction of a new synagogue. Estimated cost, $30,000.

Halifax, N.S.—Plans are being prepared for construction of a new Baptist temple on the corner of North and Brunswick St., and a new parsonage across the road. Estimated cost, $75,000. Rev. H. R. Boyer, pastor.

Hamilton, Ont.—The Norton Co. of Canada, Ltd., will construct factories on Lottridge St. immediately.

Hamilton, Ont.—Contract has been awarded to J. B. Nicholson, Ltd., of this city, for the erection of a $50,000 reinforced concrete elevator for the Yates-Lehigh Coal Co., Buffalo, N.Y.

Hamilton, Ont.—By-law will be submitted to the ratepayers on January 1st, providing for construction of fences, grounds, bleachers and stands for the proposed athletic field at Scott Park.

Hanover, Ont.—A movement is on foot to collect $40,000 for the erection of a Y.M.C.A. building.

Ingersoll, Ont.—By-law has been passed by the ratepayers providing for construction of a new sixteen-room school. Estimated cost, $120,000.

Kingston, Ont.—The urgent need for a new school was brought to the attention of the members of the Board of Education in a report submitted by Inspector J. Russell Stuart.

Lethbridge, Alta.—Contract for alterations to the general offices in the local C.P.R. depot has been awarded to Smith Bros. and Wilson, for the general work. The electric fixtures will be installed by the Roy Electric Co., and the heating by the Hick-Sehl Hardware Co. Work is now going on. Total estimated cost of alteration, $7,000.

London, Ont.—A High and Public School extension programme, to be carried out next summer, which will entail an expenditure of half a million dollars, is projected by the Board of Education. Chief inspector, C. B. Edwards.

London, Ont.—An announcement has been made that the Arts Faculty of the Ursuline Academy of Chatham and L'Assomption College, Sandwich, which were recently affiliated with the Western University here, have purchased 40 acres of land adjoining the new site for the university. Both the college and academy will proceed without delay with the erection of buildings to cost between $100,000 and $150,000 each.

London, Ont.—Contract has been let to John Putherbough, of London, for the erection of a new medical college building. Approximate cost, $305,000. The work will be undertaken at once.

Moncton, N.B.—Project is under way for construction of a large skating rink building.

Montreal, Que.—W. A. Humphrey has commenced construction of a two-story garage, size, 50 by 100 ft., on the site of the old curling rink on Mechanic St.

Montreal, Que.—The Canadian Steel Tire and Wheel Co. is constructing a large plant at Montreal for manufacturing steel tires for railway equipment.

Montreal, Que.—Work has been started on the foundations for a new reinforced concrete building on Phillips Square. The work is being done by the Foundation Co., Ltd., Montreal. Ernest Cormier, New Birks Bldg., is the architect. The building will have 175 ft. frontage on Phillips Place with a depth of 134 ft., and will be eight stories high.

Montreal, Que.—The Canadian Vickers Co. have announced their intention of forming an amateur athletic body amongst the employees of the shipbuilding concern, and plans are already under way for the construction of a large clubhouse. A site is now being sought in Maisonneuve.

Nelson, B.C.—At a recent meeting of the Board of Trade a resolution was unanimously adopted, calling for the Dominion government to provide an ore-testing plant to the interior. F. A. Starkel, E. W. Widdowson and R. W. Hinton were appointed a committee to draft a telegram on the subject, to be dispatched to the federal Minister of Mines.

New Westminster, B.C.—The Housing Committee will shortly call for tenders for the erection of houses.

Northern Ontario.—The Associated Goldfields Mining Co., Ltd., which possesses large areas at Larder Lake, in Northern Ontario, proposes to erect a large mill. General superintendent and manager, C. G. Daimpre.

Oak Bay, B.C.—Ratepayers passed a by-law authorizing the erection of a new school building.

Oshawa, Ont.—J. F. Burke is making extensive alterations to the Central Hotel. Estimated cost, $8,000.

Ottawa, Ont.—The Carnegie Public Library Board has awarded contract for changes in the main hall to Taylor and Lasky. Board also contemplates construction of branch libraries in Ottawa South, estimated cost $25,000, and on King Edward Ave., estimated cost $35,000. W. G. Black, chairman.

Peterborough, Ont.—The McDonald Lumber Co. will erect a new box factory immediately, and other extensions in the near future. The site of the new addition is a section of Crescent St., between Rink and Perry St. and has been purchased from the city council for $25. C. McDonald, Peterborough.

Peterborough, Ont.—The Nashua Gummed and Coated Paper Co. will remodel and equip the old cordage works. Construction will soon commence.

Point Grey, B.C.—Seventeen additional new homes will be constructed by the housing commission.

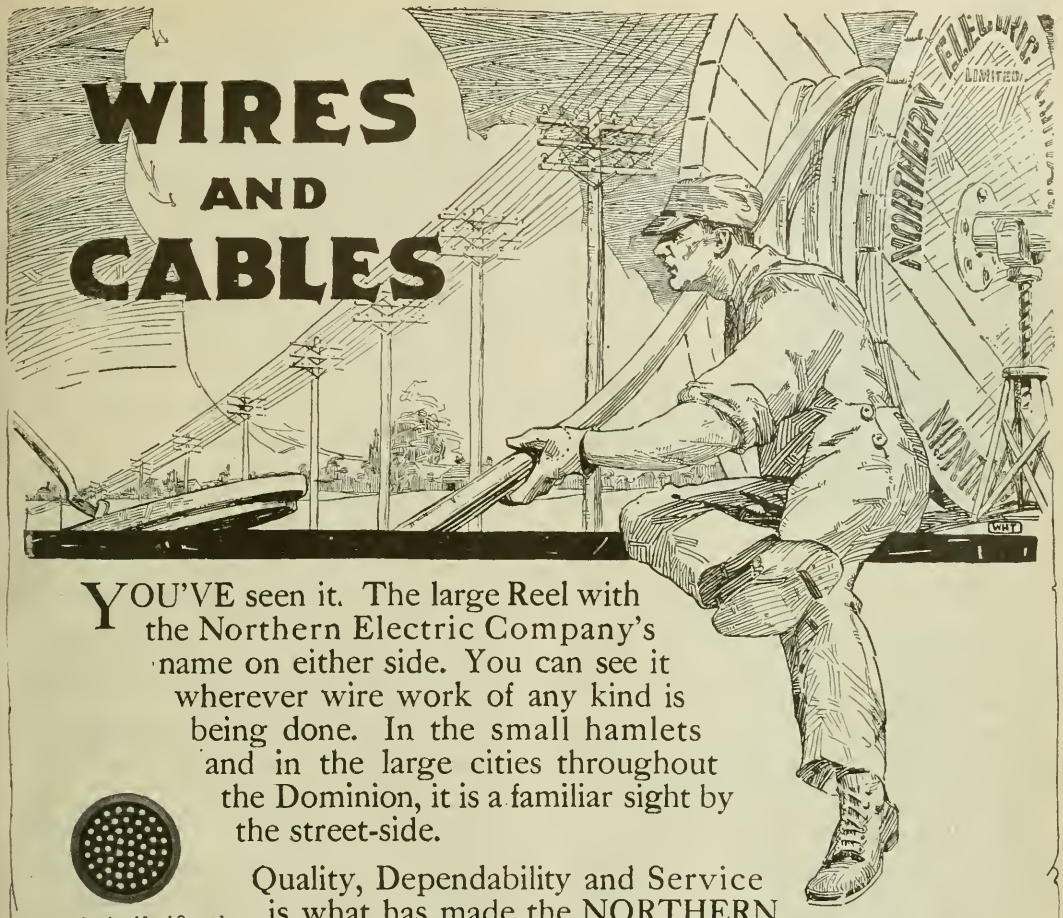
Quebec, Que.—Contract has been awarded to J. Gosselin for construction of the new chapel to be built in St. Lawrence Ward, Levis. Contract price, $7,000.

Regina, Sask.—The Ford Motor Car Co. of Canada, Ltd., contemplates construction of a factory. Estimated cost, $100,000.

Regina, Sask.—Contract has been awarded by the S.O.E. for construction of an addition to hall to F. Chestnut. Contract price, $2,200.

Renfrew, Ont.—The Carnegie Corporation of New York have granted funds for construction of a public library building. Amount available, $16,000.

WIRES AND CABLES



YOU'VE seen it. The large Reel with the Northern Electric Company's name on either side. You can see it wherever wire work of any kind is being done. In the small hamlets and in the large cities throughout the Dominion, it is a familiar sight by the street-side.

Renfrew, Ont.—Ratepayers have passed by-law providing for construction of a new fire hall, which will also contain a central heating plant. Estimated cost, $25,000.

Rockyford, Alta.—Tenders will be received until noon, October 31st, by the board of trustees, Jarvis School district No. 3827, for erection of a frame school building. F. G. B. Swigart, secretary-treasurer, Rockyford, Alta.

Sandwich East, Ont.—The General Motors Corporation have purchased land on Walker Rd. as a site for their model townsite. Estimated cost of buildings, $1,000,000.

Saskatoon, Sask.—City commissioners will request loan of $200,000 from the government for construction of dwellings.

St. Hippolyte, Que.—Tenders will be received until November 8th, by the Protestant school commission, for construction of the Protestant School of Saint Hippolyte. Joseph Gohier, secretary-treasurer.

Stratford, Ont.—By-law will be submitted to the ratepayers on January 1st, 1920, providing for completion of improvements and construction of buildings at Queen's Park. Estimated cost, $25,000. R. T. Orr, chairman, parks board.

Thornbury, Ont.—The Thornbury grist mill, which was owned by that town, and operated by W. Moore and Sons, of Meaford, Ont., was completely destroyed by fire recently. Estimated loss, $20,000. The Thornbury electric lighting plant, which was located in the same building, was also destroyed.

Toronto, Ont.—Members of St. Patrick's parish will erect a parish hall.

Toronto, Ont.—The Downes Dunlop Co. will construct a three-story brick store and apartment at the corner of Danforth and Pape Ave. Estimated cost, $50,000.

Toronto, Ont.—Plans have been prepared for construction of a new reception hospital for incipient cases of insanity. Plans provide for a main building with four angle wings, main building to be two-story and basement. Commissioner Chisholm, property department.

Toronto, Ont.—The Board of Education will call for tenders for the erection of a caretaker's house on the Norway School grounds, the building to be constructed from the material of the house now being torn down to make way for the addition to the school. The price limit fixed is $3,500.

Toronto, Ont.—A building permit has been issued by the city architect's office for the erection of the Northern Aluminum Co's new warehouse and factory on Sterling Rd., which is to cost $358,000.

Toronto, Ont.—According to a statement made recently by Rabbi Jacobs, of Bond St. Synagogue, it is intended in the near future to build a new synagogue in the north-west section of the city which will be the largest of its kind in Canada.

Toronto, Ont.—Geo. W. Gouinlock, architect, submitted plans to the Board of Education for the proposed addition to Parkdale Collegiate Institute. Accordingly, the architects were instructed to submit estimates so that tenders could be asked for.

Trenton, Ont.—The Chemical Products of Canada, Ltd., proposes to erect a plant here.

Vancouver, B.C.—Plans are being prepared for construction of a large modern auditorium theatre to have a seating capacity of 2,200. H. J. Porter, secretary-treasurer.

Vancouver, B.C.—The Sumner Metal Works, of Everett, Wash., has decided to establish a Canadian factory. The plant of Allan & McKelvie has been secured and will be enlarged to the required capacity. A. McKelvie, secretary-treasurer.

Waterloo, Ont.—Excavation has commenced on foundations for construction of a two-story addition to the Mutual Life Assurance Co. building. Architect, H. Horner, Toronto.

Winnipeg, Man.—The Winnipeg housing commission will construct 200 houses next spring.

Winnipeg, Man.—Carter, Halls and Aldinger have commenced construction of new plant in St. Boniface for the Western Wheel and Foundries Co. Estimated annual capacity of plant, 100,000 car wheels.

Winnipeg, Man.—Construction has commenced on the first temporary building, which will contain 25,000 sq. ft. of lecture space, and will accommodate 900 students for lectures and laboratory work. Estimated cost, $85,000.

Winnipeg, Man.—The Winnipeg Housing Commission will construct three houses on Hart St., Elmwood. The houses will be constructed in red brick, and will be of four, five and six rooms. H. C. Thompson, chairman.

Winnipeg, Man.—Archbishop Matheson, of the Anglican church, is planning erection, next year, of a memorial cathedral, to be constructed on the banks of the Red River in commemoration of the centenary of the establishment of the church.

Yarmouth Tp., Ont.—Township council passed a by-law to provide for the erection of two schools. Clerk, W. C. Caughell, St. Thomas, Ont.

Zurich, Ont.—H. Gundel, of London, will establish a glove factory here.

MISCELLANEOUS

Amherstburg, Ont.—The Detroit and Windsor Ferry Co. will soon complete construction of the new concrete docks. The floors in the waiting-room and shelter will be finished in concrete and tile.

Collingwood, Ont.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Thursday, November 6th, 1919, for the breakwater reconstruction, being the renewal of the superstructure of part of the eastern breakwater at Collingwood. Plans may be seen and specification obtained at the Department of Public Works, Ottawa; at the office of the District Engineer, Equity Building, Toronto, Ont., and at the post-office, Collingwood, Ont.

Edmonton, Alta.—Permission has been granted by the provincial public utilities commission for issue of debentures as follows: Mundare, fire protection, $8,000; Vermilion, fire hall and fire protection service, $20,000.

Esquimalt, B.C.—Skinners Cove, Esquimalt, has been selected as the site of the drydock to be built by the federal government.

London, Ont.—City council contemplates purchase of three vacuum sweepers for street cleaning. Contract for flusher recently called by tender will not be awarded until the vacuum sweepers have been tried experimentally. H. A. Brazier, city engineer.

New Westminster, B.C. — City council contemplates dredging the Fraser river at Peplar Island shipyard.

Niagara, Ont.—The lake level committee of the Sanitary District board, Chicago, has recommended the immediate construction of a system of gates in the Niagara and St. Lawrence rivers, at the expense of the Sanitary district. The gates are proposed to assure surface elevations of Lakes Michigan, Huron and Erie, and the lower St. Lawrence River, which will all remain at the present levels in spite of the proposed diversion of 10,000 c.f.s. from Lake Michigan at Chicago.

Ottawa, Ont.—Tenders will be received until noon, November 8th, for manufacture, supply, delivery and erection of kitchen equipment for the new parliament buildings, Ottawa. J. A. Pearson, architect.

Outremont, Que.—Council contemplates construction of an incineration plant which will burn garbage as fuel for raising of steam to operate sewer pumps. Estimated cost of building and plant, $15,000.

Quebec, Que.—It is the intention of the Harbor Board to rush to completion the work that has already been started on the waterfront and to make the improvements that have been decided upon, including the construction of concrete and brick sidewalks to replace the present wooden ones.

At Last!
A Real Highway Handbook

IF this book was merely an accumulation of data, it would never serve as a sound reference for those engaged in highway work.

BUT, this book is a great deal more—it has been prepared by 18 engineers who selected their data with the utmost care—data that would be usable every day of the year—good, sound, and thoroughly practical. All of this material was then carefully edited and arranged for instant reference—making it easy to find just what you want in the

American Highway Engineers' Handbook

ARTHUR H. BLANCHARD, Editor-in-Chief and
Seventeen Associate Editors.

Wide popularity has already been attained by this book. Men in highway work buy it because it gives the most complete reference to all types of highway construction, streets, paving, etc., in fact, everything that they want to know.

You can consult with confidence, any of the pages in this book ; eighteen of the foremost engineers of the country have given their best efforts to it ; it is the authority. In short, if it's in " Blanchard," it's right.

Verdun, Que.—The city engineer has been authorized by the city council to prepare a report for presentation to the federal government with a view to securing aid in the construction of a dike.

Victoria, B.C.—Tenders will soon be called by the Dominion government for construction of the Esquimalt drydock. Borings are being taken and the plans will soon be completed. Dr. S. F. Tolmie, minister of agriculture.

Wiarton, Ont.—The town council has sold the casket factory to C. Hill. Purchase price, $7,000. New machinery will be installed and many improvements made. J. H. Fielding, town clerk.

Winnipeg, Man.—The Laura Mines, Ltd., a new mining company in northern Manitoba, has been incorporated with a provincial charter and a capital stock of $2,000,000. The mine is situated in the Rice Lake district.

Tenders Called For

NOTICE TO CONTRACTORS

Sealed tenders, marked, "Tender for Ancaster Hill Work," will be received by the undersigned until twelve o'clock noon on Wednesday, November 5th, 1919, for the clearing, grubbing, earthwork rockwork, construction of concrete structures and delivering crushed stone on the Provincial Highway in the vicinity of Ancaster.

Plans, specifications and forms of tender may be seen on and after Monday, October 27th, at the office of the Resident Engineer, Paris, Ontario; at the office of the City Engineer, Hamilton, Ontario, and at the office of the undersigned.

A marked cheque for Five Hundred Dollars, payable to the Minister of Public Works and Highways, Ontario, must accompany each tender.

A Guaranty Company's Bond for ten per cent. of the amount of the tender will be required when contract is signed.

The lowest or any tender not necessarily accepted.

W. A. McLEAN,
Deputy Minister of Highways.

Department of Public Highways,
Toronto, October 15th, 1919. 366

A Weekly Paper for Civil Engineers and Contractors

Walkerville Underground Sewage-Pumping Plant

Circular, Two-Story, Reinforced Concrete Structure, Approximately 23 ft. Diameter and 20 ft. High, Built Entirely Below Ground Level Excepting Housing for Stairway—Lower Compartment, Containing Pumps, Encircled by Suction Well and Force Main

By CHARLES W. TARR
Deputy Chief Engineer, Morris Knowles, Ltd., Windsor, Ont.

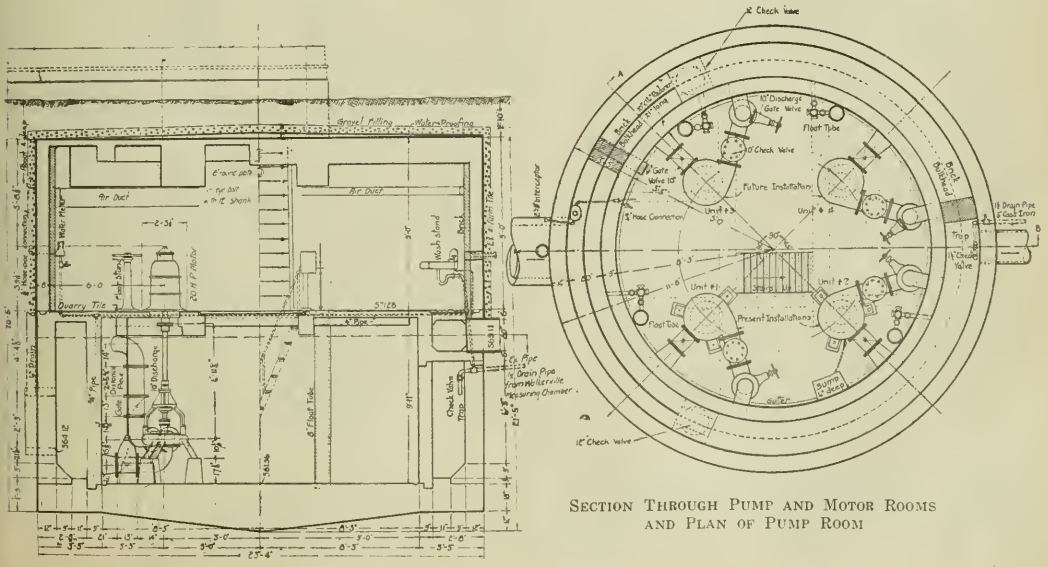
THE sewage pumping station referred to in this article is located in Walkerville, Ont., and is part of a general scheme of the Essex Border Utilities Commission to provide sewerage and sewage disposal for the Essex Border District. This district includes an area about 2 miles wide by 10 miles long, bordering on the Detroit River, and includes Windsor, Walkerville, Ford City, Sandwich, Ojibway and portions of the townships of Sandwich West and Sandwich East.

The commission now has under construction 2½ miles of intercepting sewer to serve the south end of the district, and in June last completed 2½ miles of sewer which will serve the east end, the latter sewer being known as the east interceptor.

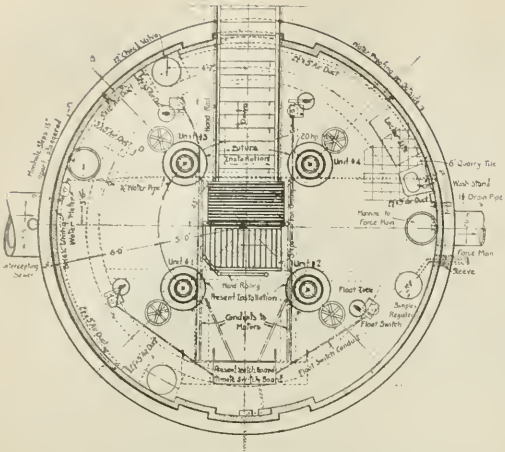
The Walkerville pumping station is necessary to complete and put into operation the east interceptor. Owing to the level topography along the Detroit river, the depth to which it would have been necessary to carry the interceptor to secure a proper gradient, would have been prohibitive, so provision has been made to raise the sewage at an intermediate point, from which it will again flow by gravity to the disposal site. Until such time as the central section of the interceptor is built, the sewage will pass through a temporary outlet into the Detroit river below the water works intakes.

The pumping station is a circular, two-story, reinforced concrete structure, 23 ft. 4 ins. in diameter and 20 ft. 5 ins. high, all built below ground with the exception of the superstructure which houses a stairway leading to the floors below, somewhat on the style of a subway entrance. The upper compartment contains the electric motors, while the lower compartment contains the vertical pumps and is entirely encircled by an annular suction well, above which is the force main. The circular design for the station was chosen, after a careful study of all the factors, because it gave a very efficient and compact arrangement for the pumping units, and allowed a very considerable saving of reinforcing steel and concrete.

The pumping equipment will consist of four units, two of which will be installed at present. The other two will be added when required. Each unit consists of a 20-h.p. vertical motor and a 2,000-gal. vertical centrifugal sewage pump. The units will be automatic in operation, and the motors will



SECTION THROUGH PUMP AND MOTOR ROOMS AND PLAN OF PUMP ROOM



PLAN OF MOTOR ROOM

be started and stopped by a float-operated switch attached to a copper float in an 8-in. wrought-iron float tube, and actuated by the rise and fall of sewage in the suction well. For the present population served by the station, one pump will be sufficient and the other will be used as a spare and later to assist during peak load when additional units are installed. For the ultimate conditions, when the district tributary is more densely populated, four pumps will be required, one of which will be a spare.

The lower compartment, containing the pumps, is encircled by two compartments, from one of which the pumps draw their suction, discharging into the other, which is connected by a force main to the gravity sewer at a higher level.

The upper compartment, or motor room, will eventually contain four vertical motors, four float switches, the switchboard, wash-stand, lockers for supplies, etc., and a venturi meter register. The sewage will be measured by a venturi tube situated in a chamber on the force main about 50 ft. from the pumping station, the pressure pipes being led back to the register in the motor room.

Power

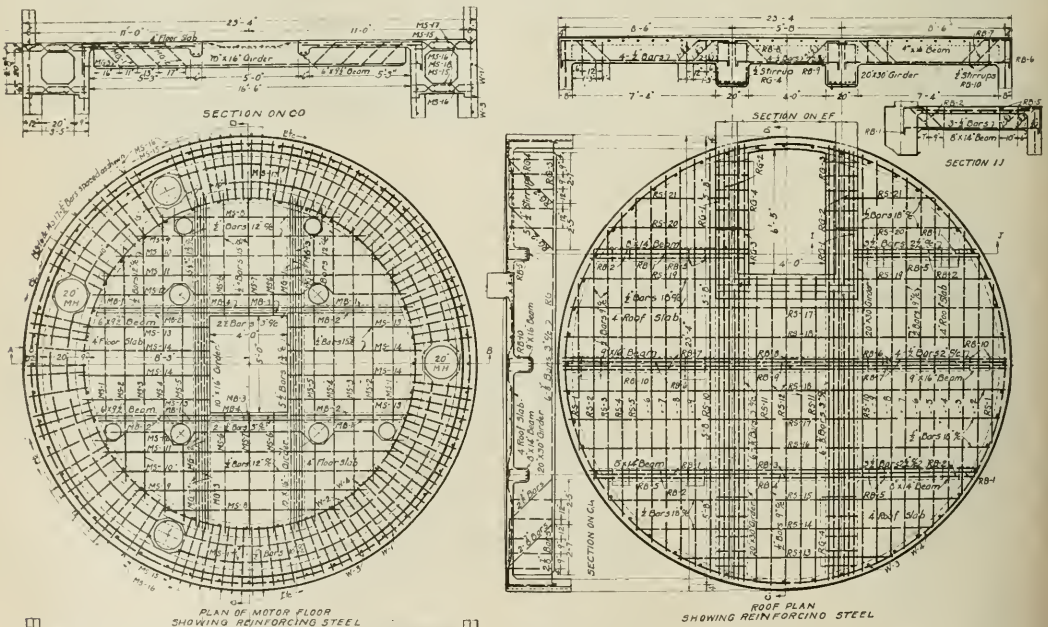
"Hydro" current will be used, and to provide for interruptions in current flow, 12-in. check valves are placed between the suction and discharge chambers, so that should the sewage rise to a sufficient height in the suction well, it would flow through the check valves and on into the force main with the minimum damage, if any, by flooding the interceptor and overflowing into the river.

Interior Finish

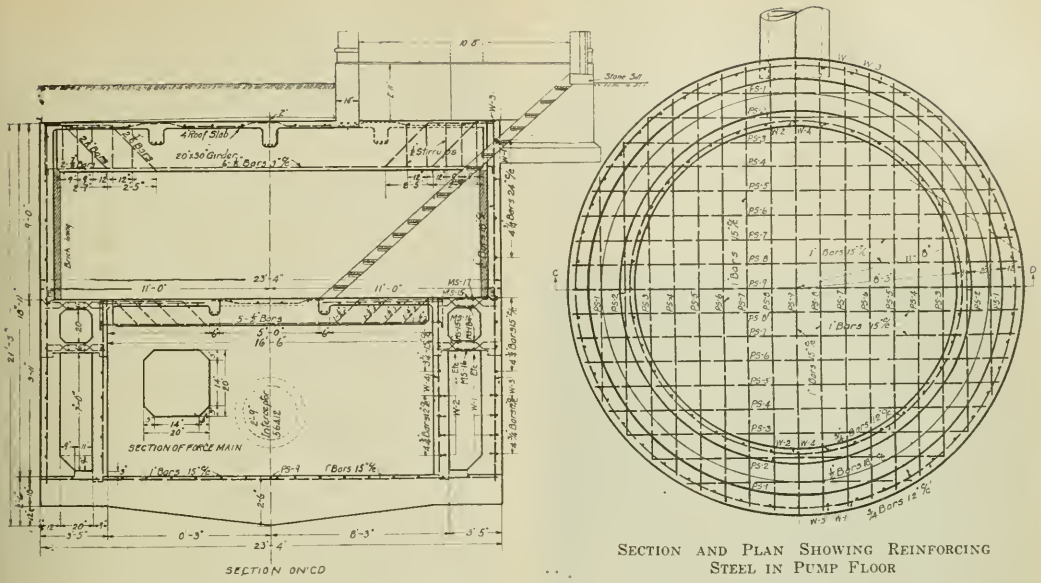
The motor room will be lined with a light-colored brick and will have a red quarry-tile floor. The ceiling and girders will be painted with a cream color cement paint. The pump-room will be painted a similar color, but will be a light stone color from the floor to a height of 3 ft. 6 ins.

Ventilation

A system of ventilation will be installed, capable of supplying 500 cu. ft. of air per minute, or a complete change of air in ten minutes. The fan with motor is placed near the roof, from which air ducts are carried to the floor of the motor and pump rooms. The air exhausted by the fan will be expelled through a flue and opening in the side of the superstructure, and fresh air will enter through the stairway



REINFORCING STEEL IN MOTOR FLOOR AND ROOF



SECTION AND PLAN SHOWING REINFORCING STEEL IN PUMP FLOOR

to take its place. This principle of ventilation, by exhausting the air from near the floor, was decided upon because gasoline vapors and other heavier-than-air gases, if encountered, would settle to the floor and require removal.

Waterproofing

The exterior of the pumping station, down to the level of the motor room floor, will be waterproofed with alternate layers of wool felt and coal tar applied hot. Over this, a 6-in. layer of gravel will be placed to drain the ground water from the top and the upper side walls of the station.

Superstructure

As the pumping station is located in a small park containing a bathing beach which is very popular in the summer time, it was deemed desirable to have the superstructure present a pleasing appearance. It will, therefore, be built of gray brick, with cut-stone trimmings, and will be covered with a copper-frame, wire-glass skylight.

Contractors and Personnel

The equipment was furnished by Darling Bros., Ltd., Toronto, and consists of Canadian General Electric motors, Sundh self-starters, Yoemans pumps and Yoemans float switches.

The pumping station is being constructed by the R. Wescott Co., Ltd., contractors, of Windsor, Ont., who are doing the excavation and concrete work at actual cost plus 15%, and the installation of pumping units and other equipment at a bid price. The total estimated cost, including two pumping units and engineering and contingencies, is $18,900.

The station was designed by Willard R. Rhoads under the direction of the writer, the firm of Morris Knowles, Ltd., being the engineers for the Essex Border Utilities Commission.

"BORE FOR POWER!" SAYS SIR CHAS. PARSONS

IN an address recently delivered in London, Eng., Hon. Sir Chas. A. Parsons, inventor of the Parsons turbine, said that "failing new and unexpected discoveries in science, such as the harnessing of the latent molecular and atomic energy in matter, the great position of England cannot be maintained for an indefinite period. At some time or other, more or less remote, the population will gradually migrate to those countries where the natural sources of energy are the most abundant."

England is using up its coal more rapidly than most other countries, and Sir Charles states that long before it reaches the point of exhaustion, it may pay England to import coal from countries where it is workable at lower cost. Ultimately water-power will be more rapidly developed, although the cost of harnessing all the water-power of the world would be about £8,000,000,000.

What shall England do to be saved from the disaster threatened by the exhaustion of its coal and the competition of other lands with plenty of cheap power? Sir Chas. Parsons' advice may be summed up in the one word: "Bore." There may be cheap power waiting, ready to be tapped, down deep in the crust of the earth, he says.

He recalled that some years ago he suggested boring a shaft 12 miles deep, or about 10 times deeper than any in existence. At that time the cost was estimated at £5,000,000, and the time that would be required at 85 years! Since then, he added, experiments have been made, showing that in limestone a depth of 15 miles is probably practicable, and in granite a depth of 30 miles might be reached.

"Little is at present known of the earth's interior," said Sir Charles. "When we consider that the estimated cost of sinking a shaft to a depth of 12 miles at present-day prices is not much more than the cost of one day of the war to Great Britain alone, the expense seems trivial compared with the possible knowledge that might be gained by an investigation into this unexplored region of the earth."

In Italy, at Lardarello, he said, bore holes have been sunk which discharge large volumes of high-pressure steam, which is used to generate about 10,000 h.p. by turbines. A similar project is on foot near Naples to supply power to the great works in that district.

Without promising that a 12-mile bore hole in England would yield ready-made steam-power, Sir Chas. Parsons urged that "the whole subject merits the most careful consideration."

TEST OF RIVERDALE PUMP, TORONTO

By T. M. Jones
Chief Engineer, The Bawden Pump Co., Ltd., Toronto

THE accompanying illustration (Fig. 1) shows a recent addition made to the equipment at the Riverdale Pumping Station, Toronto. This station is at the corner of Broadview and Carlton streets, and is so situated that all the water for the east end of the city is supplied through it. The consumption of water during a period of 24 hours varies considerably, the rate of pumping sometimes being as low

FIG. 1—RIVERDALE PUMPING UNIT, TORONTO

as two million gallons per day and at other times as high as five million per day, and, as one pump is called upon to take care of the supply, the city engineer had to select a pump having characteristics that would give high efficiency at a wide range of pumpage.

Besides high efficiency, other considerations were taken into account. Due to the fact that this station is situated

FIG. 2—EFFICIENCY, B.H.P. AND HEAD-GALLON CURVES

in a residential section, it was essential that the pumping equipment should operate with a minimum of noise. In view of the above local conditions and the variable pumpage required, both as to capacity and head, it was necessary for the contractors, the Bawden Pump Co., Ltd., Toronto, to design a special pump having characteristics that would meet the conditions with the maximum of efficiency. After careful investigation, they decided to install a 12-in. split-casing high-lift turbine-type pump, fitted with bronze impeller and direct-connected by flexible coupling to a 260-h.p., 750-r.p.m., 4,000-volt, 3-phase, 25-cycle, wound-rotor induction motor having resistance for 50% speed reduction, continuous duty.

The pump construction is of the most modern design, having a spiral casing, and is of the double-suction type, split horizontally so that shaft and impellers as well as bearing can be removed without breaking any pipe joints.

The switchboard panel is of blue Vermont marble, mounted on pipe supports, the instruments having a dull black finish, so that all parts of the entire equipment match one another, a very pleasing feature in a power-house where neat appearance is of some consequence.

This installation was completed about two months ago, and was recently given its official tests by the city's mechanical engineer. Fig. 2 shows the pump efficiency as well as head-gallon and brake horsepower curves at maximum speed, 735 r.p.m. Tests were made at twelve other speeds with equally good results.

The flow of water was measured by a pitometer, readings being taken at five-minute intervals, and in order to obtain the average flow of water in the discharge pipe, readings were taken at every inch across the pipe diameter. The suction and discharge pressures were taken by calibrated pressure gauges. The electric readings were obtained by a specially arranged set of testing instruments. The latter were also used to check the instruments supplied with the switchboard.

FLUSHING AND CLEANING WATER MAINS*

By William Molis
Superintendent Muscatine (Iowa) Water Works

NO matter how good the water is, what the source of supply, or how good the filters operate, you will find some accumulation of some sort in water mains—mud or a trace of iron or some algia forms—depending altogether on the source of supply—whether it is a deep-seated well, a shallow well or a large or small river. While the accumulation may not be large, and not detrimental to the health or purity of the water, it still exists, and the flushing of the mains will readily remove it.

One way of doing this is to gate off a main on both sides, say for half a mile, or a few blocks at one flushing, starting at some high point in the system, either by opening hydrants or a flush gate. If no flush gate is available, then start at the high point and open hydrants down the line until you get to the end. This procedure must be followed in the cross-sections, the same as in the main lines.

This flushing process is mostly done at night, when it will inconvenience the least number of people. In the outlying districts we usually flush mains in the daytime. One must have a good force of men on the job to be ready to answer a fire alarm and to open the gates quickly.

Flushing a 16-in. or larger main is not an easy task. A goodly number of hydrants must be opened to do the work right. If there are steamer connections on the hydrants, by opening these one gets a good flow and it is easier on the pavements.

We have two flush gates in our system, one a 6-in. and the other an 8-in. opening, which open into a large sewer or creek. I would not advise emptying into a sewer that is too small; all kinds of trouble will result from overflowing into cellars.

If there should be too much deposit to wash out at one time, there will surely be some trouble with the meters, which would then have to be cleaned out after the flushing.

*Paper read before the Iowa Section of the American Water Works Association, Mason City, Iowa, October 23rd, 1919.

THE AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS

THE twenty-fifth annual convention of the American Society for Municipal Improvements will be held November 11th to 14th, inclusive, at Hotel Grunewald, New Orleans, La. Among the papers and committee reports on the program are the following:—

Tuesday Afternoon, November 11th

"The Port of New Orleans," by J. Devereaux O'Reilly, chief engineer, Board of Port Commissioners, New Orleans.

Report of committee on Fire Prevention, Alcide Chausse, chairman, Montreal, Que.

Wednesday Morning, November 12th

Report of committee on Water Works and Water Supply, George G. Earl, chairman, New Orleans.

"The Sewerage, Water and Drainage Systems of New Orleans," by George G. Earl, general superintendent, sewerage and water board, New Orleans.

Report of committee on Sewerage and Sanitation, Frederick A. Dallyn, chairman, Toronto, Ont.

"Economic Values in Sewage and Sewage Sludge," by Raymond Wells, consulting chemist, Homer, N.Y.

"The Modern Grit Chamber," by George B. Gascoigne, sanitary engineer, sub-division of Sewage Disposal, Cleveland, O.

"Brooklyn, N.Y., Sewage Treatment Station: A Brief Review of Five Years' Work," by George T. Hammon, surgeon (Reserve) U.S. Public Health Service, Brooklyn, N.Y.

"Garbage Disposal and Economic Recovery of Valuable Constituents of Municipal Waste," by Samuel A. Greeley, Pearse & Greeley, consulting engineers, Chicago, Ill.

Report of committee on Street Cleaning, Refuse Disposal and Snow Removal, George H. Norton, chairman, Buffalo, N.Y

Wednesday Evening, November 12th

"Methods of Sewage Disposal Used by the Emergency Fleet Corporation," by Clark P. Collins, senior assistant engineer, Engineering Branch of Housing Department, U.S. Shipping Board, Emergency Fleet Corporation, Philadelphia, Pa.

"The Water Supply and Sanitation of Base Section No 1 (St. Nazaire, France)," by John B. Hawley, consulting engineer, Fort Worth, Tex.

"Army Camp Utilities," by W. L. Benham, Johnson & Benham, consulting engineers, Kansas City, Mo.

"Water Supply and Sewerage Systems of Camps Meade and McClellan," by Morris Knowles and John M. Rice, chief engineer and division engineer, Morris Knowles, Inc., consulting engineers, Pittsburg, Pa.

"The Acid Process of Sewage Treatment," by Edgar S. Dorr, engineer, Sewer Service Boston, Mass.

"The Psychological Influences of Public Improvements on the Minds of the People," by P. A. McCarthy, Lufkin, Tex.

"The Proposed National Department of Public Works," by W. B. Gregory, consulting engineer, Tulane University, New Orleans, La.

"Fairness in Specifications," by Alexander Potter, consulting engineer, New York.

Thursday Morning, November 13th

Report of committee on Street Paving, Sidewalks and Street Design, W. A. Howell, chairman, Newark, N.J.

"Proper Sands and Aggregates for Cement Concrete Roads," by Duff A. Abrams, professor-in-charge of Structural Materials Research Laboratory, Lewis Institute, Chicago, Ill.

"Recent Developments in Concrete Highway Construction," by A. N. Johnson, consulting highway engineer, Portland Cement Association, Chicago, Ill.

"Mineral Aggregates for Bituminous Pavements," by Wallace L. Caldwell, director of Department of Roads and Pavements, Pittsburg Testing Laboratory, Birmingham, Ala.

"Some New Discoveries in Bituminous Pavement Construction," by A. E. Schutte, consulting chemist, Warren Bros. Co., Boston, Mass.

"Roads in France and America," by Edgar A. Kingsley, consulting engineer, San Antonio, Tex.

Report of Committee on Standard Tests for Bituminous Materials, A. H. Blanchard, chairman, Ann Arbor, Mich.

"The Economy of Brick Street and Road Construction," by Will P. Blair, vice-president, National Paving Brick Manufacturers' Association, Cleveland, O.

"Vertical Fibre Brick Pavements," by Clark R. Mandigo, consulting engineer, Western Paving Brick Manufacturers' Association, Kansas City, Mo.

"Brick vs. Block for Permanent Street Paving," by S. Cameron Corson, engineer, Norristown, Pa.

Thursday Evening, November 13th

Report of committee on Street Lighting, C. W. Koiner, chairman, Pasadena, Cal.

"Illuminations, Ancient and Modern, with Special Reference to Decorative Street Lighting," by W. D'A. Ryan, director of General Electric Illuminating Engineering Laboratory, Schenectady, N.Y.

"Public Ownership of Utilities in Springfield," by Willis J. Spaulding, commissioner of Public Property, Springfield, Ill.

Reports of committees on Standard Specifications: Sheet Asphalt Pavement, Francis P. Smith, chairman, New York; Bituminous Macadam, Bituminous Concrete and Asphalt Block Pavements, Morris R. Sherrerd, chairman, Newark, N.J.; Broken Stone and Gravel Roads, With or Without Bituminous Surface Treatment, Arthur H. Blanchard, chairman, Ann Arbor, Mich.; Brick Pavements, E. H. Christ, chairman, Grand Rapids, Mich.; Cement Concrete Pavements, William A. Hansell, Jr., chairman, Atlanta, Ga.; Stone Block Pavements, H. H. Smith, chairman, Brooklyn, N.Y.; Wood Block Pavements, E. R. Dutton, chairman, Minneapolis, Minn.; Sidewalks and Curbs, Sylverius Sammelman, chairman, St. Louis, Mo.; Sewers, Alexander Potter, chairman, New York City; Foundations for Pavements, special committee, F. P. Smith, acting chairman.

Friday Morning, November 14th

Report of committee on Traffic and Transportation, on Uniform Traffic Laws and Classification of Highways, R. Keith Compton, chairman, Baltimore, Md.

"A National Highway System and Its Relation to Traffic and Transportation," by S. M. Williams, chairman, Highways Industries Association, and Federal Highway Council, Washington, D.C.

"Highway Traffic," by Frederic A. Reimer, county engineer, Newark, N.J.

Report of committee on City Planning, Nelson P. Lewis, chairman, New York.

Regional and Civic Planning as the Basis for Municipal Improvements," by Thomas Adams, housing and town planning adviser, Commission of Conservation, Ottawa, Ont.

"Lowland Farms Development, Youngstown, O.," by Morris Knowles, John M. Rice and E. O. Rose, Pittsburg, Pa.

"Architectural Design and Construction in St. Louis Parks," by Nelson Cunliff, commissioner of Parks and Recreation, St. Louis, Mo.

"The phenomenal development of highway transportation in the United States has created a demand for men having knowledge of and trained in a new technical field, which may be designated Highway Transport Engineering. Fundamentally, this branch of engineering deals with the science, art, economics and business of highway transportation of passengers and commodities. During the past decade, the United States has witnessed a rapid growth in the utilization of the motor vehicle as indicated by a registration of 125,000 motor vehicles in 1908 and 6,146,617 in 1918. While in 1908, a motor truck was rarely seen on American highways, in 1918 not less than 600,000 were in use in the United States, motor trucks constituting from ten to twenty per cent. of the registered motor vehicles in the several states."—A. H. Blanchard, Professor of Highway Engineering, University of Michigan, Ann Arbor, Mich.

THE UTILIZATION OF SEWAGE SLUDGE*

By John D. Watson
Birmingham, Eng.

REAL progress in the treatment of sewage sludge was made in Birmingham when it was first realized that (a) sewage was inoffensive to the sense of smell until putrefactive changes began, and (b) that foul-smelling sludge ceased to offend the olfactory nerves when putrefactive changes had run their course.

To bury sludge as it leaves the sedimentation tanks is to take the most efficient method of retaining the foul odor which characterized it when it left the tank. Sludge was unearthed at Saltley recently after 30 years, which proved that burial *per se*, even if the sludge is deposited near the surface of the ground, where nitrifying organisms are most active, is not sufficient to free it from objectionable smell.

With the idea of carrying on the functions of oxidizing the liquid of sewage and the septicization of sludge simultaneously, Dr. Imhoff patented about 1904, and in German fashion boomed, a two-story tank, which had the Travis hydrolytic tank for its prototype. The lower chamber of this tank is for fermentation, and the upper one for sedimentation. The Birmingham plan provides two separate shallow tanks, one placed alongside the other, to do the same work.

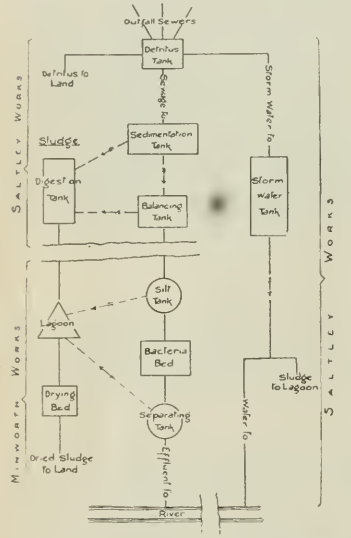

FIG. 1—DIAGRAM ILLUSTRATING METHOD OF PURIFYING BIRMINGHAM SEWAGE

In comparing the two, it is claimed for the Birmingham method that the cost of construction is less; it is better under control; the results obtained under normal conditions equally good, and under abnormal conditions—such as obtain in time of rainfall—much better. Operating costs of the Birmingham method are greater than by the Imhoff method, but the latter is distinctly inferior when large quantities of antiseptic substances like gas tar, arrive unheralded at the outfall works. It is desirable to isolate highly antiseptic matter instead of automatically distributing it over the whole surface of the fermentation chamber, or lower story of the Imhoff tank, where it tends to inhibit the action of the anaërobic organisms upon which the success of the process depends.

There are no doubt advantages and disadvantages based upon physical and topographical circumstances pertaining to both methods which an engineer must appraise in determining the design most suited to individual cases, but the author maintains that the shallow flat tank has more to commend it than the other, and in this view he is supported by the Drainage Board's consulting chemist, F. R. O'Shaughnessy, whose knowledge of this process is unsurpassed.

A marked feature of the Birmingham installation is the temporary character of the sludge digestion tanks, many of which are formed by a combination of excavation and embankment; the material employed to make the latter is composed chiefly of engine ashes laid on the soft material from the excavation. No lining of flag-stones or inside coating of any kind is given to these improvised tanks, the sludge itself having been sufficient to seal all the interstices of the ash embankments. These tanks or lagoons are sufficient to effect the main objects in view, but they do not admit of the advantages of quick and thorough emptying and refilling associated with well-built vertical-sided tanks. Still, when cheapness of construction is essential, as, for instance, when

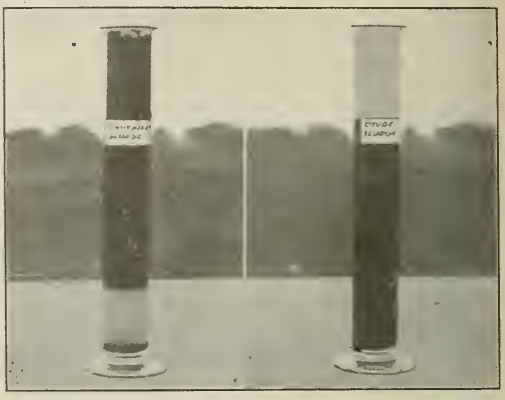

FIG. 2—FERMENTED SLUDGE FIG. 3—CRUDE SLUDGE

one is experimenting, this form of construction has much to commend it; indeed, if the Birmingham installation had had to be designed with the view of obtaining Local Government Board sanction to a loan, the probability is that it would never have been built, and the gigantic experiment which is about to be described would never have been made.

After the inflowing sewage from a population of about 750,000 persons passes through the detritus pit, from which the heavy solids are dredged by an electrically operated dredger, it flows through five sedimentation tanks working

FIG. 4—DRYING BEDS, SHOWING METHOD OF DRAINING

in parallel and subsequently through what is called a balancing tank. (See Fig. 1.) Each of the former has a capacity of slightly more than 1,000,000 gals., and the latter 7,000,000 gals., together 12,500,000 gals., or about half the dry-weather flow coming to this, the main outfall of the Drainage Board's Main Sewerage District. Each of the 5,000,000-gal. sedimentation tanks is cleaned every week, and the balancing tank, which is run in series with them, less frequently.

*Paper presented at the 46th annual meeting of the Institution of Municipal and County Engineers of Great Britain.

The crude sludge—92.5% water—arrested in the Saltley sedimentation tanks alone amounted to 1,523,000 cu. yds. during the past four years, or an average of 380,750 cu. yds. per annum, the whole of which was transferred to 39 sludge digestion tanks or lagoons possessing a total capacity equal to 28,250,000 gals.

The total *dry solid matter* removed from all tanks at Saltley, etc., Outfalls, including Minworth Tanks, in the four years 1915-18, amounted to 110,000 tons, or 75 tons per diem, all of which was transferred to the sludge digestion lagoons.

The density of the sludge removed chiefly depends on the frequency of the cleaning operation. During 1915 these tanks were emptied once in two or three weeks, when the average water content of the sludge was 87%, whereas the weekly cleaning during the four years under consideration yielded sludge with a water content of about 92.5%.

Theoretically, the more frequent the emptying operations the better, but economy suggests a curtailment of the operation when temperatures are low. When temperatures are high, there should be frequent cleaning, and the strictest avoidance of obstructions in the sewers should be encouraged if objectionable odor is to be reduced to a minimum. This becomes even more imperative as the area of a drainage district increases.

It has been shown that with care the putrefaction of the liquid can be prevented, but the successful digestion of the sludge has proved to be a more difficult problem; still, with accumulated experience and the expansion of the tank area, the operations at Birmingham have been conducted with greater ease, economy and success as time went on.

The digestion tanks used at first consisted of an existing installation of 20 tanks, 16 of them with an aggregate capacity of 4,539,500 gals., and 4 of them with an aggregate capacity of 2,723,680 gals., all so thoroughly well built and equipped with emptying arrangements that they are easily the best of the installation of 39 tanks.

For the first two years the digestion operations were conducted in two stages in this installation of 20 tanks. The 16 tanks were used for primary digestion and the 4 larger ones for the secondary digestion. Two stages were adopted, as it was found in the very early days that vigorous fermentation was the better maintained thereby and tank space was saved to such an extent by pumping from one tank to another that the second pumping was economical when compared with the prospect of an increased capacity; it was soon discovered also that inoculating raw sludge with ripe sludge thus obtained from the secondary tanks had an excellent effect upon the "speeding-up" process. Further, temperature was too obviously a beneficial factor in the success of the process to be ignored.

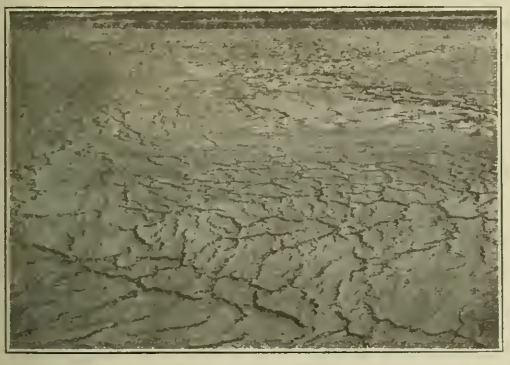

FIG. 5—SLUDGE AFTER IT HAS BEEN IN THE DRYING BED FOR THREE DAYS

The following mode of operation was adopted at the beginning of 1912 and has been continued ever since:—

In cold weather the sludge is transferred from the particular sedimentation tank whose turn it is to be cleaned out, into the selected digestion tanks (generally five or six in number) by the main set of pumps; simultaneously some of the ripest of the available sludge is pumped by a small pump into the same delivery main in the proportion of 1 to 4, thus inoculating at the earliest possible moment the fresh sludge with the fermentative organisms; in addition, steam from one of the Lancashire boilers is injected into the delivery main to produce temperature conditions most favorable to fermentation.

In moderately warm weather steam injection is abandoned, and during the heat of summer neither inoculation nor steam injection are resorted to. The biological factor governing the digestion process must necessarily be somewhat complicated, and it is only by the most careful observation of the conditions which bring about the right balance of living organisms that success can be achieved.

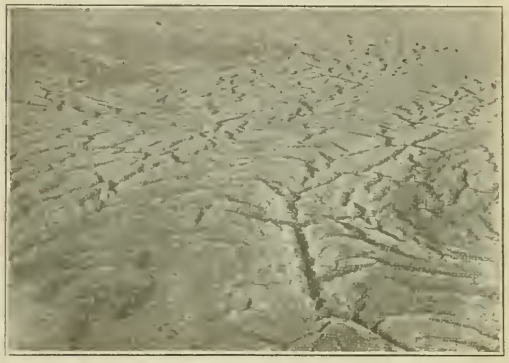

FIG. 6—SLUDGE AFTER IT HAS BEEN IN THE DRYING BED FOR THIRTEEN DAYS

The following tables of analyses supplied by Mr. O'Shaughnessy indicate two different sets of conditions, Table A where the fermenting mass was very offensive, and Table B where the vigorous fermenting mass was quite inoffensive:—

TABLE A.

		Total counts. Organisms per cc.
Gelatin-Peptone-Bouillon at 20°C.	Mean	24,000
Agar-Peptone-Bouillon at 37°C.	"	130,000,000
Coli group		7,000
Proteus group (including *Enteritidis sporogenes*)		100,000
Denitrifiers		500
Fat-splitting organisms		10,000
Cellulose		100,000

TABLE B.

	Total counts. Aërobic per cc.	Anaërobic per cc.
G.P.B. at 20°C.	52,000,000	15,700,000
A.P.B. at 37°C.	5,000,000	3,000,000
Coli group	60,000	
Proteus group	100,000 at least	
Denitrifiers	100,000 "	
Fat-splitting organisms	100,000 "	
Cellulose organisms	50,000	

Having obtained the right bacterial balance, so to speak, the aim of the management is to maintain it. What looks like an inexhaustible volume of sludge which constantly varies in character (about 1,000 tons per day) is drawn to a locality literally surrounded with dwelling-houses, factories, etc., and formerly gave rise to loud and serious complaints. Now, this large mass of foul material is treated on the same site without any offence whatever.

Variation in the character of sludge is only to be looked for in a great manufacturing district where there are no restrictions on the discharge of trade waste into sewers; but these are sometimes very serious in their consequences, as when large discharges of tarry products from coal, water, or producer gas-plants suddenly appear.

The saving factor in the situation is the system of separate sedimentation and separate sludge-digestion tanks, so that whether it is a sudden increase of volume due to rainfall or an overpowering mixture of antiseptics, the large number of sludge tanks in all states of fermentation renders the scheme at once elastic and manageable. The capacity of the whole of the sludge-digestion apparatus is equal to 165,000 cu. yds., or 28,000,000 gals., which, with the present demand, means a time retention of between four and five months.

FIG. 7—FIVE TIP WAGONS DRAWN BY ELECTRIC BATTERY LOCOMOTIVE

The average analysis of the sludge for the four years 1915-18 is as follows:—

Water	92.5	%
Dry solid matter	7.5	%
Specific gravity of wet sludge (estimated)	1.0256	%
Specific gravity dry solid matter	1.50	%

The average analysis of the dry solid matter is as follows:—

Matter volatile at red heat	58.5	%
Matter non-volatile	41.5	%
Total nitrogen	2.71	%

The fatty matter in the crude sludge varies greatly, the actual limits for the figures in the analyses made being from 16.86% to 31%, with an average of 22%. These figures represent a total ether extract, but it is probable that about 2% of this ether extract is resinous matter, and the real fatty matter will be represented by an average figure of about 20%.

Those who see the Birmingham works for the first time are struck by the great distance (about five miles) which separates the sedimentation tanks from the bacteria and sludge-drying beds. In contemplating this it should be remembered that the Saltley section of the Board's works was built more than 60 years ago.

The author is responsible for selecting Minworth as the site of the main works, and the reasons were:—

1. The advisability of obtaining as isolated a site as possible where it would be practicable to have the whole of the works some day.

2. The belief which obtained 20 years ago that a 24-hr. period of septic action was beneficial, and that utilizing the capacity of the existing 8-ft. conduit (6,000,000 gals.) would obviate the need for increasing the tank capacity at Saltley.

3. The fact that the disparity between the falling gradient of the conduit, 2 ft. per mile, and the river, 7½ ft. per mile, provided an available head of 29 ft. with which to spray the sewage over the bacteria beds and eject the sludge from the silt tanks.

Minworth was also selected as the best site for completing the fermentation process of sludge treatment and laying out the drying beds. This involved pumping from Saltley, a distance of five miles—a task which looked more formidable than it turned out to be, the sludge in its fermented state having been found to be more mobile than was expected, a condition due probably to the innumerable air-bubbles between particles acting upon it as so many ball-bearings. This is illustrated to some extent by the photograph of the glass cylinder (Fig. 2), which shows fermented sludge, after a short settlement, held up by the air-globules *above* the clear water. Fig. 3 shows the crude unfermented sludge in a similar glass cylinder with the liquid above the solids.

The improvised lagoons at Minworth, which form part of the installation of 39 tanks, were formed by surplus spoil from the bacteria bed site and dry sludge from the drying bed area, and they perform at least three functions:—

(a) They give time for the completion of the fermentation process.

(b) They permit, with almost no detriment to the installation, the admission of humus from the bacteria beds, flushings from tanks and flushings from distributing pipes.

(c) They act as decanters of supernatant water.

The first is of course the primary purpose of the lagoon.

Imhoff found that he required his fermentation chambers to be large enough to contain from three to six months' storage of sludge. The author finds that the average requirement for the past four years has been equal to a storage of four months.

It has been proved abundantly that sludge dries more readily when the digestive process has been carried to exhaustion before it is pumped to the drying area; hence the economy of ample tankage.

The second is a most important function. The so-called "humus" excreted from a bacteria bed, like the sludge discharged from an activated sludge plant, is a valuable fertilizer, but so far has not been utilized because of its "emulsive" character and the difficulty and expense of dewatering.

FIG. 8—FILLING WAGONS WITH DRY SLUDGE

When nearly 1,000 tons of it have to be got rid of each day, the importance of dewatering cannot be over-estimated. To pump it back to the beginning of the process (the detritus pit) is a practicable solution in most cases, but not when it has to be forced through five miles of pumping main. Mixing it with the sewage as it entered the silt tanks just before spraying it over the bacteria beds was tried, but was found impracticable owing to the fibrous growths which were introduced into the distributors. Allotting a lagoon to itself with the view of trying to separate solids from liquids

(Continued on page 427)

RECONSTRUCTION AND CIVIC DEVELOPMENT*

What We Have Learned from the War and What We Can Take from Europe—"Co-operation" the Slogan for the Reconstruction Period

By C. H. Mitchell, c.b., c.m.g., d.s.o.
Dean of the Faculty of Applied Science and Engineering, University of Toronto

We have learned a great deal by the war. We have learned a great deal in adjusting our ideas so that on coming back home we may reapply them in Canada. We who are engaged in construction, whether material or educative or moral, are confronted with many problems, and what our soldiers have learned in Europe can readily be applied here, to the best advantage, to the new conditions under which we now find ourselves.

For those of us who are engaged in construction and in art, civic development, town planning, architecture, etc., what more do we want in the way of inspiration than some of the things that all of us saw, for instance, in that sacred city of Ypres, with its wonderful architecture, its features of what old-world planning meant 400 years ago, and, by contrast, what it may mean now: the beautiful architecture of the Cloth Hall and St. Martin's Cathedral, and the old walls and the moat, the wonderful old gates, the Menin Gate and the Lille Gate. All these things must have an influence on those who have come back.

Impressions from Italy

In the same way, in my own experience, I cannot help feeling that my year and some months in Italy were full of memories which will influence my life and views for many years to come. When we first went to Italy, now almost two years ago, we were confronted with many problems in which civic development and town planning had a very material part. The little city of Mantua, which you all know from Shakespeare if in no other way, had, to me at any rate, a particular interest because of the extraordinary arterial traffic arrangements in narrow, crowded streets, with arcades along them, and in which the traffic conditions were very serious.

No one would ever have thought of them as being serious if we had not tried to march one division after another toward the front, through those narrow streets. I shall never forget the day when the First British Division marched through Mantua, going toward the front, November 19th, two years ago, when the enthusiasm of the Italians knew no bounds. Brigade after brigade of infantry and artillery and transport marched through that little old city, with its narrow streets resounding with the clank of wheels, and the whole populace out on the streets or wherever they could get—on the verandas or on the galleries or in the windows—shouting, cheering, singing, waving everything from handkerchiefs to table cloths, and throwing flowers and fruit to the soldiers continuously for hours at a time. It was a wonderfully inspiring thing, and that same spirit followed the British all through that campaign to the end, and when we came out of Italy the Italians were the same firm friends of the British that they had always been.

An Axiom and an Example

And Venice! I well remember standing in Venice a year ago, after the armistice, and comparing Venice then with the Venice of 12 years ago, when I saw it before, and trying to realize what the war had meant to that city. Venice was not close enough to the front, even after the terrible catastrophe of Caporetto, to be shelled, although a few shells were dropped near it; but it was close enough to the front to be almost continuously bombed by the Austrian airmen.

It is surprising how many bombs can be dropped into a city without doing much damage, and it is surprising how little damage of a serious character really was done. You will all be glad to know that the damage to Venice was comparatively small.

With regard to the war generally, we have been in the business of destruction, and now we are confronted with the business of reconstruction, and with that goes all the development that we have learned from Europe. But the situation and the conditions in which we have to apply this, determine the progress that we can make. That is another axiom, of course, which is ever before those engaged in civic development and town planning. But of those things, what are we going to select? Along what lines are we going to develop? I cannot refrain from quoting a thing written by Kipling,

> "When 'Omer smote his bloomin' lyre
> "He'd 'eard men sing by land and sea,
> "And what he thought he might require
> "He went and took, the same as me."

Now it is for us to go and take, and what we can take and apply in Canada are the things with which we are most vitally concerned to-day.

What Can We Take?

What can we take? The science and the art of town planning—I am speaking now in the broadest sense, and it is not confined to town planning but applies to civic development, and national development if you like—is based on three principal things. The first is the collection and the investigation of information and data. After all, I suppose that is the same kind of job as I had in the war, which was the collection of information, only it was about the enemy. I feel strangely familiar with those expressions. Next after that comes the analysis of that information; and after all, I suppose that is a bit of intelligence work too. And thirdly, the conclusions we make from that analysis, and their application. Those are the things with which we are now concerned.

In general, there are two large branches into which these resolve. One is the branch of education, the informing of the public as well as ourselves, and the improvement of our minds, with regard to the science and the art of civic development, based upon all those things which we have brought from Europe and of which we have read. Then comes, arising from that, the application: The legislation, which, through the means of good government, we are able to bring about, by that means forming a stimulus by which to raise the standards of life.

Roads and Transportation

Let us see what, of these things which we have been able to learn from the war, we may apply in this country. Take, for instance, the question of roads and streets. I do not want to be too specific, but those of us who have been "over there" realize what good roads and streets, the proper kinds of streets for definite purposes, mean. Those of us who were driven along the great pavé roads of northern France, realized then, and we realize more now, when we have come back to this country, what Napoleon meant when he said that roads won wars. I do not suppose there has ever been a finer example of that axiom than in this war, for I am sure, as you must have heard dozens and dozens of times, that the war could not have been fought in Flanders were it not for the good pavé roads that Napoleon's engineers built 100 years ago. Not that we anticipate ever having a war in this country, but we are engaged in a war of peace, a war of industry and a war of many other things, by contrast, which require good roads. Now let us start out to get good roads and good streets built for the purpose.

Another phase is transportation as apart from the material road itself. When I got back to Canada, landed at Montreal and a few days later arrived at Toronto, I was struck with the tremendous change that had come about in our civic situation by the very general use of the motor car. We thought, over in France, and in Italy, too, that we had nearly all the motor cars of every kind and vintage that could be scraped together into one place. When we got back to England, on leave or after the war was finished, we dis-

*Excerpts from a luncheon address before the Canadian Club of Ottawa, Ont., during the joint conference held October 18th-19th by the Town Planning Institute of Canada, and the American City Planning Institute.

covered, as we thought, that probably most of the cars came from there, because there were comparatively few in England. But when we got back to Canada and saw them parked for miles on the streets of Montreal and Toronto, we realized that, after all, all the motor cars in the world had not been sent to the war; and we realized also what it means to introduce a new form of transportation that is going to revolutionize the whole business of civics.

Aeroplane Photography

A means of study which the war has developed, and which perhaps we who are engaged in civics and in other lines of work can naturally use to good advantage now, is aeroplane photography. I saw hundreds of photographs of towns in France and Belgium, and in Italy, too, not only on our own side—we took very few, of course, on our own side—but also on the side occupied by the enemy, and I could not but realize what a great advantage it is to have the means of getting an aeroplane photograph of a place in order to pick out the essential, outstanding features. It seems to me that if I were a gentleman engaged in town planning, I would want to own an aeroplane in order to take photographs before and after, and in order to make studies of how to replan and how to work out schemes.

You probably remember the use to which aeroplane photography was put recently in connection with excavations in Persia, and which someone out there discovered, I suppose, by accident. Some persons who were looking for the ruins of a lost city were able by an aeroplane photograph, taken high up, to discern underneath the sands, by some difference of color or shading, or some features about the sands, the outlines of the city for which they were seeking,—by the same method by which an aeroplane or a balloon can always see a submarine deep down in the water. It is a most curious application of aeroplane photography, but I am sure of this, that many other things will be found about this device which can be applied to much of our work in the future.

One of the first requisites in our reconstruction is education. Not only in the science and art of town planning and civic development, but in many other things, our country requires education: that publicity which comes through the press and otherwise; that real, genuine, basic information which comes through the school children themselves in the public schools, and which, as many of you know, is being applied with such great success in Chicago; and the education in connection with our universities.

Four Hundred Freshmen

The Faculty of Applied Science at the University of Toronto now has many more students than in the greatest year before the war. There are over 800 students, of whom 400 are freshmen. As announced yesterday, we are hoping to put on a course, and some work in design, etc., in connection with civics and town planning, and that, we hope, will be something towards education for the country in connection with this work.

In Canada, and in fact all over this continent, we have come now to the industrial age, and with industry, as we see it now, and as we saw it during the war, the great essential is to produce. To produce more we must introduce methods and means whereby the people can live more comfortably and earn their money more easily, and go back and forth to and from their work more readily, particularly as industries are developing far out from the crowded portions of the cities. And at the same time, we must realize that our duty is to do something by which the earnings can be more equitably distributed for the convenience of everyone. That I do not wish to discuss further except to say that we should realize that the industrial situation is closely bound up with general civic development and the broad subject of city and town planning.

If we look at the great successes of industry and science, not only during the war, but for centuries before, we find that they are the evolution of many minds, the evolution of many years, the evolution of many processes and experiments, some of which have been great failures, others of which have been successful in the sequence by which they have come. To them we look for examples by which we can apply our future methods of civic development and our future methods of civic planning. I am speaking now not only of the actual planning, but of the economic side and of government as well.

The methods by which this can ultimately be brought about will be identical with the methods by which the evolution of anything in history has been achieved, such as the steam engine, or such as, in the war, the tank. A few weeks ago an effort was made to determine who invented the tank. Well, of course, no one man invented it. Eleven claimants came forward to the Inventions Board to say that they had invented it, and the next day, not after a long period of investigation, it was discovered, and announced by Winston Churchill, that no one man invented it; that to the whole eleven belonged the glory of the achievement. And the same thing is going to apply in civic development and civic planning of all kinds. Everybody is in it and everybody is doing it, and the thing is to have it go hand in glove with all the other development and reconstruction work in which we in this country are embarked.

The Scientist Comes First

And in that development the scientist must be the first man to do his part—to do the part which will bring about the analysis and the investigation of all these things, and the first trials which are made; and after that, so far as town planning is concerned, the aesthetic side, the artistic side, comes into consideration. But do not let us try, as I fear we in Toronto for a long time tried, to have the artist the first on the ground, and then to consider the practical or the scientific side in the second place. It should be the other way round.

With regard to legislation, just a word. That is the other element with which we have to deal, and which, I am sure, everyone is thinking about a great deal at the present time. The duty of those responsible for legislation is primarily to raise the standards of human life. I think everybody will agree to that. And whatever we do for reconstruction, that must be the thing in front of us, clearly defined all the time; to make the country a better place in which to live and work; to make the lot of those who work, happier and more contented—because you cannot get really good work out of discontented people, and with discontented people you cannot get health and ease. Lloyd George once said: "You cannot make an A1 nation out of a C3 lot of people." That applies just as much now, when we are at peace, as it did when we were at war. Now we have come to the period when legislation is required; more legislation; not too much of it. I am afraid we have too much of it now in some respects.

Another thing which Lloyd George said:—"Society and the nation at large, at the present time, is in the molten state, and in that molten state you can impress or stamp anything on it that you will, so long as it is reasonable." Now is the time to put the stamp on it, and let us do so in civic development.

Education, Legislation and Co-operation

Following on these two, education on the one hand, legislation on the other, comes the other thing, co-operation. Co-operation won the war, and we cannot say it too loudly in this country at the present time. Those of us who were at the front know what co-operation meant among the various arms of the service. Those of the infantry know what it meant to have co-operation from the artillery, shooting over them, carrying them, with its barrage in front of them, up to the enemy's position. Infantry and artillery both know what it meant to have the co-operation of the engineers, who were preparing in various ways to help them across. They all realized what it meant to have the co-operation of the men in the air, who were observing for them, directing operations so far as information was concerned, and performing all the work which men in the air could do. And behind it all there was the co-operation of all the various organizations and the staffs all the way back to the army staff, 20 miles behind the line. That was co-operation, and it all fitted into one plan; and the more we worked at it, the more we tried, the more we developed it and the better the co-operation, the better we succeeded and the more we won.

Now we have come back to the wars of peace, and co-operation is the watchword. We must have co-operation from everybody in the scheme of the country, from the top down, from inside and out, from all classes of people—everybody trying to help everybody else; and in no place can we apply it more advantageously and more successfully than in this very large problem of civic development. I am sure that in the construction period that we are entering on now, with the public mind not settled on these things, the leaders of all civic improvement and civic development must take their position to lead and to impress and to engage in that co-operation all classes of people.

People say right away, if we start talking about large programs—and I am afraid that very large programs are talked of—that money is the first requirement. Well, money may be; but there are many things that can be done even without a large amount of money, and it is for those of us engaged in this work to think out what we can do, for the present at any rate, until such time as money is forthcoming to do it, and therein to adjust our views to the requirements of the country for the future. But again it is co-operation.

In the same way, policies of all kinds are advanced—good and bad, reasonable and unreasonable—policies which are nebulous and policies which are perhaps too specific; but all of these require careful thought and discussion and education and publicity, and the co-operation of everybody, from the top down, in order that we may determine what policy to follow. And in the end, everything from the group to the community, and the regional area, and the nation, and all things which involve housing, transportation, public utilities, education, etc.—all of these things fit together, so that in a large way the word "co-operation" spells success. The great motto, after the war and for the period of reconstruction, is "co-operation."

PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSING OF TURBINE GATES*

By J. T. Noble Anderson

On several occasions, the writer has investigated this question, or a cognate phenomenon, with pumps—centrifugal and others—through long pipes. In one case, there were two pipes with a common penstock—each of wood, 3 ft. in diameter, and 2,300 ft. long. In every case, he has been greatly impressed by the extreme complexity of the subject.

With the help of Prof. Joukovsky's theory and some "rule-of-thumb" guesses, gained from a general experience, these pipe lines and the values concerned can now be calculated to as close an economic margin as most other engineering problems. At the same time, the result of experience shows so many baffling discrepancies, that the experimental results, which Mr. Gibson hopes to obtain "in the not too distant future," will be waited for eagerly.

The care he has taken to collect and co-ordinate the formulas, is an earnest that he may be relied on to record fairly and fully not only his results, but all the extraneous facts and happenings which may, however, remotely, bear on the many irregularities between actual records and what the formulas anticipate. In particular, it might help if two slightly disturbing factors were recorded in each test, that is: (1) The temperature of the water; and (2) the proportion of free air present in the water.

The second factor will probably be quite immaterial, but, in a case where the substance pumped through a centrifugal was sewage with a specific gravity of 64 lbs. per cu. ft., the author found that the gases contained had a very disturbing influence.

In some recent investigations, the writer used a steam indicator with springs specially chosen for the anticipated pressure. Some indication of Mr. Gibson's apparatus will no doubt be given.

*Discussion (presented to the American Society of Civil Engineers) of Norman R. Gibson's paper (see September 4th and 11th issues of *The Canadian Engineer*).

LOT AND BLOCK UNITS FOR HOMES OF MODERATE PRICE*

By Arthur Coleman Comey
City Planner, Cambridge, Mass.

It is to be assumed that in the normal case a proper layout of main streets and disposition of public grounds will permit the minor streets to be so arranged as to produce the optimum in block lengths and widths, the latter closely affecting lot depths. Lot widths on the other hand are not controlled to any large degree by other elements in the plan and may, of course, readily be changed at any subsequent time prior to development or actual sales without materially modifying its general relations.

Factors Controlling Width

The factors controlling the width of interior lots are, on the one hand, adequate width for the dwelling itself, light and air in its yards and (to a less degree) passage for automobiles; on the other, the cost of utilities in the street, which rise rapidly as lot widths are increased and practically require the minimum adequate width to be the standard, if not the maximum as well, except as topography and other elements in the plan fix certain points and permit somewhat larger lots without increased expense. A house nearly square is the most economical, so that, except where under the spur of high land values lots have been plotted too narrow, the two room deep house is the usual type.

For detached houses, 7 or 8 ft. is the minimum side yard width to assure sufficient light and air at the first story, as well as safety from fire. One side yard should be at least 10 ft. wide to provide space to drive an automobile. The square house is probably the widest that should normally be provided for. The 6-room house may be as small as 22 ft. square, the 7 and 8-room types running up to 26 or 27 ft. The proper standard minimum lot width for detached houses is 40 to 44 ft. Unless 40 ft. can be obtained, semi-detached or row houses should be planned.

For semi-detached houses, 10 ft. is none too wide a side yard for light and air as well as for the passage of automobiles. Such houses need not be over 23 ft. wide and are frequently not over 20 ft. The proper standard minimum lot width for semi-detached houses is 30 to 33 ft. In sections with moderate rentals it is proper to mix detached and semi-detached houses according to any scheme of grouping the city planner and architect may work out. Each pair of semi-detached houses requires 1½ lots of a size suitable for detached houses. In cases, therefore, where it is desirable to plat lots in advance of building, the 40-ft. width, or better, 44 ft., may be used as a standard minimum.

Mingling of Types Undesirable

Three reasons prevent the advantageous mingling of row houses with the other two types: An alley is usually required behind the row house, a considerable expense, which constitutes an unnecessary burden if incurred behind houses with side yards and therefore not dependent on alleys; the larger building units are apt to be out of scale with the other types; and in most cases the type of occupancy is different. The row of three houses placed at intersecting streets may be used with semi-detached and detached houses by adding to the rear yard of the middle house an extension 10 to 20 ft. wide, reaching the side street across the rear of the corner lot. The unit of three will require about two lots of the size for detached houses, and therefore fits into a scheme of 40 to 44-ft. lots.

The row house attains practically its full economy with 5, 6 or 7 in a group. Above 9 the inordinate length of the row becomes unpleasant architecturally, and at the same time increases fire risk and steadily decreases ventilation in the block. Such relatively short groups obviously require special lotting. The lot widths for interior houses are controlled absolutely by the design of the house. To secure

*Paper read October 19th in Ottawa, Ont., at the joint meeting of the Town Planning Institute of Canada and the American City Planning Institute.

adequate light and air, row houses should not be more than two rooms deep. The usual plan is one large room across the front and one or two smaller rooms at the back. The proper width for such a house is 18 or 20 ft. The end houses of rows may be put on lots 27 to 30 ft. wide, so that two such end houses of adjacent groups require three of the lots designed for interior houses.

It is difficult to make a lotting scheme which will serve for both row houses and for semi-detached and detached houses. In cases where row houses are anticipated, lotting should accompany the plan for grouping the dwellings instead of preceding it.

Expense is in Frontage

While it is generally recognized that 50 ft. is sufficient distance for light and air between the fronts of small houses, and while this same distance is also a sufficient minimum between backs, in practise such shallow lots as these dimensions produce are seldom found necessary owing to the fact that added lot depth does not correspondingly increase the cost of most utilities. It is frontage that is expensive, and rear land must be considered to remain close to the acreage cost of raw land. This is a particularly important factor where topographical conditions or irregular boundaries would involve considerable extra length of streets to produce but few more lots of standard depth, the alternative of fewer and deeper lots with much less street construction being much cheaper and involving only a slight loss in gross selling value.

On all except the main thoroughfares, the needs of traffic are not sufficient to affect the distance between the fronts of houses. In detached house neighborhoods, experience indicates that 20-ft. front yards are not excessive. For semi-detached houses, 15 ft. is found suitable. For row houses, 10 to 15 ft. may usually be provided. A variation in set back not exceeding 5 ft. usually adds to the attractiveness of the street. Unnecessary depth runs up the cost of service lines from the utilities that are placed in the street. If the street line were placed at the building line, as in Washington, D.C., the utility lines might be run close to the houses, thereby saving considerable expenditure necessary under any of the present methods.

Houses of moderate price normally range from 18 to 32 ft. in depth, the vast majority being from 20 to 30 ft. deep, though certain designs for narrow semi-detached houses may require 34 to 35 ft. In the depth of rear yards even more variation occurs, both because their use varies and because it frequently proves to add so little to the cost to make them ample. For detached houses, an ample garden space for a person working elsewhere during the day is 40 by 50 ft. If not so used, this is still not too large for children's play.

On streets of ordinary width, lots for detached houses should normally be planned 90 to 110 ft. deep; for semi-detached houses, 80 to 100 ft.; and for row houses, 70 to 90 ft., including to the centre of alleys where introduced.

Where extreme land values do not preclude, a scheme of lots based on a standard minimum of 40 to 44 ft. by 90 to 100 ft. is proper. In extreme cases, where row houses are certain to come, lots as small as 16 to 18 ft. by 70 ft. may be necessary, but intermediate widths so common in most of our cities are not easily adapted to modern housing standards.

Corners are Special Problems

The best size for corner lots in cases where practically all the houses are to face one set of roughly parallel streets may be fixed as ranging from the same width to 5 ft. wider than corresponding interior lots, and approximately the same depth.

With houses fronting on all streets, to secure the maximum salable frontage and the least interruption to the architectural motive along each street and around the corner, the corner lot is best made approximately square. It should be equal in area to the corresponding interior lots. A somewhat large square corner lot may be cut diagonally in two, and a pair of semi-detached houses set across it, though this expedient is not always pleasant. It is not apt to be a good plan to attempt to crowd houses at a street intersection and still give sufficient square feet of rear yard space by violent skewing or irregularity in lot boundaries. Acute interior lot corners should be particularly avoided. Lot lines should usually be run back at least 40 ft. to a point not less than 5 ft. behind the house, approximately at right angles to the street.

Block widths are normally twice lot depths, though many irregular blocks are bound to be platted, especially in layouts on rough or peculiarly shaped land, to economize in construction cost and in land used for streets.

Block lengths are controlled by the needs of traffic, both vehicular and pedestrian, and by factors of safety. Experience shows that in residential areas, blocks 600 to 700 ft. long cause little dissatisfaction. Shorter blocks are wasteful of land in cross streets. Blocks longer than 800 ft. are found to cause undue detours in going from one side to the other. This is more noticeable in the case of foot traffic than the modern automobile. Inasmuch as adequate footways require but one-sixth the space of cross streets, and even less proportionate construction cost, their use midway across blocks of lengths up to 1,200 ft. is permissible, particularly in districts with steep slopes, making connecting streets expensive. In areas designed with deep courts and blind streets only partially cutting up the blocks, if each such court and street has a path leading from it across the block, most of its disadvantages will disappear, though it will still be less easily policed or protected in case of fire than regular blocks.

While variations to the ordinary block and lot system which do not easily conform to rule have hitherto seldom been laid out, the increased attractiveness attending their use in a reasonable number of instances demands that the opportunity be not closed by rigid standards. As they are apt to be integral parts of the group designs for the actual houses, their layout cannot be determined until the building program is adopted. Where interesting variations are not anticipated, the minimum standard of blocks, 180 to 200 ft. by 600 to 800 ft., with lots 40 to 44 ft. wide, is more apt than any other to be adapted to the future needs of a neighborhood.

THE NEW MUNICIPAL STANDARD

VERY illuminating is the story of two Ohio cities told by the State Department of Health. These cities are Wellsville and Ironton, with the unenviable distinction of having as many cases of typhoid fever in five months as two score of larger cities of the state had in the same period. Speaking exactly, these cities had 51 cases, while 80 remaining cities had 180 cases during the same period. Reduced to averages, while Ironton and Wellsville had an average of 25 cases each in five months, other cities had an average of three each. Ironton is now taking steps to remedy its defective water supply and citizens of Wellsville are waking up to past dereliction. Consumption of untreated Ohio river water is not consistent with municipal health. When both cities have completed their works they will soon lose the sorry reputation which they have gained in this vital health respect. Looking at the matter in its broader phases there is an interesting field for study opened here. Let comparisons be made among remaining cities of the state. The success of local municipal government may be told with greater accuracy in death and morbidity statistics than in any other form. If the state makes these comparisons, local communities may wince under the sting of the lashing that comes to them. But there should be no complaint in the revelations: rather obligation for demonstration of the manner in which the unfavorable showing can be converted into a favorable one.—Cincinnati Enquirer.

The Town Planning Conference for Southwesern Ontario will be held at the Royal Connaught Hotel, Hamilton, Thursday, November 27th. and Friday, November 28th. This change in time was necessary due to the Victory Loan.

THE UTILIZATION OF SEWAGE SLUDGE

(Continued from page 422)

by mechanical action alone was not a success, and of all the various proportions of humus and ripe sludge mixtures made with the view of encouraging separation, the best result was obtained where the smallest quantity of the former was mixed with the largest proportion of the latter. This is understandable when one remembers that the "humus" contains 5% to 6% of nitrogen and the oxidized sewage effluent conveying it has in its composition a sufficient quantity of nitrates to arrest putrefactive tendencies. How long this humus emulsion will remain a jelly it is difficult to say, but there are samples on the works which still retain that jelly-like character after exposure to the atmosphere for six years.

The third is not the least important function of this lagoon. Water rises to the surface when fermentation is exhausted and frequently when it is quiescent, when it may be decanted direct to the filter-bed. When one remembers that by reducing a 90% to an 80% sludge, one gets rid of one-half its water-content, the importance of decanting as much liquid as possible is evident. It has also been proved that additional advantage is gained by providing deep lagoons, thus supporting A. J. Martin's theory that the deeper the tank, the denser the sludge obtained; at the same time the benefits in this respect must be measured by the degree of emulsification obtaining.

Drying Beds

The rotted sludge or residuum of the fermentation process is pumped direct to the drying-beds which are in the immediate vicinity. They consist of plots of engine ashes 150 ft. square and have a total area of 54 acres. All the plots are under-drained with 4-in. agricultural tile-pipes in herring-bone fashion (see Fig. 4) toward a main leader which conveys the drainage to a well, whence it is pumped with water decanted from the lagoons to a percolation filter made for the purpose.

Each drying-bed is formed by earthen banks about 2 ft. high. The area is provided with a system of permanent 2-ft. gauge tramways—laid to suit loco haulage, both steam and electric battery locos (see Fig. 7)—and provided with conveniently placed turnouts and crossings to allow temporary rails to be laid through the beds for the collection of dried sludge.

The time required for drying varies with the weather, but in dry weather it quickly cracks and admits air. Fig. 5 shows the appearance of the sludge three days, and Fig. 6 thirteen days, after it has been deposited. When it has become sufficiently dry to be lifted in lumps (see Fig. 8) it should be conveyed to the tip, as it is troublesome to the workmen when it gets into the dry-as-dust state; indeed, eye protectors have had to be provided in such cases. The embankments which are being formed of the dry sludge are about 15 ft. in height. When the lumps are tipped over the embankments, the drying is completed, and the estimations for calorific value dried at 212°F. give an average of 4,500 B.T.U., or something similar to the calorific value of ordinary house and shop refuse as burnt on a destructor.

Process Complete in Itself

It should be clearly understood that this process of sludge treatment is put forward as a complete process in itself, just as the Imhoff tank process was put forward by the German engineer, but without in this case any suggestion that the effluent from the sedimentation tank could be discharged into a stream. It effectually converts an exceedingly offensive colloidal mass of sewage into a dry substance, which might be kept in one's office for years without giving off more odor than would garden soil in similar circumstances. This conversion is accomplished without nuisance at any stage, and judging by pre-war costs the expense is similar to that incurred by London and Manchester. In a report which the author submitted to the Drainage Board in June, 1914, comparative costs were given as follows:—

	Pence per ton.
London	5.6
Birmingham	5.7
Manchester	6.9

The figures for cost given by the Royal Commission on Sewage Disposal are as follows:—

	Pence per ton (90% water).
Sea disposal	4.1 to 6.9
Trenching in soil	4.0 to 7.0
Pressing (for large towns)	7.7 to 12.6
Pressing and burning	18.0

Comparing sludge digestion at Birmingham with these figures, and assuming a wet sludge containing 90% water, it is approximately 5 pence per ton.

Cost figures are bound to vary, and in comparing sludge costs care should be taken to see that the percentage of water in the sludges coincides. Another statement showed the cost to be 6.3 pence per ton of sludge (86.6% water) made up as follows:—

Statement of Cost

1. Cost of tankage, digestion and pumping to drying beds:—

	£	s.	d.
Wages	1,622	10	0
Coal	710	5	0
Stores, etc.	90	9	0
Repairs, etc.	22	10	0
Water charges	75	5	0
	£2,520	19	0

The volume of sludge dealt with was 260,000 cu. yds. Approximate cost per cu. yd. of wet sludge, 2.25 pence.

2. Cost of drying sludge, lifting and carrying to tip:—

28,816 cu. yd. of dry sludge	£990 17 7
Cost of cu. yd. of dry sludge	8.3 pence
Cost of cu. yd. of wet sludge	2.5 pence

By adding (1) and (2), wet sludge 86.6% water = 4.7 pence per cu. yd., or 6.3 pence per ton.

That the scheme as illustrated at Birmingham is as perfect as it might be made, the writer does not claim. It has been an experiment, and has been extended from time to time always as an experiment. The great tanks and lagoons, with a total capacity of 28,000,000 gals., have been built in a temporary manner out of revenue as necessity has arisen, and the design or lay-out—apart from the biological side—if design it may be called, is obviously an improvization to meet current requirements and to obtain knowledge, rather than a consistent ideal based on some well-tested prototype. Indeed our calculations were so far out of truth originally that at one time we hoped that by an intensive fermentation at Saltley, the 20 brick-built tanks, which have a capacity of only 7,000,000 gals., would suffice for treatment of all the sludge arriving there.

Success Depends Upon Nitrogen

The adoption of the scheme which has been described was due to the impossibility of septicizing sewage and sludge together without nuisance. It has accomplished what it essayed to do, thanks chiefly to the consistent work of our chemist and superintendent of works, but its final success is dependent upon the profitable utilization of the nitrogen, which up till now has been lost sight of in the predominating desire to get rid of sludge with a minimum of nuisance.

With the object of recovering from the dry sludge nitrogen and other products of distillation, a boat-load of it has been sent to the Saltley Gas Works each week for some time. Absolutely trustworthy results will not be available until more producers are installed there, but the gas works engineer, Mr. Chaney, says that he is willing to give 3s. 6d. per ton for it delivered in boat at the Saltley Gas Works.

The fact that they are possessed of a plant capable of treating sludge for a moderate sum does not satisfy the Drainage Board that they have done all that they might to

utilize the nitrogen and grease found in it to the best advantage. Some boards might say that they have done all that is required of them by controlling effectually an enormous potential nuisance, such as is represented by arresting from 300,000 to 400,000 tons of sludge and converting it into a non-smelling dry substance (which under no circumstances can be reconverted into malodorous sludge) without establishing a huge municipal trading concern for the recovery of waste products, but the Drainage Board realize the possibility of doing more than they have done, and further that it is their duty to do more if that is possible, and with that in view they entered into a contract with the Anglo-Continental Fertilizers Syndicate, Ltd., just before the war began, by which that company agreed to treat about one-fifth of the Birmingham slude with the view of recovering from it both fats and fertilizers, but chiefly fertilizers. The outbreak of war upset the project for the time being, the Treasury absolutely forbidding the expenditure of money on work of this kind, with the immediate result of encouraging the gas works experiments, which have turned out as well, and now that the war is over the company's plans are to be put into the hands of builders whose initial work is essential before the company can begin to fulfil their agreement.

Fertilizer Company's Scheme

The scheme put forward by the company is one which the author hopes to deal with in a subsequent communication, but briefly it is as follows: The sludge is warmed to a temperature of about 90°F., when a small amount of yeast (from 0.5% to 1%) is added, and the mixture allowed to remain in suitable tanks for a period of 24 hours, provision being made to keep the mixture at the optimum temperature of 90°F. As the result certain important changes take place in the character of the sludge, the particles coagulating into a compact mass which separates from the water and rises to the surface, being buoyed up by the gases evolved from the ferment. The water is run off through perforated pipes, which, whilst allowing the liquid to pass, holds back the thick sludge, and enables the separation of the water from the sludge to be effected easily and quickly, and with a minimum of labor.

Some changes other than physical are brought about by the process, and the colloids are affected to some extent, with the result that the sludge is improved for subsequent treatment.

Fermentation reduces the sludge from, say 90% water content—which is the average of ordinary sludges—to 80%, equal to the reduction of one-half the water content, thus reducing the cost of treatment. The operation being a static one the cost of working is small.

The heat used for warming the sludge is obtained from the drying process, and may be either furnace gases, or hot air and vapor from the dryers, which would be otherwise wasted.

Product Reduced to Powder

The further treatment of the sludge depends to some extent on local conditions. Moisture may be got rid of by treatment in dryers heated by means of hot air, by direct heat, or in steam-jacketed drying-pans. It can also be reduced to about 50% by an intermediate process of pressing in ordinary sludge presses, and the cake, after being broken into small pieces, finally dried to a moisture content of from 10% to 15%.

The product is reduced to a fine powder for easy application to the land; it is then in a suitable condition for further treatment if grease is present in sufficient quantity to justify its recovery.

This process is too complicated to be disposed of in a few sentences, and the writer proposes to give a detailed account of it when the works are erected and in full operation.

In the end of 1918 a committee appointed by the Institution of Municipal and County Engineers impressed upon the government the need for investigating the whole question of recovering from sewage sludge products which are worth salving. One of the government departments (the National Salvage Council) had already made preliminary inquiries at the Bradford and Huddersfield sewage works, which convinced them that grease was being recovered profitably at both of those works, and the reply of that department was both prompt and sympathetic; later, the Board of Agriculture and the Local Government Board took cognizance of the institution's demands, and in consequence a committee was formed consisting of one representative of each of the following—viz., the Local Government Board, the Board of Agriculture, the National Salvage Council, the Institution of Municipal and County Engineers, and two experts on the salvage of grease from sewage sludge—the one an engineer and the other a chemist.

This committee, formed under the ægis of the government, has just issued their report, from which the writer makes the following extracts, with the cognizance and approval of the Assistant Director of the National Salvage Council, who acted as chairman of the committee:—

"We recommend that inquiry should be instituted in other towns* as to the grease content of local sludges, as we are of opinion that where a sludge after acidification contains 15% of grease calculated on a perfect dry basis, it is profitable to recover the grease, provided the selling price is not less than £15 per ton and 100 tons of wet sludge are available for treatment daily. In these figures no note is taken of the value of the dried degreased sludge; but this is saleable, and provided the nitrogen content is 2% or more, has a market value of 10s. to 30s. per ton.

"We are satisfied that there is a shortage of organic fertilizers in the country, and that it is likely to continue.

Nitrogen Lost by Delay

"It may be taken that the amount of wet sludge produced annually in England and Wales is roughly about 250 tons per thousand of the population drained. Assuming the population drained to treatment works to be 24,000,000, the average quantity of wet sludge produced annually is about 6,000,000 tons, equal to 600,000 tons dry matter (based on 90% moisture in wet sludge), of which quantity we estimate from the data before us that not more than 12½% is utilized for fertilizing purposes.

"We are of opinion that although the sludge, as at present disposed of by local authorities after air-drying or pressing, does not contain sufficient nitrogen to enable it to compete with artificial fertilizers in manurial value, there is sufficient nitrogen in the fresh sludge, as it is removed from the tanks, to give it a definite fertilizing value. We are further of opinion that considerable quantities of nitrogen are lost by delay in disposal, in some instances as much as 50% or more of the original quantity in the sludge, and that the nitrogen so lost is the most valuable from the point of view of the possible fertilizing value of sewage sludge.

"We consider that before any attempt is made to impress upon local authorities the advisability of utilizing sewage sludge as a fertilizer, efforts should be made to increase the manurial value of sludge by some method of treatment designed to fix more of the original nitrogen in the sludge. If this could be done, it would probably add a value of 10s. per ton for each additional per cent. of nitrogen retained in the sludge for use as a fertilizer. In this connection it has to be borne in mind that at the present time many local authorities are not only unable to sell the sludge, but in some instances are called upon to pay for its removal from the works even after it has been pressed into cake.

Activated Sludge More Valuable

"We recommend that controlled experiments be carried out on a suitable scale at selected disposal works in order to ascertain the best method of dealing with sludge so as to retain as much as possible of the original nitrogen and produce a fertilizer or fertilizer base.

"We have not specifically inquired into the results to be obtained from sewage treated by the activated process, but as a result of visits made by the committee to the Manchester

*Reference had been made to towns engaged in the woolen industries.

and Sheffield Sewage Disposal Works, where the activation by aëration and activation by agitation processes respectively are under investigation, it would appear that the residual sludge from such processes contains a higher percentage of nitrogen, and consequently as a fertilizer would be of greater value than sludge produced in the ordinary way. Experiments have been commenced to ascertain its fertilizing value, but further investigation is necessary to find out the best method of dewatering and drying.

"We are strongly of opinion that the time has arrived when a government committee should be appointed to follow the recent developments in the treatment of sewage and the recovery and utilization of by-products, with a view to collecting information for the guidance of local authorities and for the benefit of agriculturists."

This document from which the writer has taken extracts shows that the committee were under no illusion about the difficulties which must be overcome if substantial progress is to be made. Underlying the report there is a conviction that it is a matter of great importance that both fertilizers and fat should be recovered, that manure for which arable and pasture lands are yearning should not be thrown away. There is no suggestion that local authorities should spend a shilling to recover elevenpence, but it is implied that some local authorities have unwittingly allowed valuable substances to go to waste by failing to erect suitable plant for their recovery.

The need for creating this attitude of mind has been reinforced by the war. It has been proved that the efficient cultivation of the soil, which is impossible without manure, is quite as essential for the Defence of the Realm as the building of ships, and so, too, it may prove that the conservation of nitrogenous matter which now goes to waste is a national necessity.

COST OF CONSTRUCTING SEWERS AND WATER MAINS IN MONTREAL SOUTH, QUE.

DURING 1918, about 22,230 ft. of 6-in., 8-in. and 10-in. water main, and 25,300 ft. of 24-in., 12-in. and 9-in. sewer were constructed for the town of Montreal South, Que. The work was done by contract, and the following figures are the actual cost to the contractor. The contractor, by the way, made no profit.

The sewer work covered the construction of mains in 17 streets. The material in which the trenching was done consisted of hard pan at the surface, a layer of shale, a bed of trap rock 3 to 5 ft. thick at 5 to 8 ft. from the surface, and shale below the trap rock. The rock excavation was paid for at the rate of $4 per cubic yard over the other material. The rates of pay for labor were as follows:—

	Per hour, cents.
Common labor	35
Pipe layers	37½
Drillers	40
Blacksmith	40
Foreman	45
Single horse and driver	40
Double team	70

The units costs on four jobs were as follows:—

Materials:—	Job No. 1. 24-in. sewer, per lin. ft. of sewer.	Job. No. 2. 12-in. sewer, per lin. ft. of sewer.	Job No. 3. 12-in. sewer, per lin. ft. of sewer.	Job No. 4. 9-in. sewer, per lin. ft. of sewer.
Pipe	$1.800	$0.590*	$0.580*	$0.370*
Cement and oakum for joints	.160	.052	.052	.040
Manholes†	.270	.290	.246	.218
Coal and oil	.015	.012	.012	.009
Total material	$2.245	$0.944	$0.890	$0.627
Labor:—				
Cartage	$0.065	$0.050	$0.050	$0.027
Excavation and pipe laying	1.755	1.940	1.850	1.590
Rock extra	1.947	2.082	1.265	1.006
Back filling	.717	.624	.605	.515
Total labor	$4.484	$4.696	$3.770	$3.138
Grand total, material and labor	$6.729	$5.640	$4.660	$3.765

*Pipe and branches. †Brick with concrete bottom and cast-iron cover, cost $70 each.

Job No. 1 consisted of 1,780 ft. of 24-in. vitrified pipe sanitary sewer with 7 manholes. The average cut was 9½ ft. in hard pan, shale and trap rock. The total excavation was 2,350 cu. yds. with 867 cu. yds. of rock extra.

Job No. 2 consisted of 2,970 ft. of sanitary sewer, 107 6-in. branches, and 12 manholes. The average depth was 10 ft. in hard pan, shale and trap rock, with the latter close to the surface in places and varying 3 to 5 ft. in thickness between shoals. The total excavation was 3,260 cu. yds. with 1,550 cu. yds. of rock extra.

Job No. 3 consisted of 11,650 ft. of 12-in. sanitary sewer laid in five streets, 296 6-in. branches, and 41 manholes. The average cut was 8½ ft. in hard pan, shale and trap rock.

Job No. 4 covers 8 to 10 ft. of 9-in. sanitary sewer on nine streets with 284 6-in. Y-branches, and 27 manholes. The average cut was 8 ft. in hard pan, shale and rock.

Owing to the direction of veins in the rock, practically the whole of the work was done by hand, except the heavy fill on backfilling, which was done by steam tractor shovel.

The water main construction involved the laying of 3,560 ft. 10-in., 7,070 ft. of 8-in., and 11,600 ft. of 6-in. Class C cast-iron pipe. All the materials except the valves were imported from the United States. Cast-iron pipe and fittings cost $46.00 per ton (2,000 lb.) on car Philadelphia. Freight and duty brought the cost to $77.00 per ton on car 2 miles from line of work. The rates of pay were as follows:—

	Per hour, cents.
Common labor	30
Pipe layers	35
Foreman	40
Single horse and driver	40
Double team	70

The following figures represent materials and laying pipe and not excavation, as the work was done under separate contract during the laying of sewers. The sewer contract providing for the backfilling over the sewer pipe to the depth of 1 ft. to allow the water main to be laid, the sewer contractor completing the backfilling.

Materials:—	10-in. main, per lin. ft. of main.	8-in. main, per lin. ft. of main.	6-in. main, per lin. ft. of main.
Pipe	$2.747	$2.040	$1.387
Gate valves and boxes[1]	.109	.111	.060
Hydrants[1]	.109	.119	.128
Leadite[2] and coal oil for heater	.080	.067	.051
Total materials	$3.045	$2.337	$1.626
Labor:—			
Cartage from cars to line of work[3]	$0.035	$0.025	$0.017
Grading trench, pipe laying, packing pipe in trench, testing	.437	.378	.279
Total labor	$0.472	$0.403	$0.296
Grand total labor and material	$3.517	$2.740	$1.922

[1]6 10-in. double gate valves and boxes at $65 each, and 6 6-in. balance valve hydrants (6 ft. fill) at $65 each, with 10-in. main; 19 8-in. double gate valves and boxes at $41.50 each, and 13 6-in. balance valve hydrants at $65, with 8-in. main; 22 6-in. double gate valves and boxes at $31.50 each, and 22 6-in. balance valve hydrants at $65, with 6-in. mains.
[2]Leadite at 20 cents per lb.
[3]Cartage at $1 per ton.

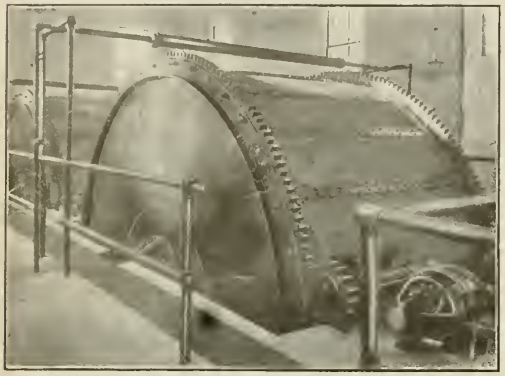
The above information was written by Ernest Drinkwater, consulting engineer, Montreal, for "Engineering and Contracting," Chicago, to whom *The Canadian Engineer* is indebted for same.

ROTARY WATER SCREENS

By L. N. Thompson
Department Engineer, St. Paul, Minn.

MOTOR-driven rotary screens are now being used very successfully by the city water department, St. Paul, Minn., for removing vegetation and solid particles from the drinking water. Prior to November, 1917, when the present system was put into operation, stationary screens were used which were cleaned with difficulty and required constant care, and were not very satisfactory. The rotary screens require practically no attention and have operated continuously since their installation.

The screens, as will be seen by the accompanying illustration, are cylindrical in shape, approximately 7 ft. long



Rotary Water Screens at St. Paul

and 14 ft. in diameter, with framework of structural steel, and have the appearance of large drums. One end is sealed tight by steel plates, the other end being left open for the entrance of water into the drum. The sides of the drum are covered with 24 sections 80-mesh Monel metal screens, which are also reinforced by ¾-in. mesh No. 8 copper wire.

The entire drum rotates about a hollow cast-iron shaft, or axle, 8 ins. inside diameter. By using two sets of roller bearings, very little power is required to operate them. A concrete wall, which is built at the open end of the drum, with an opening approximately the same radius as the drum, prevents the escape of water around the screens. Rubber belting is used between the concrete and metal frame to seal the joint.

Operation of the Screens

The unscreened water enters the open end of the drum and passes through the screens, leaving the dirt on the inside face. On the inside of the drum, near the top, extending the entire width, is a 4 by 6 ft. iron wash-water trough. Directly above the trough, on the outside of the screen, is a 4-in. pipe, the under side of which has a row of small holes, from which high-pressure streams wash through the screens and into the wash-water trough below. As the screens revolve past the trough, they are thus continually cleaned. The wash water is carried away through the hollow shaft, a very small amount of water being required to clean the screen thoroughly each revolution.

Drums Driven Independently

Either drum is driven independently of the other by a 7½-h.p. electric motor. A driving gear is connected at either end of the drum and any tortion is taken up by a differential. A speed regulator and two changes of speed in the gears give any desired rate of revolution and cleaning.

Two screens have been installed and provision made for a third. During the past year approximately 17,000,000 gallons passed the screens daily, which is far from their maximum capacity.

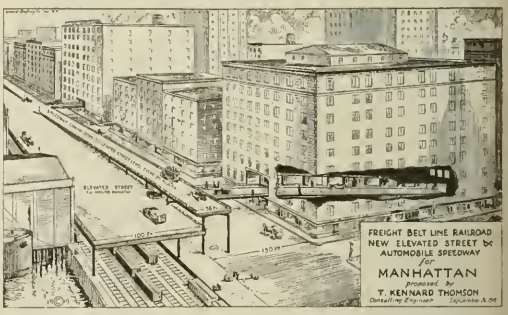
The screen chamber was built so that either or both screens can be shut off from service, and water passed around them without being screened. The screens were built by the St. Paul Foundry Co., and were designed under the direction of G. O. House, general superintendent, and W. N. Jones, engineer. The screen chamber was designed and constructed by J. W. Kelsey and L. N. Thompson, department engineers. All work was done by force account.—From "Fire and Water Engineering."

CANADIAN ENGINEER PROPOSES BIG RAILWAY SCHEME FOR NEW YORK CITY

DR. T. KENNARD THOMSON, a well-known engineering graduate of the University of Toronto, who has been in private engineering practice in New York City for many years, has designed a proposed belt line railroad to encircle Manhattan Island. The railroad is intended for freight service only. Above it, as shown in the accompanying sketch, is to be an elevated street 100 ft. wide, with a separate speedway 36 ft. wide. The speedway comes down to the level of the elevated street at every 20 blocks. Spaced only a few blocks apart, there are to be a number of inclined concourses from the elevated street to the old or lower street level. The elevated street and speedway, like the railroad, are to encircle the entire island.

Dr. Thomson declares that capitalists who are associated with him in the scheme are willing to build the railroad, streets and concourses entirely at their own expense, and donate the streets and concourses to the city without remuneration, provided that they are given a free franchise for the railroad.

The estimated cost of the whole scheme is about two hundred million dollars, but Dr. Thomson states that there are two hundred business men in New York who will finance it if the franchise is granted. When the scheme was sub-



Proposed Railway and Elevated Street, New York

mitted last month to the city's Board of Estimate and Apportionment, it was referred to the Committee on Franchises. Whether the franchise will be granted or not is a matter of considerable doubt; nevertheless the many Canadian engineers who know Dr. Thomson will, no doubt, be much interested in his ingenious scheme.

The American Association of Engineers received 902 applications for membership between October 1st and October 23rd, and the qualifications committee approved the admission of about 700 members.

The annual meeting of the American Road Builders' Association will be held November 7th at the Automobile Club of America, New York City. There will be two sessions for the purpose of receiving seven committee reports and annual reports of officers, electing new officers, etc.

CHICAGO DRAINAGE CANAL DIVERSION

AGAIN comes the plea, often repeated, for permission to increase the diversion of water for the Chicago Drainage Canal. This time Francis C. Shenehon, Dean of the College of Engineering, University of Minnesota, who was at one time District Engineer of the U.S. Great Lakes Survey, is its special advocate. He proposes that the effects of the diversion be compensated for by remedial works on the Great Lakes, these works to be financed by the Chicago Drainage Canal Commission.

The history of the canal is too well known to warrant repetition. It suffices to say that to-day the commissioners in charge of the drainage district, in defiance of all governmental authority, are diverting approximately 10,000 cubic feet per second, while the permit issued by the U.S. Secretary of War, in whom is vested jurisdiction over, and discretionary powers appertaining to, the navigable waters of the United States, gives them the right to divert not more than 4,167 cubic feet per second.

Canada has protested many times against this extraordinary state of affairs, but to no avail. As a matter of fact, the Canadian authorities were not even consulted when the original permit was granted. Many are the arguments against increased diversion and in favor of limiting the canal to the original permit of 4,167 cubic feet per second. Despite Canadian protests, the United States government has taken no adequate steps to enforce its orders and to prevent this wanton breach of constituted authority.

Mr. Shenehon now presents this scheme of remedial works which, if accepted, would allow the drainage commissioners to perpetuate their illegal diversion, and which would afford an easy method for the United States government to step out of its difficult position of being unable, even with the authority and prestige of its Supreme Court, to enforce its rightful prerogatives.

But this proposition is not acceptable to Canada; although remedial works on the lakes may partially compensate for the injuries to navigation, they cannot compensate for the power that will be lost to both countries as a result of the diversion. It is generally conceded by those who have been in intimate touch with the original scheme, that the development and sale of the power now obtained on the Drainage Canal under a 40-ft. head, is the great incentive to the diversion of additional water. The sale of this power is in the hands of the commissioners, and it finds a ready market in the drainage district.

This water, if carried along in its proper course through the Niagara and St. Lawrence rivers, could be used at the several points of development under a total head of fully 500 ft., which means approximately 500,000 h.p. Canada's share of this 500,000 h.p. will be permanently lost if the Chicago diversion is legalized by the acceptance of "compensation" for damages to navigation.

BRITISH OPTICAL FIRMS BUSY

ONE result of the war in England has been an enormous development of the optical manufacturing firms, states A. J. Ames, managing director of E. R. Watts & Son Canada Limited, who recently returned to this country after a four months' visit to his firm's English factory.

"As an instance of this development," says Mr. Ames, "I might mention that within a fortnight of my sailing for Canada, our London house had received orders for the following important geodetic instruments:—

"Twenty 12-in. micrometer transit theodolites reading to one second; fifteen 8-in. micrometer transit theodolites reading to two seconds; and one hundred and fifteen 6-in. micrometer transit theodolites reading to ten seconds.

"This does not take into consideration large orders for ordinary surveying and scientific instruments, nor does it reckon with the very large number of instruments connected with the various war departments in Britain, contracts for which are still being concluded.

"In pre-war time one seldom heard of an order for 12-in. micrometer theodolites for more than two at a time, and very often only one of these most important and precise instruments was ordered."

With labor conditions as they are in England, one wonders where all the business is coming from to keep the large optical firms so busy. However, everyone who has visited Great Britain since the war agrees that a wonderful change has taken place in the "old country," and that hereafter they are going to be more "up and doing" than ever. When British competition strikes its stride, Canadian and United States firms may have to hustle for their fair share of Canada's business.

NOVA SCOTIA POWER COMMISSION

UNDER the Power Commission Act passed at the last session of the Nova Scotia Legislature, a power commission for that province was recently appointed and is undertaking definite investigations with a view to an early development of certain water powers adjacent to the city of Halifax. The members of the commission are Hon. E. H. Armstrong, commissioner of Public Works and Mines (chairman), R. H. MacKay, of New Glasgow, and F. C. Whitman, of Annapolis. K. H. Smith, hydraulic engineer of the Dominion Water Power Branch, who for some time past has been in charge of hydrometric work and water power investigations in the maritime provinces and at the same time has acted as engineer to the Nova Scotia and New Brunswick authorities concerning water power matters, has been appointed chief engineer and acting secretary of the commission. It is expected that Mr. Smith will be able to continue in his present capacity with the Water Power Branch.

PERSONALS

J. C. Reilly, who was recently appointed acting general secretary of the Association of Canadian Building and Construction Industries, was born September 10th, 1881, in Toronto. He received his primary education at the Clinton St., Manning and Ryerson public schools, Toronto, and after two years in a law office and seven years with R. G. Dun & Co., he entered McGill University to study arts and theology. Mr. Reilly graduated from McGill in 1910, and became assistant at the St. James' Methodist Church, Montreal. Two years later he resigned in order to pursue further theological studies at the Harvard Divinity School, Boston. During the war he was overseas with the Y.M.C.A., returning in July this year. Mr. Reilly seems to have liked building construction as well as theology, as he was employed in various capacities by building contractors and architects during the summer vacations throughout his college courses. He was timekeeper, foreman, etc., on various large construction jobs in Montreal, including the McGill Engineering building. He has decided not to return to the ministry at present, and it is expected that his appointment as permanent secretary of the Association of Canadian Building and Construction Industries will be confirmed at the next annual conference of the association, which will be held the week of January 26th, 1920, in Ottawa.

J. A. Duchastel, city engineer of Outremont, Que., and past president of the Canadian Good Roads Association, has been nominated as one of the vice-presidents of the American Road Builders' Association.

A. W. Swan, assistant advertising manager, Canadian Ingersoll-Rand Co., Ltd., Sherbrooke, Que., has resigned in order to accept an appointment as assistant secretary of the Engineering Institute of Canada, with headquarters at Montreal.

Dr. Ernst Steiner, a member of the Swiss political and trade mission to the United States, is in Canada for the purpose of investigating our hydro-electric developments. Dr. Steiner has visited Niagara Falls twice and expects to go to Montreal and Winnipeg. He is a graduate of the polytechnic school at Zurich and is in private practice as a civil engineer. In an interview with *The Canadian Engineer*, Dr. Steiner stated that the Queenston-Chippawa development will be the greatest in the world at the time of its completion.

OBITUARY

J. E. Sirois, president of the Corporation of Quebec Land Surveyors, died recently at his home in St. Anne de la Pocatière, Que., aged 61.

The firm of C. H. & P. H. Mitchell, Toronto, has been consulted by the Nova Scotia Power Commission with a view to definite action at an early date.

Letter to the Editor

RULES FOR DRAFTING PRACTICE

Sir,—In reading the rules for drafting practice, by H. N. Savage, published in your issue of October 16th, I note that the dimensions of the drawings are somewhat similar to those originated by L. L. and P. N. Nunn for the Ontario Power Co. during the construction of the No. 2 pipe line. Each size is designated by a letter and the dimensions are multiples of letter size, as follows:—

Letter.	Out to Out.	Inside Border Line.
L	8½ by 11 ins.	8 by 10½ ins.
M	11 by 17 ins.	10¼ by 16¼ ins.
A	17 by 22 ins.	16 by 21 ins.
B	22 by 34 ins.	21 by 33 ins.
C	34 by 44 ins.	32½ by 42½ ins.
D	34 by (44+) ins.	32½ by [(44+)—¾] ins.

GERALD HAMILTON.

Niagara Falls, Ont., October 21st, 1919.

CORRECTION

In the report of the meeting held by the Toronto branch of the Engineering Institute of Canada for the adoption of a schedule of salaries, qualifications, etc., for engineers, the following paragraph appeared on page 397 of last week's issue of *The Canadian Engineer*:—

"After Mr. Clark had read the schedule in regard to railway work, Mr. Harkness inquired regarding the present rate of pay received by railway brakemen, and was informed by Mr. Clark that it amounts to between $300 and $330 per month."

Mr. Clark calls attention to the fact that the rate of pay mentioned by him is that received by railway freight conductors. Mr. Harkness had inquired regarding brakemen, but Mr. Clark's reply did not refer to brakemen's wages.

Pion & Grothe, contractors, have asked the city of Montreal to arbitrate their claims with regard to the construction of the Lasalle bridge, and have instructed F. C. Laberge to act for them. The city council recently decided to settle the claims in accordance with the Act passed by the provincial legislature.

Following is a partial list of Canadian patents recently issued through the agency of Ridout & Maybee, Toronto: Edward B. Killen, vehicle spring suspensions; Fred L. Rapson, lifting jacks and the like for use on motor, road and other vehicles; Woodington & Young, abrasive wheel; J. Stone & Co., Ltd., valves for fluid pressure systems adapted for operating bulkhead and like doors; Farm & Dairy Machinery Co., pneumatic valve actuating devices.

A public meeting of the North Atlantic Division of the National Highway Traffic Association will be held at the Automobile Club of America, 247 West 54th St., New York City, at 8 p.m., November 7th. The program includes the following: Progress report of committee on "Sign Posting for Detours and Through Routes in Municipalities," by Elmer Thompson (chairman), secretary, Automobile Club of America; "Present Status of Impact Tests on Roadway Surfaces," by A. T. Goldbeck, testing engineer, United States Bureau of Public Roads; "Motor Vehicle Traffic which Requires the Use of Cement-Concrete Foundations," by W. G. Thompson, state highway engineer of New Jersey; "Relation of the Motor Truck to the Railroad," by C. W. Reid, manager, Transportation Bureau, Federal Highway Council. Dinner will be served in the grill room of the club at 6.30 p.m. The public is invited to attend both the dinner and the meeting. Dinner reservations should be addressed to Elmer Thompson, 247 West 54th St., New York City.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Bedford Tp., Que.—The township council decided to carry out a programme of road improvement. Application will be made to the Provincial Road Department for $20,000 under the Good Roads Act, and the roads will be built as early as possible next year.

Golden, B.C.—Tenders are being called by the Provincial Public Works Department for the construction of a bridge over the Kicking Horse River at Golden.

Quebec, Que.—It is rumored that the provincial government will spend $10,000,000 on 650 miles of roads next year, provided that the federal subsidy of 40 per cent. of the cost of construction is forthcoming. Five trunk routes are planned: Montreal to the Laurentian Mountains, Montreal to Hull, Montreal to Sherbrooke, Levis to Rimouski, and Levis to Longueuil.

South Vancouver, B.C.—The sum of $60,000 has been spent on roads and sidewalks this year. This amount includes both work that has been done and contracts let, but not yet completed.

Toronto, Ont.—The completion of the Teraulay St extension, from College St. to St. Vincent St., will be taken up with the Board of Control by Mayor Church.

Vancouver, B.C.—The city council have received word from S. J. Crowe, M.P., that the federal Department of Public Works is prepared to expend the government grant for the repairs to Marine Drive bridge on terms previously arranged.

Victoria, B.C.—Plans for construction work on the Pacific Great Eastern Ry. include a steel cantilever bridge across the Cottonwood River.

Victoria, B.C.—The provincial Department of Public Works is arranging its programme of road improvements in the Fernie, Columbia Valley and Creston districts so that the main traversing trunk roads will be in such a state as to link conveniently with the Dominion government's Banff-Windermere highway on its completion.

Welland, Ont.—City engineer Chas. L. Coulson estimates the cost of extending Pine St. to Aqueduct St. at $2,500.

West Vancouver, B.C.—Permission has been given by the Dominion government for the appropriation of the $11,000 intended for the construction of a new bridge on Marine Drive, to be diverted to the repair of the old one.

WATER, SEWAGE AND REFUSE

Assiniboia, Man.—The municipal council will undertake the sinking of two 5-inch wells, and will supply same with the necessary pumps and platforms. Secretary-treasurer, Frank Ness, Kirkfield Park P.O., Man.

Brandon, Man.—City council is considering the installation of sewers in the eastern part of the city. City clerk, Harry Brown.

Burnaby, B.C.—A waterworks extension by-law will likely be submitted to the ratepayers in January. Clerk, Arthur G. Moore.

Grand Forks, B.C.—Work has started on the proposed irrigation system, and a complete topographical survey of the system is being made. District engineer, W. J. E. Biker, Court House, Grand Forks.

Guelph, Ont.—City council received a petition for the extension of the sewer on Lyon Ave. for a distance of 150 ft. City engineer, F. McArthur.

Hamilton, Ont.—City engineer E. R. Gray will prepare plans for the installation of a sewer on Simcoe St. West.

Hamilton, Ont.—The extension of the Burlington St. sewer, for the benefit of the Firestone Company's plant, which will be located here shortly, was discussed at a recent meeting of the works committee. City Engineer Gray estimates the cost at $34,000.

North Vancouver, B.C.—The city council have authorized the installation of a ¾-inch water service to H. Hobson's shingle mill at the foot of Bewick Ave.

Peterboro', Ont.—City engineer R. H. Parsons has been instructed by the city council to prepare plans for a sewage disposal plant to be installed in Otonabee district. Provision will be made in the plans for Imhoff tanks and a pumping station.

Peterboro', Ont.—The Board of Works has been asked by the Health Department to install a sewer to the site of the proposed Memorial School. The matter was referred to City Engineer Parsons.

Regina, Sask.—City council is considering a sewer and water extension to Block 15, C.P.R. Annex.

Toronto, Ont.—The Ontario Oakoal Co. have made an offer to the city council to take over the incinerator on Strachan Avenue, known as the cattle market site. The company propose to use the site for a plant for the manufacture of Oakoal.

Toronto, Ont.—Tenders addressed to T. L. Church (Mayor), chairman, Board of Control, City Hall, Toronto, will be received up to 12 o'clock noon on Tuesday, November 18th, 1919, for the supply and delivery of water meters. Specifications may be obtained at the Works Department, Room 12, City Hall.

Victoria, B.C.—The city council is considering extending the waterworks system to Gordon Head. City clerk, W. J Dowler.

Victoria, B.C.—City Engineer F. M. Preston is preparing a statement for Gordon Head, Saanich, showing the cost of irrigation.

Welland, Ont.—City engineer Chas L. Coulson estimates the cost of the proposed Crowland Ave. sewer at $15,650.

Winnipeg, Man.—Tenders addressed to R. D. Waugh, chairman of Commissioners, Greater Winnipeg Water District, 201 Tribune Building, will be received up to noon on Monday, November 10th, 1919, for the supply of remote electric control for two 36-inch gate valves. Specifications may be obtained at the office of the District.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, November 3rd, 1919, for laying the following water mains: In Jubilee Ave., from Lilac St. to Pembina Highway; in Brock St., from Academy Rd. to Lot 27, Block 9, Plan 1222, DGS. 51-2, St. Boniface. Specifications may be obtained at the office of the city engineer, 223 James Ave.

York Tp., Ont.—Deputations waited upon the township council relative to better water services on Beresford, Morningside and Watford Avenues and Durie St. Frank Barber, township engineer, 40 Jarvis St., Toronto, was instructed to make a survey and report upon same.

LIGHT, HEAT AND POWER

Galt, Ont.—The ratepayers will vote on a by-law to provide $30,000 for a central heating plant at the hospital. City clerk, Jos. McCartney.

Hampton, N.B.—The municipality will install an electric lighting system at a cost of $15,000.

Saskatoon, Sask.—Contract has been awarded for supply and erection of one 4,500 k.w. turbine and condenser for the power-house as follows: To the Canadian Westinghouse Co., Hamilton, $149,813. Rejected tenders from Dominion Bridge Co., Montreal, $159,310; Fraser and Chalmers, Montreal, $164,000. Separate tenders were also received for the turbine generator and switchgear as follows: Canadian General Electric Co., $92,609; Canadian Westinghouse Co., $114,643; Dominion Bridge Co., $126,500; Fraser and Chalmers, $132,000. Separate tenders for the condenser and equipment were as follows: Alberger Pump and Condenser Co., $24,135; Goldie and McCulloch, $29,965; C. H. Wheeler Manufacturing Co., $26,000; Canadian Westinghouse Co., $35,745; Dominion Bridge Co., $32,810; Fraser and Chalmers, $37,650.

Toronto, Ont.—A portion of the Glebe property between Harris' and Woodbine Ave. has been purchased by the Hydro-Electric Power Commission of Ontario for a power station in connection with the proposed eastern radials.

Unity, Sask.—Work will start immediately on the installation of an electric lighting system, estimated to cost $25,000. Secretary-treasurer, J. M. Jesson.

Winnipeg, Man.—Next year the city will spend $1,350,000 on its Hydro-electric system if a recommendation by the Fire and Light Committee is adopted by the city council.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, November 3rd, 1919, for the manufacture and delivery of steel towers required for a duplicate high-tension electric power transmission line between Point du Bois and Winnipeg. Plans and specifications may be obtained at the office of the City Light and Power Department, 54 King St.

York Tp., Ont.—The township council instructed their solicitor to prepare the necessary by-law to issue $2,000 worth of debentures for a hot water heating system in the school in Section No. 31.

RAILWAYS

Alvin, B.C.—Small and Bucklin, New Westminster, propose to construct a logging railway in Pitt Valley, near here.

Bancroft, Ont.—It is reported that the C.N.R. authorities have in mind the construction of a line from Bancroft and Combermere to connect with the C.N.R. line at Alice township, a distance of about 40 miles.

Edmonton, Alta.—The Dominion government has decided not to purchase the Edmonton, Dunvegan and British Columbia Ry., as was proposed. The C.P.R. has been looking over the line and may purchase it.

Quebec, Que.—A provincial charter has been granted to the Quebec and Chibogamau Ry. The company intends to build a line from Quebec City as far north as Lake Chibogamau. Joseph Cote, agent, of this city, is among the incorporators of the company.

New Westminster, B.C.—The Grand Forks–Lynch Creek branch of the Kettle Valley Railway is being reballasted and heavy rails will replace the light rails now in use. Considerable side-tracking will also be laid.

Oshawa, Ont.—On November 22nd the ratepayers will vote on the question of the construction and operation of the Toronto and Eastern Hydro radial, to operate between Bowmanville and Toronto.

Toronto, Ont.—City council endorsed the recommendation of the Board of Control to apply to the legislature for authority to issue debentures for $160,000 for the Bloor St. car line without the assent of the ratepayers.

Toronto, Ont.—City council decided to call for plans and ask Commissioner of Works R. C. Harris to advertise for tenders for the Mount Pleasant car line.

Toronto, Ont.—The construction of the Pape Ave. car line extension by July 15th next is called for by an order issued by the Ontario Railway and Municipal Board. Construction is to begin not later than April 15th.

Windsor, Ont.—Plans of the Ontario Hydro-Electric Power Commission to purchase the Sandwich, Windsor and Amherstburg Street Railway system were laid before the border municipalities on October 25th, by Sir Adam Beck, who has notified Mayor Winter that an order-in-council, giving power to the commission to take a vote of the people on the project, has been authorized by the Ontario government.

FACTORIES AND LARGE BUILDINGS

Alberni, B.C.—Parfitt Brothers, Victoria, have secured the contract for the erection of a new Indian school. Estimated cost of building, $70,000.

Brandon, Man.—A by-law will be submitted to the ratepayers at the next municipal elections to authorize the borrowing of $150,000 for erecting and furnishing new school buildings.

Bridgeburg, Ont.—An addition is being built to the Pratt and Lambert factory here which will practically double its capacity.

Burnaby, B.C.—The School Board is considering the erection of a school building north of Burnaby Lake.

Calgary, Alta.—The city council has been asked to provide a further sum of $102,140 for permanent improvements at the fair grounds, including a $45,000 addition to the cattle sheds.

Calgary, Alta.—Contract has been let to J. G. Edwards for the erection of a $30,000 garage at the corner of Second St. East and Ninth Ave. for Lougheed and Taylor. Work will be commenced shortly on this building, which will measure 120 ft. by 175 ft.

Chatham, Ont.—The Wilson Co., an American packing company, have purchased the Chatham Abattoir, and plan an extension to the building.

Edmonton, Alta. — A station costing approximately $1,000,000 and a big programme of expansion will be undertaken by the Canadian National Railways here. The station will likely be five stories high. It is also reported that the company will build shops in Edmonton similar to the Ogden shops at Calgary. The programme has been approved and only requires sanction of the Railway Board. It is expected work will start in the spring.

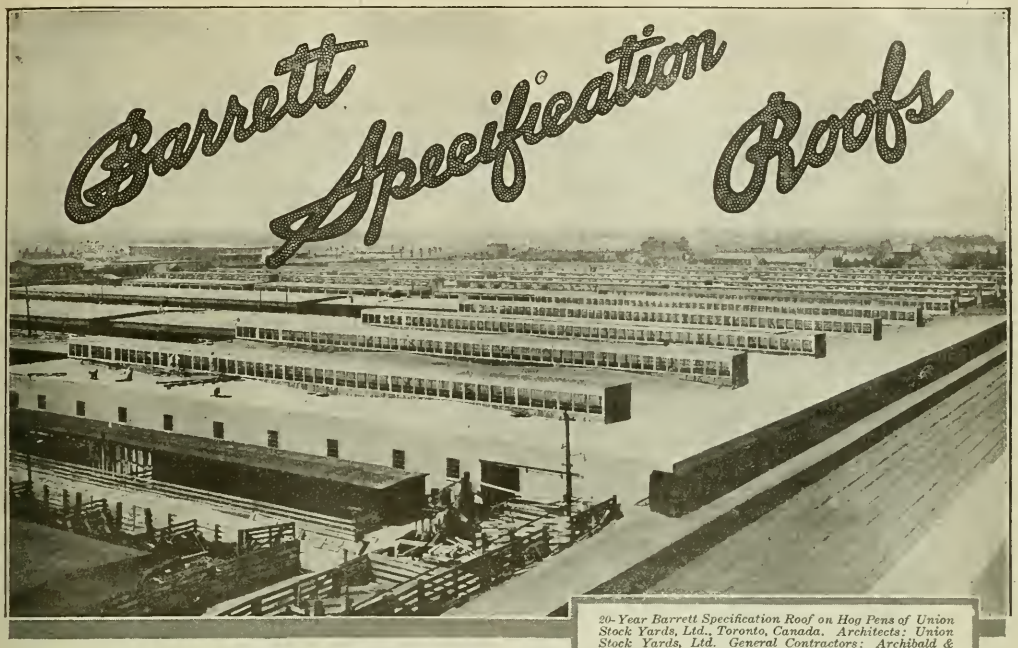
Edmonton, Alta.—It is probable that a new immigration hall, costing about $40,000, will be built here by the Dominion government next spring.

Edmonton, Alta.—A new building will be erected next year on 101st St. by the Edmonton "Journal." The new structure will have floor accommodation of 22,500 sq. ft.

Edmonton, Alta.—Contract awarded to Carter-Halls-Aldinger, of Winnipeg, for the erection of an eight-story warehouse in this city to cost approximately $150,000.

Edmonton, Alta.—Estimates on the cost of an eight-roomed addition to Norwood School, and also a new school on Spruce Ave., are being called for by the Public School Building Committee. Further information from Building Commissioner Story.

Edmonton, Alta.—The Public School Board decided to erect a model school in Garneau to serve as a temporary building until plans have been completed with the university authorities and the government for a permanent building on the university grounds. Tenders will be called for at once.



20-Year Barrett Specification Roof on Hog Pens of Union Stock Yards, Ltd., Toronto, Canada. Architects: Union Stock Yards, Ltd. General Contractors: Archibald & Holmes, Toronto, Can. Roofers: The Maitland Roofing & Supply Co., McDermid Bros. Successors, Toronto, Can.

100,000 Square Feet of Barrett Specification Roofs

The above photograph shows the mammoth new Hog Pens of the Union Stock Yards, Ltd., Toronto, in process of construction.

This is a roofing job of more than one hundred thousand square feet, covering one continuous building, extending back beyond the sixth monitor in the picture.

Naturally, in deciding what type of roof to adopt for this enormous plant, the question of cost had to be given careful consideration.

It is significant, therefore, that a Barrett Specification Roof should have been decided on.

It means that the Union Stock Yards architects fully realize what so many architects and builders have come to appreciate—that it *pays* to buy the *best* roof because, while the original cost may be a little higher, *the cost per year of service is lower than for any other type.*

This plant has a roof that will stand up year after year under the rigorous Canadian climate; one that takes the base rate of insurance and that is guaranteed for 20 years.

Guaranteed for 20 Years

So sure are we of the service Barrett Specification Roofs will give *under the most severe conditions* that we are prepared to *guarantee them for 20 years*, in all towns of 25,000 or over, and in smaller places where our Inspection Service is available, provided they are 50 squares or more in area. The guaranty costs you nothing. We merely require that our Specification dated May 1, 1916, shall be strictly followed and that the roofing contractor be approved by us. The guaranty is a Surety Bond issued by a well-known fidelity and guaranty company.

A copy of The Barrett 20-Year Specification, with roofing diagrams, sent free on request

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Hamilton, Ont.—The British-American Oil Co., Toronto, has decided to erect a $100,000 plant in this city. A permit for the erection of the building has been issued. President, C. S. Shorman.

Hamilton, Ont.—Tenders addressed to McPhie and Kelly, architects, Bank of Hamilton Building, will be received up to noon, October 31, 1919, for the erection of a Sunday school building on Summit Ave., Mountain. Plans and specifications may be seen at the offices of the architects.

Hamilton, Ont.—Bird and Son have secured a permit for the erection of an office building on Beach Rd., at a cost of $10,000.

Kitchener, Ont.—The Kitchener-Waterloo Collegiate Board decided to give competing architects until December 1st to submit plans for the proposed new Collegiate Institute building.

Kitchener, Ont.—The Industrial Committee of the Board of Trade has before it at present proposals from a United States spinning company about to locate a mill in Canada, and from another United States manufacturer of auto jacks and hardware specialties who will shortly establish a plant in Ontario.

Kitchener, Ont.—It has been announced here that certain local business concerns have invited W. N. McEachren, Son and Co., at present engaged in housing enterprises in other Ontario cities, to come to Kitchener to lead in the formation of a company, to be known as the Ontario Housing Co., with a view to solving the present housing stress in this city. It is understood that between 200 and 300 of the leading men of the city will make up the new company, and that between 15 and 25 houses will be erected immediately, and that this number will be augmented to between 200 and 300 houses in the spring.

Montreal, Que.—The Raymond Concrete Pile Co., Ltd., New Birks Building, Montreal, have been awarded the contract for the piling for the additions to the Holt, Renfrew and Co., Ltd., factory, McGill College Ave., Montreal, by H. C. Johnston Co., general contractors.

Montreal, Que.—The city council at their next meeting will be asked by the Administrative Commission to approve of the new by-law making it compulsory that all public buildings, schools, hospitals, hotels, large apartment houses and all buildings over sixty feet in height or more than three stories in height be built of fireproof material.

Montreal, Que.—Tenders addressed to the Catholic School Commissioners of Montreal will be accepted up to November 4th, inclusive, for the construction of the St. Thomas Aquinas School, Convent St., St. Henry. The said School Commissioners request the following: 1. Tenders for the general contract of said school. 2. Tenders for separate contracts on the following items: (a) Digging, excavations, masonry and concrete works, carpenters' work, plastering. (b) Electricity. (c) Roofing, tinning and ventilation. (d) Plumbing, heating. (e) Painting and glasswork. The plans and specifications may be examined at the office of Amos and David, architects, 76 Crescent St., Montreal.

New Toronto, Ont.—The Canadian Photo-Play Productions, Ltd., has purchased a site here for the erection of a studio to cost approximately $150,000. Steel, concrete, stone and brick construction. Excavation work has already been commenced.

New Westminster, B.C.—A new utility building being constructed by the Swift-Canadian Packing Co. at Sapperton is nearing completion. This work is costing between $6,000 and $7,000. A new cooler building has been completed and is now in operation, while an additional power plant is to be added.

Niagara Falls, Ont.—The Shredded Wheat Co., with plants on both the Canadian and American sides at Niagara Falls, will spend about $750,000 for plant enlargement.

Point Grey, B.C.—A permit has been issued for repairs to Shaughnessy Military Hospital to cost $20,000.

Port Coquitlam, B.C.—The Gregory Tire and Rubber Co. will erect a factory here.

Prince Albert, Sask.—The Prince Albert Hotel, which was partially destroyed by fire recently, will likely be rebuilt.

Prince Rupert, B.C.—Negotiations are under way between the city, the Grand Trunk Pacific and the American Canning Co. to build a plant here.

Province of New Brunswick.—Plans are ready for a new mill for the Nashwaak Pulp and Paper Co. in this province.

Quebec, Que.—Building permits have been issued to the Champlain Brewery Co. for the erection of a new structure at the corner of Church and Prince Edward Sts. at an approximate cost of $100,000, and to the Paquet Co. for the erection of a building at an estimated cost of $110,000.

Peterboro', Ont.—The Canadian Woollens, Ltd., have taken out three permits, aggregating $85,000, including a $40,000 factory building, a $10,000 office building and a $35,000 factory building at their Auburn plant. Architects, W. Blackwell and Son.

Port Colborne, Ont.—Tenders addressed to C. D. Howe and Co., superintending engineers, Port Colborne, Ont., will be received until noon of November 1st, 1919, for manufacture and erection of spouting and sheet metal work in connection with the reconstruction of the government elevator here.

Redcliff, Alta.—The Dominion Glass Co. is building a $100,000 addition to their plant here.

Regina, Sask.—Hancock, Sons and Co. propose to erect a monumental workshop and showroom.

Regina, Sask.—Excavation work has started for a $100,000 addition to the store of Seller and Sons.

Regina, Sask.—It is expected that $100,000 may be spent next year to extend the Fort Qu'Appelle Sanatorium.

Regina, Sask.—The Western Implement Co., of this city, has let contract to D. J. McKay for the erection of a warehouse on Osler St. North. Estimated cost, $15,000.

Regina, Sask.—The Saskatchewan Oakole Co., which is being incorporated here, proposes to erect a building at a cost of $35,000 or $40,000 for the manufacture of garbage into fuel briquettes.

Regina, Sask.—The American Corporation, New York City, organized by E. H. Turnbull, of London, Eng., who is associated with Gen. J. F. O'Ryan, of New York, has purchased 200 lots in this city, and plans are under way for an extensive house building scheme to be undertaken in the spring.

Renfrew, Ont.—Construction work on the Carnegie public library will be proceeded with shortly.

Renfrew, Ont.—The ratepayers passed a by-law to raise $25,000 for the erection of a new fire hall. Along with the fire hall there will be installed a central heating plant. Town clerk, J. A. Devenny.

Sandwich East, Ont.—The General Motors Corporation have purchased 600 acres here. The land, which is near the $6,000,000 plant the corporation is building on the Walker Rd., Walkerville, will be used as the site of a model town for employees. In the meantime temporary quarters will be erected by the corporation. More than $1,000,000 will be spent in building workmen's houses.

Saskatoon, Sask.—Two hundred thousand dollars is the sum stipulated in a resolution drawn up by City Commissioner C. J. Yorath, and endorsed by the G.W.V.A., asking for assistance from the government for the city in providing homes for returned soldiers.

Sherbrooke, Que.—The Canadian Connecticut Cotton Mills may erect a factory here.

Sherbrooke, Que.—The city council has selected a site for the erection of a Technical School. Mayor, Chas. D. White.

Sherbrooke, Que. — The provincial government will shortly pass an order-in-council providing for a loan of $500,000 to this city for housing problems.

The Best Books for Railroad Engineers

FIELD ENGINEERING, Complete.

Eighteenth Edition, Revised and Enlarged. Total Issue, 59,000.

A Handbook of the Theory and Practice of Railway Surveying, Location and Construction. By WILLIAM H. SEARLES, C.E., and HOWARD CHAPIN IVES, C.E.

This standard work presents the general subject of railway field work in a progressive and logical order, for the practising engineer. All the more important practical questions are discussed and non-essential matters are avoided. In this edition the American Railway Engineering Association Spiral is included, adding materially to the practical value of the book.

657 pages. 4 by 6¾. 148 figures, 4 folding plates. Flexible binding, $3.00 net.

RAILROAD STRUCTURES AND ESTIMATES

Second Edition, Fully Revised.

By J. W. ORROCK, Prin. Assist. Engineer, C.P.R.

In addition to its many other good qualities, this book makes a feature of quantities for track material, that to a very large extent is not dealt with in other books on the subject. Every contractor engaged in railway work should possess a copy.

vii. + 574 pages. 6 by 9. 272 figures. Flexible binding, $5.00 net.

RAILROAD CONSTRUCTION

Sixth Edition, Revised and Enlarged. Total Issue, 13,000.

By WALTER LORING WEBB, C.E., Mem.Am.Ry.Eng. Association.

The science of railroad construction has made a great advance in the last few years. The American Railway Engineering Association's decisions, in general the highest authority obtainable, are quoted where it has been found advisable to do so. Valuable advice is given regarding the handling of surveying parties, including emergency medical and surgical treatment.

Sorel, Que.—Tenders addressed to R. C. Desrochers, secretary, department of public works, Ottawa, will be received until 12 o'clock noon, Friday, November 7, 1919, for the reconstruction of corner in concrete and other repairs to wharf at Sorel. Plans may be seen and specification obtained at the department of public works, Ottawa, at the offices of the district engineers, Shaughnessy Building, Montreal, Que., Post Office Building, Quebec, Que., and at the post office, Sorel, Que.

Sydney, N.S.—President Mark Workman, of the Dominion Steel Corporation, has announced the immediate undertaking of new submarine coal mining operations, with headquarters at Bonar Point, on the north side of Sydney harbor. The work is being undertaken for the purpose of supplying the high grade of metallurgical coal required for the manufacture of the steel to be used in the new plate mill, and foreshadowed important shipbuilding developments. The plans which have been prepared for the new workings involve the expenditure of approximately $2,000,000, and provide for the most modern equipment available.

Three Rivers, Que.—The Raymond Concrete Pile Co., Ltd., New Birks Building, Montreal, have been awarded a contract for piling for two additional shipways for the Three Rivers Shipyards.

Toronto, Ont.—Tenders, addressed to T. L. Church (Mayor), chairman, Board of Control, will be received up to noon on Tuesday, November 4th, 1919, for supplying 6,000 feet of 2½-inch fire hose. All information may be obtained upon application at the office of the Fire Department, No. 152 Adelaide Street West, Toronto.

Toronto, Ont.—G. L. Ridout, 73 Grosvenor St., Toronto, desires to rent a steam shovel and trenching machine, and is in the market for the purchase of drain tile. He has a contract for excavation and construction of new football field for Upper Canada College.

Victoria, B.C.—Two large and powerful motor boats are to be constructed by the marine department. Tenders will be called for shortly and the contract will be awarded early next month.

Winnipeg, Man.—The Pan Extension Gold Mines Co., Ltd., is negotiating for machinery, hoists, air compressors and a complete plant for installation at their property.

Steam Turbine Driven Turbo-Blower Set

With Condensing Plant. For quick delivery from stock at very favorable price.

GOOD OPENING for ambitious young man, graduate in Mechanical Engineering, preferably under thirty years of age. Canada Forge Co., Welland. 362

WANTED.—Experienced Structural Steel Detailers and Checkers. Apply, stating experience and salary required. Manitoba Bridge and Iron Works, Ltd., Winnipeg, Man. 365

COST MAN, eight years' experience in Canada, principally on construction, maintenance and repair work, is open for position. Can take complete charge of office, payrolls, purchasing, etc. Address Box 19, *Canadian Engineer*, Toronto.

ENGINEER WANTED to take charge of a Buffalo office of a Canadian engineering and contracting firm doing contract work. Duties are partly engineering and partly selling. Good opportunity for live man. Address Box 13, *Canadian Engineer*, Toronto.

MANUFACTURER in Eastern Townships, having good facilities and considerable experience in the production of a wide variety of machinery lines, desires to undertake the manufacture (for the Canadian or export trade) of American or English machinery. Full particulars gladly upon request. Box 396, *Canadian Engineer*, Toronto.

COMMISSARY work for construction undertakings is my specialty. Before entering this line, I had eight years' experience as an accountant in the Canadian Bank of Commerce in Toronto and other Canadian cities. Am a Canadian, married, good references. During last year of war had entire charge of all feeding and living accommodations, timekeeping, etc., for large shipbuilding corporation in United States. Interview solicited. Address Box 398, *Canadian Engineer*, Toronto.

According to a circular received from Alfred D. Flinn, secretary of the U.S. Engineering Council, the following eleven states in the United States have laws on their statute books for licensing of engineers: Wyoming (Act passed in 1907), Louisiana (1908, amended 1914), California (1909), South Dakota (1913), Illinois (1915), Iowa (1919), Idaho (1915), Florida (1917), Oregan (1919), Colorado (1919) and Michigan (1919). As yet the U.S. Engineering Council has taken no stand on the desirability of licensing or registering of engineers, but the license committee is working on a draft of a typical bill.

Effect of Water Uplift on Overturning of Dams

Theory Advanced That Water Pressure Acting Upward Replaces Portion of Foundation Reaction and That Its Overturning Effect Is Annulled by Counter Moment Produced by "Remaining Foundation Reaction"—Effect of Uplift Upon Sliding

By ERWIN MAERKER

Formerly Structural Engineer, Toronto Power Co.

THE method usually followed by engineers engaged in the design of dams (and other structures resisting water pressure), is to add the upward water pressure under a dam to the reaction of the foundation against the base of the dam, causing an additional overturning moment. The writer cannot agree with this theory, and he regards uplift as a force replacing part of the foundation reaction instead of adding to the foundation reaction.

It is not within the scope of this article to determine the amount and distribution of the uplift; that is, whether pressure due to the full head should be allowed at the heel of the dam, or a fraction thereof, or whether the pressure should diminish uniformly to zero at the toe of the dam, or vary according to a parabolic law or otherwise; but the article treats with the effect of the uplift assumed to act on the base of the dam.

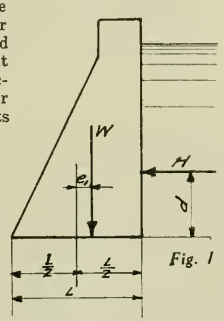

Fig. 1

Fig. 2

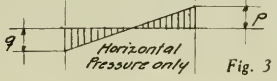

Fig. 3

Assume a block of masonry 20 ft. in height, with base dimensions of 1 by 15 ft., resting on its foundation. With a unit weight of masonry of 150 lbs. per cu. ft., the foundation reaction will be $20 \times 150 = 3{,}000$ lbs. per sq. ft.

For the sake of simplicity we will confine ourselves to vertical forces only, and omit horizontal water pressure, without in the least affecting the principle. Assume further a uniform upward water pressure of 1,000 lbs. per sq. ft., corresponding to a head of 16 ft., to act with equal intensity on the base of the block of masonry. Since the weight of the block of masonry produces a downward pressure of 3,000 lbs. per sq. ft. and the upward water pressure is only capable of exerting 1,000 lbs. per sq. ft., it is evident that the foundation reaction still in contact with the base of the block, must exert 2,000 lbs. per sq. ft. By increasing the uplift to 3,000 lbs. per sq. ft., the block will be entirely sustained by the interposed film of water between base of block and its foundation, and the block will be floating.

Fig 5 shows the uplift varying uniformly from 1,000 lbs. per sq. ft. at one extremity of the base to zero at the other extremity. The common error made is to regard the uplift as producing an overturning moment on the block, but the fact that the remaining foundation reaction is also producing an overturning moment counter to the moment of the uplift, is completely lost sight of. The two moments annul each other, and their total upward pressure is 3,000 lbs. per sq. ft., the upward water pressure substituting itself in place of the foundation reaction.

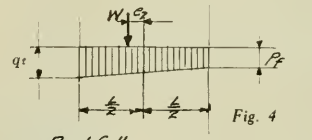

Fig. 4

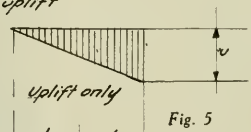

Fig. 5

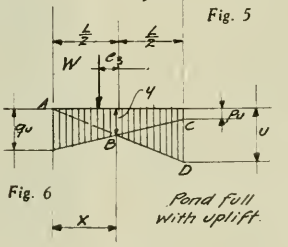

Fig. 6

How the uplift can be regarded as producing an overturning moment, and at the same time the counter-moment of the foundation reaction be wilfully neglected, is beyond the writer's comprehension. It is a case of mechanics, pure and simple.

Lamar Lyndon, in his first volume on "Hydro - Electric Power," speaking of this added overturning moment, writes:—

"How such a weird fancy could have ever obtained the importance of a standard engineering rule of design, is beyond the writer to understand, being contrary to every law of physics, mechanics and common sense."

In case the uplift exceeds the foundation reaction at the heel of the dam, there will be an excess pressure acting upward, and it is this excess pressure only which will have to be considered as producing an overturning moment. The following equations will make this clear:—

Let W = Weight of dam per foot of length.
H = Horizontal water pressure.
L = Length of base.
d = Distance of H above base of dam.
e_1, e_2, e_3 = Eccentricity.
p = Pressure at heel of dam.

q = Pressure at toe of dam.
u = Uplift at heel of dam.
W_u = Weight of dam per foot of length, diminished by excess uplift.

Subscripts e, f and u refer to "pond empty," "pond full" and "pond full with uplift," respectively.

Foundation Reaction, Pond Empty.—Pressure on foundation due to direct load plus or minus couple $W \times e_1$. See Fig. 2.

$$p_e = (W/L)(1+6e_1/L) \quad \ldots\ldots(1)$$
$$q_e = (W/L)(1-6e_1/L) \quad \ldots\ldots(2)$$

Foundation Reaction, Pond Full, No Uplift.—See Figs. 3 and 4. $Hd = pL^2/6 = qL^2/6$. Solving for p and q:—

$$p = q = 6Hd/L^2 \quad \ldots\ldots(3)$$
$$p_f = p_e - p \quad \ldots\ldots(4)$$
$$q_f = q_e + q \quad \ldots\ldots(5)$$

Also,
$$p_f = (W/L)(1-6e_2/L) \quad \ldots\ldots(6)$$
$$q_f = (W/L)(1+6e_2/L) \quad \ldots\ldots(7)$$

From this,
$$e_2 = (Hd/W) - e_1 \quad \ldots\ldots(8)$$

Foundation Reaction, Pond Full, With Uplift.—When $u \leqq p_f$, no change results due to uplift, as far as overturning moment is concerned, and equations 4 and 5 are to be used. For sliding, however, subtract $uL/2$ from W, since only that part of the dam which is in actual contact with the foundation produces friction.

When $u > p_f$ the procedure is as follows: The excess uplift BCD in Fig. 6 causes foundation reaction in Fig. 4, namely p_f and q_f, to change to p_u and q_u respectively in Fig. 6, so as to make the sum of all moments equal zero and the sum of all vertical forces equal zero.

Taking moments about A (see Fig. 6),
$$W(L/2-e_2) = uL^2/3 + (q_u x/2)(x/3).$$
But $W = uL/2 + q_u x/2$, and solving for x,
$$x = [6W(L/2-e_2) - 2uL^2]/(2W-uL) \quad \ldots\ldots(9)$$
And
$$q_u = (2W-uL)/x$$
$$= (2W-uL)^2/[6W(L/2-e_2) - 2uL^2] \quad \ldots\ldots(10)$$

From similar triangles:—
$$u/L = y/x, \text{ and } y = ux/L.$$
Also
$$(q_u - p_u)/L = (y-p_u)/(L-x).$$
And from these two equations,
$$p_u = u - q_u[(L-x)/x] \quad \ldots\ldots(11)$$
$$W - \Delta BCD = W_u = \tfrac{1}{2}(p_u+q_u)L \quad \ldots\ldots(12)$$
Since $q_u = (W_u/L)(1+6e_2/L)$,
and $p_u = (W_u/L)(1-6e_2/L)$,
$$e_2 = \tfrac{1}{6}L(q_u - p_u)/(q_u + p_u) \quad \ldots\ldots(13)$$
When $p_u = 0$, $e_2 = L/6$.

For sliding, subtract $\frac{1}{2}uL$ from W.

In conclusion it will be said that the uplift is usually assumed much larger than necessary. If a horizontal plane be cut through the base of the dam, the area of the voids in practice would not exceed 25% of the total area, except under extraordinary conditions, and since the water could only fill these voids, the unit uplift pressure exerted could only be 25% of the pressure assumed. The unit pressure of the dam against the foundation would then be $1 \div 0.75 = 133\%$ of the actual contact area, since only 75% of the base area would come in contact with the foundation.

PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSING OF TURBINE GATES*

By William P. Creager
Assistant Hydraulic Engineer, J. G. White Engineering Corporation, New York City

THE theory of water-hammer in penstocks is one of the most intricate problems confronting engineers. Mr. Gibson has made a considerable addition to the knowledge of the subject; but exact solutions for all conditions have not yet been reached.

He has developed rational equations for penstocks of constant diameter and negligible friction head. In cases where friction head is relatively large, and particularly where the penstock has a varying diameter, we are still very far from a practical solution.

At any instant during gate closure, the discharge through the gate is a function of the static head, plus water-hammer head, less friction head, all measured at the gate.

Mr. Gibson makes the assumption that the friction head at the gate is proportional to the square of the velocity adjacent to the gate. This assumption appears to the writer to be only approximate, since it is well known that, at any instant during surges, the velocity is materially different at different points on the penstock.

It is the writer's opinion that, during the period $2L/a$, subsequent to a single small instantaneous closure, the friction head at the gate is not constant, although the velocity adjacent to the gate during that period is constant. This constantly varying friction head makes it very difficult to include this feature in the equations for water-hammer, and, in all probability, Mr. Gibson's methods are as close as can be obtained. It would be of interest to know how much difference the incorporation of friction head makes in ordinary problems.

For a penstock with varying diameter, auxiliary waves are set up each time a water-hammer wave passes a point of change in diameter. For this condition, Mr. Gibson's equations would not apply. His methods would apply, but they would be exceedingly difficult, if not impossible, of practical application.

It is evident that the maximum rise of pressure is materially influenced by the characteristics of the gate-closure curve. It is well known that modern turbine governors do not provide a uniform rate of gate closure throughout the stroke. It is also possible that governors of different types have different closure characteristics. Consequently, complete data for the determination of maximum water-hammer for specific cases must include the gate-closure characteristics of the governor, which is to be a part of the machinery.

*Discussion (presented to the American Society of Civil Engineers) of Norman R. Gibson's paper (see September 4th and 11th issues of *The Canadian Engineer*).

TO CONSIDER PAY FOR ESTIMATES

TENTATIVE arrangements have been made for a conference to be attended by committees from the American Institute of Architects, the U.S. Engineering Council, and the Associated General Contractors of America, for the purpose of considering "payment for estimating." At present it is planned to hold the first meeting November 17th at Hotel La Salle, Chicago.

For the Associated General Contractors, a special committee has been appointed, consisting of the following: A. P. Greensfelder, of the Fruin-Colnon Contracting Co., St. Louis; James O. Heyworth, of the Chicago company of that name; and A. E. Wells, of the Wells Brothers Construction Co., Chicago. Mr. Greensfelder is the chairman of the A.G.C.'s Committee on Methods, which had general supervision of the discussions regarding "payment for estimating."

Engineering Council has named as its delegates, Ralph Modjeski, Samuel G. Neiler and Theodore L. Condron, while the Post-War Committee of the American Institute of Architects will be represented by George C. Nimmons, Richard E. Schmidt and Frederick W. Perkins, with Henry K. Holsman as alternate.

In a report recently made by F. A. Gaby, chief engineer of the Hydro-Electric Power Commission of Ontario, the estimated cost of the proposed hydro-radial from Toronto to Bowmanville, via Pickering, Whitby and Oshawa, is given as $8,360,794; the estimated annual revenue, $1,118,003; and the estimated annual operating expenses, including 5% interest on capital expenditure, $1,076,175. Of the $1,118,003 income, $873,140 is expected from passenger traffic and $244,863 from freight.

HOUSING AND TOWN PLANNING*

By Thomas Adams
Town Planning Adviser to the Dominion Cabinet

WE have a great opportunity in Canada to make our housing conditions right, because it is a new country. In older countries, like England, attention is being devoted to the solution of a housing problem that arises from bad conditions which we can prevent in this country. It is obviously a much easier operation to prevent bad conditions than it is to remedy them after they have become established.

Some idea of the enormous problem that they have to deal with in England may be gathered from the fact that they propose to build under government agency from 300,000 to 400,000 houses at a cost of from $2,500 to $4,000 each, involving a loss to the country—when they come to make up the difference between the cost of the houses and their value as an investment, likely to result from the fall in prices which will take place in a few years—of several hundred million dollars.

They are facing this loss at a time when they have not very much money to spare for anything which is not an absolute necessity. That is because the problem in England has been neglected too long. Here in Canada we are still in the formative stage as a country. Rapid as our growth has been, great as has been the development in the last 20 years, still our biggest housing problem is to prevent bad conditions of growth in the future rather than to correct the evils of the past.

We have a chance to prevent such a catastrophe as that of handing down to the future citizens of this country the evils that are characteristic of the slums of older European cities. We cannot delude ourselves with the idea that we have not begun to create the germs of slums in our big cities. Without a doubt the conditions already existing in our few big cities are comparable with some of the worst conditions in European cities. These existing evils must be attacked and some remedy found for them, but it is still true that with us the greater task and the greater responsibility is to prevent the further growth of these evils by preventive measures.

Workmen's Cottages at Gretna

In both Canada and the United States we have the beginnings of slums, and we have a similarity of conditions that enables us to compare them to our mutual advantage. One of the things of which housing experts and town planners are convinced is that the solution of the housing problem depends most largely on applying right methods of planning and developing the land, and on the extent to which these methods lessen the evils that arise from land speculation.

One of our chief tasks is the prevention of bad conditions in the new suburbs of our cities, without diminishing our efforts to remove the evils prevailing in the centres of the cities. All our cities are surrounded by scattered and somewhat disorderly developments, and one difference between a Canadian city and a city, say, in the Mother Country, is that whereas our new suburban developments are among the worst we have, the bad housing conditions in the English city have been mostly handed down from the past. With us, some of the worst conditions are those which we are creating to-day, in the form of unsanitary shacks in the suburbs of our cities. If you want to see the worst conditions in Ottawa, for instance, you must go not to "Lower Town," or to the centre of the city, but just over the city boundaries, in what is practically a "no man's land," between the city and the country, and where there is a lack of sufficient control and interest to secure proper conditions.

Government Housing Scheme at Well Hall, Woolwich

Garden City at Letchworth

One of the movements in England of great interest to housing reformers is the Garden City at Letchworth, near London. It proves the advantage of town planning as a basis for practical housing improvement. If there is any experience in my own life which I look back upon as having the most value to me as a town planner, it is the experience I had during the few years that I was connected with the building up of that garden city. We started *de novo*; we considered the problem right from the beginning and commenced the building of a new city unhampered by existing vested interests. That scheme was started for the purpose of establishing certain principles and to take advantage of a prevailing tendency of manufacturing industries to migrate from large centres of population to rural districts, a tendency which is very prevalent in this country also.

Industrial Decentralization

I have just been making some investigations in connection with housing conditions in Toronto, and one of the things we are inquiring into is the extent to which the movement of industrial plants from the city proper out into

*Address delivered October 18th, 1919, at the Ottawa Conference of the American City Planning Institute and the Town Planning Institute of Canada.

the suburbs has affected the housing situation. You would be surprised to know how many industries have moved out of the central districts of Toronto, within the last few years, into the suburbs, where they have created a new demand for houses and new questions of transportation.

These industries have been moved into districts where they can get cheap land and transportation facilities, but adequate consideration has not been given to the question of housing for the workers.

This problem of the decentralization of industry has been in existence for the last 20 or 30 years in Britain. Big industries have been moving out of London and other large centres to the country districts, and the originators of the Garden City movement said:—

"Let us take hold of this movement. Let us start a new city and offer attractions to these industries that are looking for new locations. Let us group these manufacturers together and build houses for their employees. Let us give them up-to-date transportation and other facilities. Let us conserve the whole of the unearned increment of the value of the land created by the inhabitants for their own benefit; and see if we can establish a city which will be a model in connection with both the housing question and the land question."

Well, they have been comparatively successful: 3,800 acres were purchased at about $200 an acre. The promoters planned the site of the city, they put in an electrical installation, gas works and a pure water supply. They prescribed that there should not be more than seven or eight houses to the acre. They put all the industries in one part of the estate, where the prevailing winds took the smoke away from the town. They improved the transportation system. The worker in Garden City lives within five minutes' walk of his place of employment; no costly transportation system takes him from a point ten miles out in the suburbs to a plant in the centre of the city, requiring him to spend two or three hours a day in going to and from his work.

Planning Increases Working Time

I venture to suggest, in connection with the discussions that took place at the recent National Industrial Conference, that this is one of the matters which has a distinct bearing upon the number of hours a day that an employee can reasonably give to his work. Every year we are increasing the aggregate distance between the factory and the home of the worker. A man may work eight or nine hours a day in a factory, but if he spends two or three hours a day hanging on to a strap, going to and from his work, he is going to continue pressing for the reduction of the time he gives to productive forms of labor, and is going to continue to be a less efficient instrument of production than if he lived near his place of employment. So this very question of the number of hours that the workman wastes each day in unnecessary travelling, as a result of unregulated distribution of industries and population, has a definite bearing upon the question of efficiency and output of labor.

We cannot repeat the Letchworth experiment all over the country, but if we had in Canada a place where manufacturers were already moving and where we could organize such an industrial development, it would be an excellent thing. It would have a great value in demonstrating the efficiency of scientific organization and of planning for the purposes of solving the housing problem, the land problem and the transportation problem, and of promoting industrial efficiency.

Unearned Increment Reserved

In the Letchworth scheme, the unearned increment in the value of the land is conserved for the benefit of the community. I have said that the land for the Letchworth garden city was purchased at $200 an acre. The value of that land has now increased to $1,000 and $2,000 an acre, and the whole of that increase in value is conserved for the benefit of the inhabitants of Letchworth. There can be no private property in land in Letchworth. You can acquire a lease for 99 years, with the right to renew at the end of that period, subject to revaluation, but you cannot acquire private property in land.

The land was purchased by a company, as a trust for the inhabitants, which laid down the conditions that the whole of the increase of value due to the conversion of the land from agricultural to building purposes, should be conserved for the benefit of the community. But it has to be pointed out that the people of Letchworth have been able to make their largest profits in the earlier years of development on account of the efficiency with which they are able to distribute gas, electricity, water and the other necessities of life, because of proper planning. The control of these things is often handed over, without thought, by franchise, to private concerns.

Agricultural Belt

An important and interesting feature of the Garden City scheme is the agricultural belt round the city. The city area comprises about 1,200 acres, laid out for a population of 30,000 people. In this area there are at present about 30 factories and 13,000 people. In 1903 there were about half a dozen farm houses and laborers' cottages on the site of the city. The other 2,600 acres of the original area, with an additional 700 acres recently acquired, are reserved as a permanent agricultural belt round the city. The charter under which the city is established provides that this belt must be reserved permanently for agricultural purposes or for such recreation purposes as golf. Thus the inhabitants have a large open area all round the city which can never be built upon, and the produce is brought close to the door of the consumer. If the city increases its population over 30,000, it must extend by leaping over the agricultural belt. Thus the industry of farming is linked up with manufacturing industries in one community, avoiding the usual separation of town and country into two distinct zones with the inhabitants of each pulling against one another. The city of the future should have its farm zone, with more harmonious relations established between the workers on the farm and in the factory. Letchworth proves the practicability of the combination, and in contrast the cities of this continent show the evils that arise from the excessive degree to which they promote the separation between agriculture and manufacture.

Letchworth a Private Experiment

People are apt to assume that model housing schemes can only be carried out by philanthropists and governments with unlimited resources. The Letchworth experiment was initiated by a number of men, including Ebenezer Howard, the founder; the late Sir Ralph Neville, a judge; George Cadbury; and Alfred Harmsworth, as he then was, now proprietor of "The Times," who put a little money into the scheme at the start.

Altogether, we had little more than $500,000 when we started out to build that town. The whole of the capital that has been raised in connection with it does not amount to more than $3,000,000. That money is now beginning to receive dividends which are limited to 5%.

The main point I wish to make about Letchworth, as an illustration of practical housing, is that when you do a thing properly; when you apply social science to the development of the social forces of industry as you apply physical science to the actual operations of your industrial plants, you can secure equally good results.

In other words, the way to bring about good results in connection with housing is to do the thing in the right way, although it needs more courage, vision and trouble at the outset. I think that is one of the things we have to learn in connection with our housing experiments in Canada, if we are to be practical: That it is far better to do the thing in the right way, even if at first it appears to be more costly.

Hampstead Garden Suburb

Hampstead is a suburb of London. The Hampstead Garden Suburb is the creation of a woman, Mrs. Barnett, wife of Canon Barnett, who spent a great many years in the east of London, and came to the conclusion that the way to solve the housing problem in the slums was to get the people out into the country, out into the suburbs. So she

built a garden village at Hampstead, where she mixed the rich and the poor; for, as she said, it was as much for the benefit of the one as of the other.

Well Hall Model Village

At Well Hall, near Woolwich, there was built during the war a town of 6,000 people. This town, which was built in 1915, was brought into being and occupied within nine months, this by the slow English people at a time when the whole organization of the country was devoted to the manufacture of munitions of war, the raising and transportation of troops, and other war purposes. This and other schemes were carried out as the result of investigations made under Lloyd George, who wanted to find out how to increase the output of munitions. It was decided that to ensure reasonable hours of labor, comparatively good pay and, above all, good homes and contentment on the part of the worker, so far as his living conditions were concerned, was the best way to increase output.

If it is sound policy to build good houses and provide pleasant surroundings for workmen in the middle of a war in order to increase the output of munitions, it is just as sound a policy to provide good conditions and good surroundings and to bring about contentment among our workers in order to increase the output of production to meet competition with other countries in time of peace.

Practical in Peace-time Also

Under the war strain the British people were working at high pressure, and it would not have been unnatural to say to the people that, as patriots, they should be content with conditions that were unpleasant or unfavorable in the matter of housing. But it was considered to be better, even in time of war, to follow the bold policy of building permanent and healthy homes with agreeable surroundings.

What is wanted in the development of modern industry is not so much physical strength as nervous energy on the part of the worker, nervous energy and mental capacity to manipulate complicated machinery and to deal with difficult mechanical processes.

It is more important than ever before that we should have the worker living under conditions that will cause him to be contented and that will enable him to give the greatest efficiency to his work.

And in this respect the Well Hall experiment has a lesson for us. If it is good practical policy to build garden villages in time of war, it is equally a good practical policy to build garden villages and to improve housing conditions in times of peace.

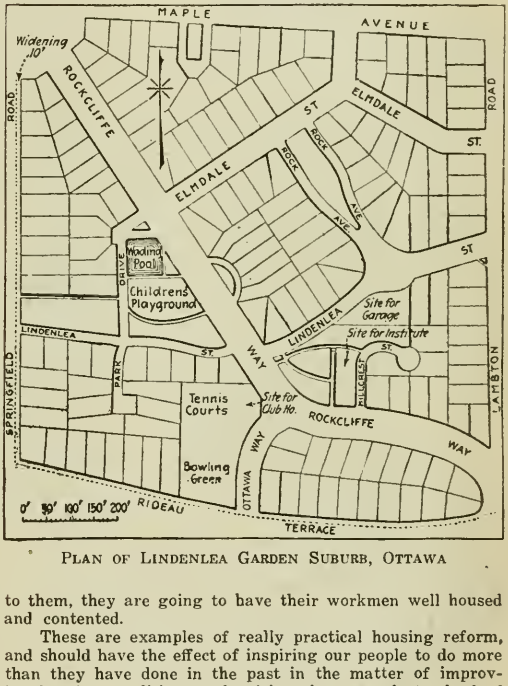
Therefore, I think we may congratulate ourselves upon the fact that the government of Canada and the provincial governments have taken the initiative in the matter of housing, with a view to dealing with the problem in the right way. Loans are made to the provinces for housing purposes. In this connection Ontario and its municipalities are heartily co-operating with a view to improving housing conditions. I am not going to deal here with the Canadian situation. I am simply trying to establish the value of good, sound methods of development as the really practical way of solving the housing question.

Inspiring Examples in Canada

I have endeavoured to illustrate some of the good examples of practical housing with the idea of suggesting to those who are dealing with this matter that they take no half-way measures, but go in for real, substantial improvements in the matter of raising the standards of housing accommodation. We are face to face with this condition in modern times: Men demand higher standards of housing at a time when costs are high, when labor and materials are expensive. But we must face that difficulty and try, by greater efficiency, to attain these high standards. We have to remember that to the extent to which we provide proper conditions, men will have greater earning power, and there will be greater efficiency and increased production.

I hope that the citing of these examples of British conditions has not produced the impression that I have endeavoured to contrast them with our bad conditions in Canada. We need the inspiration of what the "mother country" is doing to solve this problem; and we can take to heart the fact that in Letchworth, Hampstead and Well Hall, England has demonstrated one or two methods of dealing with the problem which are worthy of our consideration here. We have in Canada, as in the case of Grand 'Mere, Kipawa and Lindenlea (Ottawa), examples of proper attention to this subject which are equally good and equally inspiring.

At Lindenlea, Ottawa, we are carrying out a housing scheme under the Ontario Housing Act. At Lindenlea it has been proved that planning pays, and that when the land is properly planned great economies can be effected and ample recreation spaces provided. I think we shall be able to create there a suburb of Ottawa that will also be worthy of citing as an example. At Kipawa, on the Timiskaming river, the Riordon Pulp & Paper Co. are building a model town, which, I think, will also be an excellent example. Their houses for workmen are costing from $4,000 to $6,000. They have already erected 30 houses and are proceeding to build more. They are not content with shacks; they are not content with cheap houses; they recognize that even if it means a loss



PLAN OF LINDENLEA GARDEN SUBURB, OTTAWA

to them, they are going to have their workmen well housed and contented.

These are examples of really practical housing reform, and should have the effect of inspiring our people to do more than they have done in the past in the matter of improving housing conditions and raising the general standard of living among our working people.

[NOTE.—The land for Lindenlea was bought by the Ottawa Housing Commission, and the "garden suburb" was laid out under Mr. Adams' direction. Most of the houses will be detached and they will be erected on lots having a frontage of from 30 to 60 ft. The tract of land acquired has an area of about 22½ acres, and of this over 2½ acres, or fully 10%, has been set aside for parks, playgrounds and other open spaces, including sites for a community garage and an institute. There are 168 available housing sites. The land is somewhat rocky. The street system and lot subdivisions have been planned to effect economy in street construction as well as with an eye to the best possible appearance. As shown by the accompanying plan, there is a principal street, called Rockcliffe Way, laid out as a diagonal thoroughfare. This is 66 ft. wide along its entire length. Near one end there is a short connecting road called Ottawa

Way, from which a good view may be had of the Parliament building. The minor streets are of less width, varying with the probable future traffic, and are so laid out that for the most part the lots are regular in shape, although not always rectangular. Mr. Adams states that the total cost of the land was about $66,000. Incidental expenses of some $15,000 will be incurred. Streets will be macadamized to a width of 14 to 16 ft., and it is expected that this work will be done by the city. The lots are being sold for $340 to $600 each, or 12.8c. per square foot on the average, with a range of from 10 to 15c. Lots fronting on Rideau Terrace, which has already been provided with partial improvements, have been sold at an added price of 75c. a front foot. Most of the trees will be preserved. An effort is being made to ensure the placing of electric and telephone wires at the rear of the dwellings, so that the streets will be kept free from poles. This will mean that the street lighting will have to be arranged by underground wiring, which can be carried out inexpensively as compared with underground wiring for electric services to the dwellings.—EDITOR.]

Experiments Show Effect of Fineness of Cement

Results of Over 6,000 Tests of Concrete Cylinders, 9,000 Compression and Tension Tests of Mortar, and Several Thousand Miscellaneous Tests —Summary of Paper Presented to American Society for Testing Materials

By DUFF A. ABRAMS

Professor-in-Charge, Structural Materials Research Laboratory, Lewis Institute, Chicago

RECENT revision of the standard specifications for portland cement served to focus the attention of engineers on the function of fineness of grinding of cement in producing concrete of high strength and other desirable properties. An investigation of this subject has been under way at Lewis Institute for the past four years. Five series of tests have been completed; another series is now under way. These studies were made as a part of the investigations of concrete and concrete materials being carried out through the co-operation of the Portland Cement Association and the Lewis Institute at the Structural Materials Research Laboratory.

The portland cements used were from seven commercial mills. These plants represent the principal cement-producing districts east of the Mississippi River. Fifty-one different samples of cement were used. The cements were ground at the mill to four to seven degrees of fineness, which gave residues ranging from 2 to 43% on the standard 200-mesh sieve. In general, the aggregate consisted of sand and pebbles; in one series blast furnace slag and a light-weight aggregate consisting of burnt shale were used.

Nine Subjects Investigated

This paper covers compression tests on 6,125 (6 by 12-in.) concrete cylinders, 9,000 compression and tension tests of mortar, and several thousand miscellaneous tests. Strength tests of concrete and mortar were made at ages of seven days to one year.

Definite information has been secured on the effect of fineness of cement under the following conditions:—

(a) Effect of fineness of cement on the strength of concrete.
(b) Quality of concrete, using different cements.
(c) Effect of the quantity of cement used.
(d) Effect of consistency of the concrete.
(e) Effect of size and grading of the aggregate.
(f) Variation in the type of aggregate.
(g) Effect of age of concrete.
(h) Elongation and contraction of concrete.
(i) Effect of fineness of cement on workability of concrete.

The following may be stated as the principal conclusions from the tests:—

1.—There is no necessary relation between the strength of concrete and the fineness of the cement if different cements are considered.

2.—In general, the strength of concrete increases with the fineness of a given lot of cement, for all mixes, consistencies, gradings of the aggregate and ages of concrete. The cements with residues lower than about 10% were inclined to give erratic results in the strength tests. One lot showed an abnormal increase and two others a pronounced decrease in strength, as compared with the other tests on coarser cements in the same lot.

3. For residues higher than 10%, the strength of concrete varies approximately inversely as the residue on the 200-mesh sieve.

4.—Fine grinding of cement is more effective in increasing the strength of lean mixtures than rich ones.

5.—Fine grinding of cement is more effective in increasing the 7-day strength of concrete than at ages of 28 days to 1 year.

6.—For the usual range of consistencies, the effect of fineness of cement is independent of the consistency of the concrete. The rate of increase in strength with fineness is lowered for very wet mixtures.

7.—Ordinary concrete mixtures at 28 days show an increase in strength of about 2% for 1% reduction in the residue of the cement on the 200-mesh sieve. At 7 days, 3 months and 1 year the corresponding increases in strength are about 2.5%, 1.7% and 1.4%.

8.—The decreased benefit of fine grinding of cement with the age of the concrete does not bear out accepted opinion that the coarser particles of cement do not hydrate, but indicates that the principal result of finer grinding is to hasten the early hardening of the concrete.

9.—For the richer mixtures and the consistency necessary for building construction, the fineness of the cement has no appreciable effect on the workability of concrete as determined by the "slump" test. For leaner mixtures and wetter consistencies, the finer cements showed a somewhat greater "slump" than the coarser cements.

10.—The normal consistency of cement is increased with fineness of grinding. About 0.1% of water (in terms of the weight of the cement) must be added for each 1% reduction in residue on the 200-mesh sieve.

11.—The time of setting of the cement is shortened with finer grinding. In some instances initial setting time with the Vicat needle was shortened to 5 to 10 minutes.

No Effect on Density

12.—The unit weight of cement decreases with fineness. For the cements used in these tests the weight varied from 76 (residue of 2.4%) to 108 lbs. per cu. ft. (residue 43.3%). For the usual range in fineness, the weight is lowered about ¾ lb. per cu. ft. for each 1% reduction in the residue on the 200-mesh sieve.

13.—In using 94 lbs. per cu. ft. as a uniform basis for proportioning the cements in these tests, the actual volume of cement in a batch *of the same mix* varies about 35%. If the mixtures had been proportioned in a manner that would have given a uniform *volume* of cement, the resulting concrete strength would not have been so favorable to the finer cements.

14.—The fineness of cement has no appreciable effect on the yield or density of concrete.

(Concluded on page 448)

BELLEVILLE, ONT., WATER SUPPLY*

PRIOR to 1918 the city of Belleville, Ont., with a population of about 13,000, was supplied with water by two steam pumps and one electrically operated pump, the latter being used only for domestic supply. On account of the growing demand for water, the increased cost of pumping and the condition of the steam pumps, which had been operating many years, it was decided to install new electric pumps and as soon as a duplicate transmission line could be built to the pumping station, to discard all the old pumping equipment.

The pumping station is west of the Moira river (which flows through the centre of the city) and is about one mile from the central business district. The supply is pumped through a single 16-in. main, about one mile long, to a standpipe of 360,000 gals. capacity and to the distributing mains. In the new layout, provision was made for a duplicate 16-in. supply main to be installed at a later date.

In order to properly accommodate the new electric pumps and control apparatus, the old steam pump room was enlarged and provision was made for placing the starters from the motors on a gallery to which was also carried the main valve stems and valves in the priming piping. This gallery extends around the sides of the pump room. On the back wall of the gallery is mounted the 550-volt bus disconnecting switches, meters, etc. The bus is sectional so that normally some of the pumps can be fed off one circuit and some off the other, or if necessary all the pumps can be fed off either circuit.

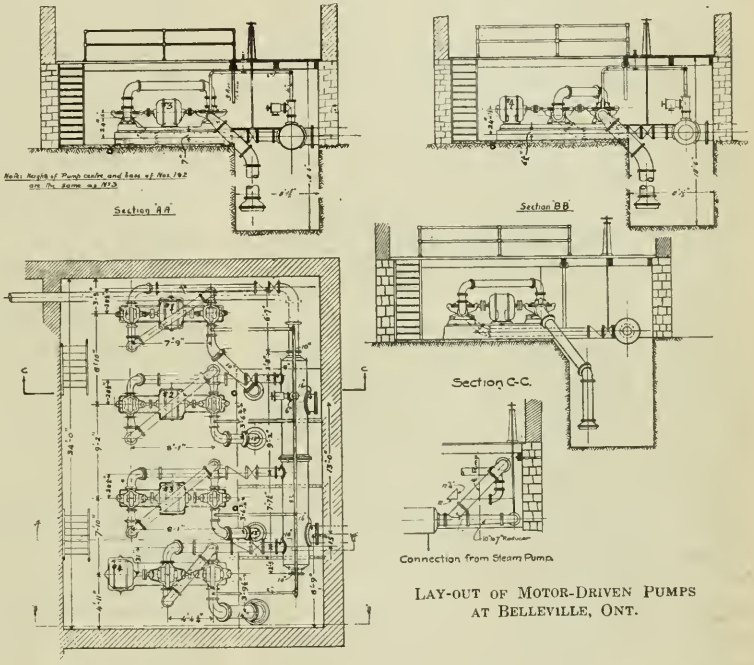
There are four pumps, one of 800 gals., driven by a 100-h.p., 3-phase, 60-cycle, 550-volt, 1,800 r.p.m., induction motor; two of 1,100 gals., each driven by a 125-h.p. motor; and one of 1,560 gals., driven by a 150-h.p. motor. All the motors are of the squirrel cage type. The pumps are designed to operate most efficiently at a head of 250 ft. (108 lbs.). They are also designed to deliver about two-thirds their normal capacities at a head of 325 ft. (141 lbs.) for fire purposes, this high pressure being required to overcome the friction in the long 16-in. main and still give ample pressure in the central business district. The small deficiency in volume for fire service can be made up by the future addition of pumps driven by gasoline engines. The pumps are all two-stage split-stage type; that is, two single-stage pumps connected in series, with the motor in the centre except in the case of the largest pump, where the motor is at one end.

The intake, which extends some distance into the Bay of Quinte, delivers through screens to a suction well in the pump room, from which the pumps discharge to a steel header located at the top of the suction well. The present 16-in. delivery main is connected near one end of this header and provision has been made for connecting a future 16-in. delivery main near the opposite end. All the water pumped is measured with a Venturi meter.

Preliminary plans have been drawn providing for a new intake and suction well from which low-lift electric pumps will deliver the water to rapid sand filters, which in turn will discharge to a clear water reservoir and to the present well.

When deciding upon the head and other characteristics of these pumps, and the location and type of electrical equipment, consideration was given to the possibility of using the pumps and equipment in a more complete water treating and pumping plant.

The transformers by which 550-volt service could be supplied to the present or future pumps from lines operating "Y" or delta connected, have been located temporarily on a pole-type structure just outside the pump house. Permanent installation of this equipment will be decided upon when a more adequate water treating and purifying system is being installed. Two independent power lines are being built to serve this station.



LAY-OUT OF MOTOR-DRIVEN PUMPS AT BELLEVILLE, ONT.

A comparison of the cost of pumping for 1916 and 1919 shows a saving for 1919 of $750. Part of the domestic pumping in 1916 was handled by the old electric pump and the remainder by steam, 600 tons of coal at $4.75 per ton being used. In 1919 all the pumping was done by the electric pumps.

*From the October, 1919, Bulletin of the Hydro-Electric Power Commission of Ontario.

The Engineers' Club of Peterborough, Ont., will hold a dinner this evening at the Empress Hotel, Peterborough. After the dinner the club loses its identity and becomes the Peterborough branch of the Engineering Institute of Canada. This dinner will therefore mark the inauguration of the new branch as well as the termination of the old club.

Sir Adam Beck was heartily endorsed last week at a meeting of the Municipal Hydro-Electric Association of Ontario, and he was urged to continue as "Hydro" chairman. Sir Adam had threatened to resign on account of his defeat in the recent provincial election, as he thought that the "Hydro" chairman should be a member of the legislature. The Association stated that a seat would be found for him, and urged Sir Adam so strongly to continue his work that he found it impossible to resist the popular pressure upon him to remain in office.

FINANCIAL STATEMENTS AN AID IN PROCURING CONTRACTS*

By Daniel J. Hauer
Construction Economist

A DECADE or two ago, a contractor who had just finished a large contract upon which no money had been made, and with his plant or outfit tied up so he could not move it, put about $250 in his pocket and went into an adjoining state to procure a new contract and get another start in his business. By sheer force of character and keen judgment, together with diplomacy in talking to and handling the engineer and other officials of the company letting it, he obtained a contract for more than half a million dollars of work. With this as an asset he was able to borrow ample money to get the job under way quickly.

A number of such examples of securing valuable contracts with little or no capital, and carrying them to completion upon a shoestring, could be cited from the experience of the writer and his friends. It still can be done in some cases, but it is the exception to-day rather than the rule.

Financial Responsibility Now Necessary

The first step in obtaining a contract under present-day conditions is a matter of finance, a setting forth of the contractor's assets. Certified cheques must be used for bidding, bonds made to qualify before figuring, and for some public contracts a certificate must be furnished before bidding that a bonding company will make bond should the contractor get the job. There are even cases in which a contractor must show his responsibility to the owner before the contract is awarded.

Finances thus become the basis of procuring nearly all contracts, and this means that the modern contractor must look closely after his financial standing in the business world. With ample capital this is seemingly an easy matter, yet many contractors who possess large capital do not always enjoy the best of credit or possess the financial standing of those with less means, due to the fact that they are not careful of their credit, and think they are always likely to be in a position of meeting their obligations with ease.

Benjamin Franklin told how he borrowed money and built up his credit when he did not need money and could pay cash, in order to have a good line of credit extended to him when his needs were urgent. This is a valuable lesson in which all contractors can find profit.

Credit is obtained by two methods to-day. One is by means of statements showing assets and liabilities, thus disclosing the net worth of a growing concern. The second method is by means of references. In this last, personal integrity and the esteem and confidence in which a man is held counts for much. In most cases these two methods go hand-in-hand, and the second is frequently the result of the first. In spite of this it is quite surprising how many contractors refuse to make statements of their financial condition.

Even Large Contractors Borrow

Only recently, as the writer was giving a statement to the solicitor of one of the large national mercantile agencies, the solicitor remarked upon the fact that a large per cent. of contractors refused to make statements, with the result that their standing was greatly reduced and their credit limited. Definite knowledge of a man's standing, even though he has only a few thousand dollars, has been proved better than meagre information regarding a man who may be worth more.

Take the question of deposits on bids, for example. If the cheque is only a few hundred dollars, almost any contractor can furnish it, but if some thousands are demanded, even the contractor who is conducting a large business may not be able to spare the sum, and must arrange to borrow the money. As this is written, an eastern state is asking for a $25,000 certified cheque with a bid. Even if a bidding bond is used instead of a certified cheque, the bonding company will want to know the financial condition of the applicant.

This likewise is true if a bond must be obtained when a contract has been awarded. If there is a maintenance clause or guarantee to the contract, the bonding company will want to know if the contractor is financially strong enough to live up to the contract he is about to make.

If the engineer, architect or owner is careful to whom he lets work, a close investigation will be made of the standing and reputation of the successful bidder. In some cases this is done before bids are asked from contractors. The only way to meet this demand for information is to have carefully prepared reports of a contractor's standing in the hands of commerical agencies and of his banker. A great saving of time will thus be effected.

Money frequently must be borrowed from banks to start new contracts, and if close relations are to be maintained with a banker he will demand information in regard to the general business policy of the contractor and what his net worth is from time to time. Some people are not favorably impressed with bank references, while others prefer them. In many cases large contracts have been captured by aid of letters from bankers saying the contractor was able to handle the transaction, or else that they were willing to give him financial assistance. In many cases during the world-war, the national government demanded information from contractors and their bankers before awarding contracts.

Lost Municipal Paving Contract

There is a growing tendency among state and city governments to look into such details, and some few are asking for this information direct from the contractor. On the other hand, most of this information is gleaned from outside sources, and frequently to the detriment of the contractor. Only during last spring the writer knew of a city refusing to award a paving contract to the lowest bidder on account of meagre information about the financial standing of the contractor.

Thus, to obtain contracts, the first consideration for a contractor is to set his house in order. He must have financial standing in order to bid, in order to get the contract after bidding, in order to make bond, and in order to purchase plant from manufacturers, especially in lease sale agreements. The making of a financial statement does not mean the actual putting of capital into his business, but it does require the furnishing of accurate and detailed information to insure confidence. Thus, indirectly it increases his capital, for by it he may obtain contracts, valuable assets in themselves, and also credit to purchase machines and supplies far beyond what actual capital would supply. It establishes more firmly his position in the business world.

*From "Successful Methods."

The John ver Mehr Engineering Co., Ltd., has moved from 154 Simcoe St. to 32 Church St., Toronto.

Declaring that high officials of the American Federation of Labor are responsible for "tendencies that threaten the foundations of the government of the United States," a union of draftsmen employed in the U.S. Treasury Department withdrew last week from the American Federation of Labor. The movement is part of a general campaign to secure withdrawal by all government employees' unions.

The Milwaukee Chapter of the American Association of Engineers has submitted a schedule of salaries for the various engineer employees of the city to the city council. The council did not take definite action on October 21st, when the request was presented, but will do so inside of a week or two. The following positions are the principal ones affected by the proposed increases:—Chief engineer of sewers, office engineer of water department, field engineer of water department, chief draftsman, division engineer of street construction, and chief estimating engineer.

AIR LIFT PUMPING*

By Chas. J. Deem
Hydro-Pneumatic Engineer, Harris Air Pump Co., Chicago

IF I had been called upon to write this paper some 12 or 15 years ago, I could have conscientiously and honestly told you many things that I then believed, which time has proven might not always be the case, in regard to air lifts. In that early day of air lift pumping first entering into the commercial field, there were a great many conditions surrounding its operation that were unknown to the manufacturers of the lifts themselves.

It has been charged by many, and more especially by engineers, that the manufacturers of air lift pumps wish to surround their product with mystery. I can truly say that this is not the case. The manufacturers of air lift pumps, like any other trades-people, wish to sell all of their product that they can, and will willingly give all the information regarding its operation that will make it more popular in the deep-well pumping field. However, they are limited in this desire from the fact that no *master formula* has as yet been devised whereby infallible rules may be laid down for the proper designing of any and all installations, without any regard for the conditions that exist in the wells.

The Individuality of Wells

Some 15 years of experience have taught me that in many instances wells are just as individual in their actions as are persons. Therefore, a properly designed air lift installation, operating satisfactorily in one well, might give entirely different results when installed in another well which, to an inexperienced operator, might seem to be identical.

While experience is not absolutely essential to the pumping of water from deep wells by the means of compressed air, yet I know of no engineering field where experience counts for more or is more essential than in air lift pumping.

Some of our best engineers have branded air lift pumping as a system sadly lacking in economy, but in such cases their judgment has been based upon results obtained from improper methods of piping, in connection with inefficient air compressors. Many have also become convinced that there is no special merit in the patented air lift pumps, that home-made devices will answer the purpose just as well. However, in all my years of experience, I have never yet seen one of these home-made lifts over which a patented pump would not give excellent returns on the small amount of money invested in it.

Contrary to a popular belief, the compressed air discharged through an air lift pump does not blow the column of water upward after the first discharge. When the static head is lifted from the working head of the well by the first inrush of air, the water is forced out of the pipe in a solid column. After that, the compressed air passing through the pump reduces the specific gravity of the water in the discharge line of the pump. This consequently moves upward by the expansion of the air bubbles, aided by the greater weight of the solid column of water surrounding the discharge line.

Should Avoid Large Bubbles

In an economically designed air pump, it is imperative that the formation of large bubbles of air be avoided, for these have a tendency to rush upward without lifting the proper amount of water for the stored energy that they contain. Therefore, the pump should divide the air into small streams or jets, creating as many small bubbles as possible in order to give the best economy. The slip of these bubbles constitutes the chief loss in the energy of the air lift. It is figured that this varies as the square root of the volume of the bubbles. Therefore, the smaller the bubbles, the more efficient the air lift.

Of course, one of the foremost things to be considered in the installing of a pumping plant is its efficiency. I presume there is no one word in the English language to-day that is used more in manufacturing and engineering circles than the word efficiency. It is a good strong word, but may be figured from so many different bases of calculation that all conditions in connection with the apparatus must be thoroughly understood before the percentage of efficiency that is claimed for it can be valued. The only true way I know to figure the efficiency of a pumping plant is that at the end of the year the column in the ledger headed "operating costs" be added up and the results calculated from its total. In this column we will also find, if we note down the items such as repairs, break-downs and their attendant losses, and read between the lines the worries that were caused thereby, we can also determine just how efficiently the system has or has not caused trouble.

Workable Efficiency Required

In travelling over the country I find that water works superintendents and manufacturers are more and more demanding workable commercial efficiency from their pumping machinery. They realize that by installing some very closely adjusted high-speed apparatus in their wells, they may be able during its short life to pump water very cheaply per thousand gallons, but that in about nine cases out of every ten, such a pump is sure to cause trouble sooner or later, more often sooner; and that the small amount saved per thousand gallons pumped during the course of the pump's successful operation, is far more than offset by repairs, shut-downs and pulling of wells.

To give some idea of the faith that the underwriters of the country have in the reliability of the air lift system, I will, with Mr. Judd's permission, tell his experience with them in reference to his discarding of deep well pumps and the installing of air lift systems in the city wells here in Mason City. The Board of Underwriters in Chicago granted him 30 points on the key rate of insurance for the fire protection the increased yield of the wells would afford the city, and they gave him 130 points because of the reliability of an air lift pumping system. This is something that should be weighed very carefully, for if there is any institution in the wide world that figures from exact statistics, it is the underwriters. They do not guess, they know.

As I said before, no one has yet been able to figure a master formula for the installation of the air lift any more than has some noted doctor been able to write a master prescription that will cure all diseases to which flesh is heir. However, the manufacturers of air lift pumps have at quite a great expense gathered data from laboratory tests and field experience that enable them to construct formulas which cannot be universally applied to all conditions, yet can define and introduce certain rules which enable them to calculate the requirements for a proposition when the exact data are known.

Exact Data Sometimes Lacking

When exact data are lacking, conditions are usually *assumed* and a lift installed. Then, from results obtained, the engineer, by basing his judgment on experience, can proceed to pipe up the well so as to get economical results. To give an illustration of this:—

Some years ago I installed an air lift in a flowing well on a ranch in southwest Texas. The well was 8 ins. in diameter, about 600 ft. deep and flowed about 20 gals. per min. The owner of the ranch had only a small compressor, its maximum capacity being 30 cu. ft. of compressed air per minute. A 6-in. pump was installed 2 ft. in the well, and this 30 ft. of air delivered to it. The head of the well dropped 20 ft. from the surface and the well yielded 530 g.p.m., accurately measured over a knife-edged weir. Of course, this was phenomenal. Never before or since have I seen such a small volume of air deliver so much water from a deep well.

Only the week before last, at Fort Dodge, Iowa, we installed a 6-in. pump in a flowing well located on an island in the Des Moines river. The well was 8 ins. in diameter, 500 ft. deep and flowed 21 gals. per min. The same size pump was located 200 ft. from the surface, and we delivered to it 200 cu. ft. of air. The working head of the well dropped 150 ft. from the surface and yielded 80 g.p.m. This proved

*Paper read before the Iowa Section of the American Water Works Association at Mason City, Iowa.

to be a very uneconomical installation, yet, to all outward appearances, the conditions in the second well were the same as those in the first, and the results almost beyond comparison.

It is in this second well that experience would have been necessary to have properly piped it up had the city decided to use it. However, they had plenty of other water available, so the well was abandoned. But an air lift could have been installed in it in such manner that, figuring from the current input at the motor of the compressor to the water discharged in the reservoir, it would have shown 30% efficiency. This could have been obtained by installing a 3-in. air lift and taking 50% submergence, or, in other words, by placing the lift as far below the working head of the well as we were going to lift the water. This would have yielded one gallon of water for 0.63 of a cubic foot of air at 67 lbs. pressure.

Misleading Results

Of course, the starting pressure in this well would have been greater than that of the other wells of the system, yet this could have been offset by the use of an auxiliary air line to lift the head of the well. Had the original installation in this well been let stand, anyone wishing to speak disparagingly of air lift pumping could have in all honesty cited it as an expensive mode of pumping water. On the other hand, some manufacturer wishing to extol the virtues of his pumps, might have honestly printed a glowing advertisement of the results obtained in the well first described. Both would be equally misleading. The first is a result from what might be termed a freak well, while the installation of a 6-in. pump in the second well would be improper for the best results obtainable by the air lift system. I only cite these two wells to illustrate my point that each well forms an individual problem and that the same installation in all wells would fail to pump them properly just as would the same medicine fail to cure all men suffering from disease.

One reason why the air lift pump proves valuable in many parts of the state of Iowa, or for that matter in any other part of the country where the water contains as much iron and sulphur as it does in this locality: When a well is pumped by air, the water undergoes a complete aeration, for the air and water are mixed under pressure and this tends to throw off the sulphur gas and precipitates a great deal of the iron. One of the principles on which the iron-breaker works is aeration.

Also, many of the wells in this part of the state pump a great deal of sand, and as the air lift has no moving parts in the well, grit has no effect upon it. Any number of wells may be pumped from a central plant and there is no limit to the quantity of water that can be handled, and with a properly designed system, the extra cost of pumping wells located a mile from the power plant is not material. It has been stated that an air lift system requires little or no attention aside from keeping the compressor in proper running order. While this is practically true, and cited as one of its many advantages, yet sometimes it works to a disadvantage, because it will continue yielding water for years without giving any trouble, yet there are times when the system becomes unbalanced and the working heads of the wells recede (which changes the percentage of submergence), thereby reducing the yield of the well and increasing the amount of air required.

If the wells were checked up once or twice a year, and changes made to meet the new conditions, a great deal might be saved in operating cost. Sometimes very little things cause quite a great loss in economy. Not so long ago, I was called to a plant where a battery of five wells was being pumped from one compressor. The compressor at its maximum speed was barely large enough to pump the amount of water required. The operator told me that when the plant was first installed it gave excellent results. But there had been a decided falling off in the yield of the wells. The system was well designed and should have given good results. Upon investigation I found that two of the wells were much weaker than the other three and that they operated at about 15 lbs. less pressure than the other wells. When the engineer had balanced the system, he had set the regulating valve at the well head of these two weaker wells so as to admit only enough air to pump the water that they would economically yield, and, of course, had left the valves wider open on the strong wells.

When starting the system, the operator discovered that many times these two weak wells did not come in. Their static head being the same as the stronger wells, and therefore being supplied with much less air, did not start so easily. In order to overcome this he had very thoughtlessly taken a wrench and opened the valves of these two weaker wells. Any force follows the line of least resistance and the larger part of the volume of air rushed into the weaker wells, where it could not lift the amount of water that it could have done in the stronger wells. Therefore the system was out of balance and giving poor results, through no fault of the air lift or the man who installed it. When air lift systems are excessively costly to operate, I think it might safely be concluded that there is a good cause, and that the chances are that the trouble might be easily removed.

A great many mistakes are made when installing air lifts, especially by novices in the business, in reference to the size of the pump to be used to deliver economically a certain volume of water. In order to make that as plain as possible, I will give a concrete example:—

For instance, if we wanted to lift 150 g.p.m. from a well with a working head 80 ft. below the surface, the most economical pump to be installed would be a 3½-in. lift at 65% submergence. Under these conditions this pump should yield one gallon of water for every 0.3 cu. ft. of air at 67 lbs. pressure. As you can easily figure, the pump would be located 229 ft. from the surface. Now, suppose instead of being able to get 65% submergence, we can only get 40% submergence. In order to deliver 150 gals. per minute under these conditions a 4½-in. pump should be used, and one could expect a gallon of water for every 0.59 cu. ft. of air at 25 lbs. pressure.

By a little figuring one can ascertain that it required one and one-tenth more horse-power to raise the water in the second instance than it did in the first, and I gave it, hoping to be able to show that even though conditions be vastly different in various wells, a properly designed air lift can be made to yield good results. But, of course, there are places and conditions under which some other type of pump should be used.

As you can note from this example, as the submergence decreases, the size of the discharge line should increase. But this is only a general rule, and the conditions in the well to be pumped entirely govern the ratio of the change to be made.

Variable Discharge Lines

Of late years some firms have been advocating a variable discharge line. I mean by that, some firms wish to start with a smaller pipe and expand toward the point of discharge, the theory being that by allowing the compressed air more space in which to expand, it will lend more of its energy toward lifting water. On the other hand, some firms advocate turning this type of installation upside down, as it were; that is, they reduce the line toward the point of discharge, the theory being the same as the reason for choking the muzzle of a rifle in order to keep all the gases behind the bullet until it leaves the barrel.

Of the two systems, so far as observation has gone, the latter is to be preferred. I have seen it produce excellent results under some conditions; that is, by getting more water by greater economy than would be possible to get from a uniform discharge line made of our standard pipe sizes. I suspect that the friends of the expanded discharge line system will challenge this statement and point to some installations which they claim to be very successful. I have seen one or two of these, but they have been invariably installed in excellent wells that yielded large quantities of water very economically, not because of the system of expanding the discharge line, but in spite of it. However, improvements are being made in the system of piping, and each year shows more practical results than the preceding one.

Another improvement in the air lift system that I wish to mention briefly is what is known as the booster pump. This pump, or tank, is located on the well top and automatically separates the air and water as it is discharged from the well, retaining just enough pressure from the separated air to force the water to the point of discharge. This is indeed a great improvement when the water must be transferred long horizontal distances toward the point of discharge. This point may be at the surface or at an elevation. Hitherto when horizontal distances had to be considered, unless the water was delivered to an elevated tank and allowed to flow by gravity, the air would get ahead of the water in the discharge line, thereby materially reducing the efficiency of the system. However, the booster very efficiently overcomes this condition.

I have given no tangible data on the air lift, but from the varying conditions that exist in all wells, any statements regarding the air lift system as a whole must be of a general nature. Some manufacturers have, at no little trouble and expense, conducted exhaustive systematic tests in natural wells, or in artificial wells constructed for the purpose of maintaining any desired submergence by feeding water into them. The data that they thus gained is authentic for the conditions under which it was gathered. However, in the field nature does not make a habit of supplying her wells with water by pouring it in at the top. So we revert to the same premise from which we started. That is, each well presents a separate problem.

Another thing that has materially aided in the efficiency of the air lift system is the perfecting of air compressors by the various manufacturers. The standard compressors now offered on the market in nearly every instance operate on from one-third to one-fourth the horse-power that was required by the machines built some ten or twelve years ago. Not only is the economy of these machines much greater, but also the mechanical parts have been greatly simplified, thus bringing the air compressor into the realm of most economical machines.

U.S. ENGINEERING COUNCIL'S COMMITTEE ON CURRICULA OPPOSES PRESENT ADOPTION OF SIX-YEAR ENGINEERING COURSES

UNDER date of August 21st, 1919, the secretary of the American Institute of Electrical Engineers referred to the U.S. Engineering Council a portion of a report presented at a meeting of the Development Committee of that institute. The portion of the report so referred to the Engineering Council read as follows:—

"There is a universal recognition of the fact that engineers do not participate as actively or as prominently in public affairs as they should, and that both the public welfare and their own individual advancement would be promoted if this condition could be rectified. There are two general reasons believed to be responsible for the existing condition: One, a lack of any general organization of engineers which would facilitate their co-operation; and second, too great technical specialization in the engineering curricula of our technical schools and colleges, which tends to narrow the vision of the engineering student and start him on his career with an exaggerated idea of the importance of specialization and an insufficient appreciation of the part he must play in public affairs. The second reason, namely, a possible modification of the engineering curricula of our technical schools and colleges, while perhaps of underlying and fundamental importance, was nearly crowded off the Lake Placid program by the press of other matters. It was, however, the unanimous view of the members attending the sessions that this matter should receive early and thorough consideration by the institute, and the following preamble and resolution were presented and adopted:—

"'As the individual engineer cannot look for greater public recognition or individual advancement than his training and fitness warrant;

"'And, in the belief that the bigger development of the profession consists in broader social and public service by publicly minded engineers;

"'Recognizing that on the one hand young engineers are employed for too long a period at work which does not stress their capabilities, and, on the other, that the demands of industry for ever-increasing numbers of technicians must be supplied;

"'And having in mind the excellent precedents established by the medical and legal professions;

"'This committee would welcome the establishment at the earliest date practicable of a normal six-year collegiate course in engineering, two years of which at the least should be devoted to training in the humane arts and sciences, including, for example, political science, economics, history and general letters, the last four years being devoted to sound training in the sciences and in only the fundamentals of diversified engineering.

"'With or prior to such a development we would endorse a program for the marked extension of vocational training in the industrial centres in order that the needs of industry may be met.

"'To the accomplishment of these ends this committee requests the appointment of representatives to serve on a Joint Committee of Engineering Organizations to promote such a national educational program as shall provide for the future necessities of the engineering profession consistent with the needs of society.'"

This report was referred by Engineering Council to its Committee on Curricula of Engineering Schools. At a meeting of that committee held October 15th, the recommendations of the Development Committee of the American Institute of Electrical Engineers were considered, and the following report was sent to Secretary Flinn of Engineering Council:—

"While your committee is not prepared to recommend a six-year course for the colleges of engineering, your committee calls particular attention to the fact that a six-year course was inaugurated at Columbia University some few years ago, practically on the same plan as in the case of the schools of law and medicine, the technical studies of the engineering portion of the course being concentrated on the last three years and based upon three years devoted to studies leading to the B.A. degree.

"The Massachusetts Institute of Technology is also conducting a six-year course in engineering, this being in addition to, and without interference with, the regular four-year course. A somewhat similar program, although perhaps less formal, is followed by the majority of the students in the Harvard University Engineering School, who first take their bachelor's degree in Harvard College, followed by two years in the engineering school. This problem is also being studied and experimented on by other universities.

"Your committee suggests that, as these practical experiments with the six-year course will furnish information not now available, any final recommendation can well be deferred until the results of these experiments can be studied and appraised.

"Your committee is now prepared to report unfavorably on the proposition to substitute the six-year course in place of the four-year course generally in the colleges.

"Your committee strongly endorses the proposition to extend and enlarge the facilities for vocational training, particularly in the great industrial centres; this educational work, however, to be carried on without interfering with the courses in engineering.

"Your committee also favors universal military training under proper regulations.

"Your committee does not agree that military training and vocational training should be combined, except so far as the vocational training would be found to be naturally involved in the military training."

AN EXPERIENCE WITH A BROKEN 24-IN. WATER MAIN*

By S. L. Etnyre
Superintendent, Council Bluffs (Iowa) City Water Works

MOST water works men, no doubt, have had more or less experience in the breaking of water mains, and yet I am sure they are ever interested in finding out what the other fellow's experience has been; to know what effect such a break had upon the service; damage done by the water; cause of the break; etc. Before entering upon our recent experience with the blowing up of a 24-in. main, I will briefly describe its history and its importance in the operation of the plant:—

This main was laid on Broadway, in the year 1882, running from the Broadway Pumping Station at 37th St. to 21st St., a distance of 8,500 ft. From this point to 8th St. is 5,323 ft. of 20-in.; thence to the high-level storage reservoirs, 5,200 ft. of 16-in. Up to 1915 all the water for the city was supplied through this 24-in. pipe. On account of the importance of this main, and owing to the fact that with increased consumption the pressure materially increased, it was found necessary to lay an auxiliary 16-in. main from the Broadway Station to 21st St., and this was completed in 1915. With the reservoirs' storage, it was calculated that the 16-in. would supply the city in the case of any mishap to the 24-in. Two 24-in. valves were cut in the Broadway main and a drain laid into the sewer from the main at its lowest point.

Four Breaks in Thirty-Five Years

In 1884 the Broadway main broke at 30th St., a section 12 by 24 ins. blowing out at the bottom. No flaws were noticeable. In 1908 this main broke at 28th St. A triangular section 18 ins. at the base and 6 ft. long blew out at the side. No flaws were noticeable. In 1909, on the west side of 34th St., the pipe broke as if pulled apart. No flaws were noticeable.

The normal pressure carried by this pipe was 105 lbs. Our last break took place October 6th, 1919, on the east side of 34th St., a 12-ft. section splitting on its side for its entire length. The pressure dropped suddenly from 125 lbs. to 17 lbs. The volume of water escaping through this break was enormous, resulting in the drop of pressure all over the city, and many parts—even at moderate elevations—were without water until the valves were closed. From measurements taken at the high-level reservoir, making allowance for the normal city consumption, over 1,000,000 gallons had run out through this break. Fortunately, however, there was no material damage to private property.

The pressure chart at the pumping station plainly showed the time of closing the valves. Some time was lost in this work by the breaking of a 24-in. valve stem. Pumping to the city through the 16-in. main was started immediately upon the closing of the valves. The drain valves into the sewer were then opened, and when the pipe was broken into, it was found to be entirely free of water. It is also remarkable that all valves proved to be water-tight. The defective section was broken up with sledges and replaced with a new length, and the main was ready for service within 15 hours from the closing of the valves. During the time the repairs were being made, less than 1% of the consumers of the city were without water, and but for the breaking of the valve stem above referred to, less than one-half of the 1% would have been without water.

Original Casting Well Preserved

Pieces of the broken pipe show that the original casting is well preserved, although a casting defect is indicated at one point. A careful examination of the fracture, however, does not warrant the assumption that this condition prevailed to any extent. The thickness of the shell along this line of fracture was a good average with the rest of the pipe, being approximately 1 in. The question that now naturally suggests itself is, "What was the reason for this break?" Of course, the water pressure was partly responsible, but that is not the complete answer. We know by looking at the pressure chart that it was not caused by "water hammer." The thickness of the shell seems adequate for the pressure it had to carry; it was a good grade of metal and no evidences of serious flaws on fracture line or elsewhere were found when broken into small pieces.

*Paper read before the Iowa Section of the American Water Works Association.

UNIQUE MEMBERSHIP CAMPAIGN LAUNCHED BY AMERICAN ASSOCIATION OF ENGINEERS

WITH arrangements made for the largest sales organization that ever sold an engineering commodity, the American Association of Engineers announces a membership drive during the first two weeks of December. A letter from the secretary of the association says:—"There will be 9,000 salesmen, 90 branch sales offices, and 4 district sales offices. That summarizes the sales organization of A.A.E. If every salesman makes a sale, that is 9,000 sales; if every branch office turns in 100 applications, that will be 9,000 more.

"The method to be employed is similar to that used in obtaining subscriptions to the Liberty loans.

"The 90 clubs and chapters will divide their members into membership teams, each with certain territory to cover, and under the supervision of a team captain. The drive will be handled for each chapter by a drive commander who will keep in direct touch with the national headquarters of the association by telegraph. He will make telegraph reports of the number of applications obtained each day. A force will be maintained at the national headquarters to tabulate the returns and to advise the chapters of their standings.

"For the purpose of competition, chapters and clubs will be divided into two groups: Those having more than 100 members at midnight on December 13th, when the drive ends, and those having less than 100 members on that date. A special gavel will be presented to the chapter or club in the latter group which has the greatest percentage of increase of membership during the drive. Of the chapters having 100 or more members at the end of the drive, official A.A.E. colors will be presented to the one that has obtained the greatest percentage membership increase during the drive.

"The three members securing the greatest number of applications between the first and thirteenth of December, inclusive, will be awarded respectively a life membership in A.A.E., a collection of books to the value of $100, and a watch of the value of $50. The captain of the membership team in each chapter or club which obtains the greatest number of applications of all the teams in that chapter or club, will be awarded a solid gold, engraved, A.A.E. watch fob. Individual chapters and clubs may award special prizes to their members. The referee in the drive is Isham Randolph, consulting engineer of Chicago.

"With a membership of almost 8,500 at the end of October, it is probable that the American Association of Engineers will easily pass this year the 10,000 membership mark which was set last spring as a goal for 1919."

The Franklin Institute, acting through its Committee on Science and the Arts, has awarded its Edward Longstreth "Medal of Merit" to John Walter Ledoux, of Swarthmore, Pa., for the Simplex Venturi Meter, manufactured by the Simplex Valve and Meter Co., Philadelphia, Pa.

The Wallace & Tiernan Co., Inc., 349 Broadway, New York City, manufacturers of chlorinating apparatus for sterilization of water supplies and sewage, have recently made a change in their representative on the Pacific Coast. Their interests will hereafter be taken care of by Alexander Bell, with office at 709 Mechanics Institute Building, San Francisco, Cal. Mr. Bell will handle all installations on the Pacific Coast and will keep emergency outfits in stock.

H. W. Nelson's Plan of Payment for Estimating

Rules and Procedure Whereby Each Project is Considered Separately—Fundamentals to be Observed in Estimating—Statement Submitted by Mr. Nelson to Committee on Methods of the Associated General Contractors of America

ESTIMATING costs and establishing prices is an overhead expense involved in any merchandising, but the cost of doing so is generally nominal, if not insignificant, and can be justifiably distributed. The cost of figuring or estimating work to be peformed in accordance with special specifications to meet each case, however, differs materially from establishing a price on each of a thousand hats, all made from the same material and from the same pattern. The Nelson Form for Choosing Bidders and Awarding Contracts has, therefore, been suggested to meet special conditions; to more justly distribute the cost of competition and estimating, and to make each project bear its own proportion of the cost.

It is submitted with the thought that there are three main factors entering into the relations between the purchaser and the seller, viz.:—

1. Quantity and Quality of Materials.
2. Character of Labor and Personal Service.
3. Price to be Paid for Both.

The first factor can be determined and somewhat definitely set forth in the form of plans and specifications to be furnished by the purchaser to the seller, upon which the seller can base his price.

The character of the labor and personal service rendered by the seller or expected by the buyer varies as much as human nature varies, and cannot be so definitely or exactly set forth.

The price, or third factor, can be based definitely upon the materials, but must necessarily vary upon the Personal Service, depending upon the value placed upon it by either the seller or the buyer; therefore—

The purchaser should be allowed to exercise his recognized personal liberty in choosing the party with whom he wishes to enter into a contract, basing his choice upon price, his own confidence in the seller, his own judgment of the seller's qualifications or experience necessary to render the service he wants, or any other factor that he may himself consider most important.

And when the purchaser desires competition to enable him to make comparisons or decisions based upon a combination of all three factors, competition which involves labor and expense on the part of the seller, then the purchaser shall purchase that competition at a fair and just price, just as he purchases anything else.

Fundamentals in Awarding Contracts

Under the Nelson form of choosing bidders and awarding contracts, it is the intent:—

First—That the buyer may have just as much fair competition as he wishes to pay a reasonable and fair price for; that he, alone, desires the benefit of competition, and that no one buyer should pay for competition received by another —an abuse that exists under present methods.

Second—That when and after the buyer has chosen his competition in a fair, unprejudiced manner, and has further paid a just and reasonable price for said competition, he shall be under no moral or other obligation to the bidders; that he may make his own decision, based upon his own opinion of the qualifications of the bidder or the bidder's price, or a comparison of both.

Third—That the buyer may, as he chooses, select a limited or large number of bidders. If the work is of a private nature, he may wish to choose a very limited number, if he wants competition at all. If the work is of a public character, he may necessarily wish to give every qualified public citizen bidder an opportunity to compete, but without the necessity of paying more for the competition than he may consider the competition is worth.

Fourth—If the work be of a public nature, the buyer may have good reasons for first selecting a limited number of bidders because of their residence near the work to be done, or because they may be familiar with or may have had previous experience with the work, or for sundry justifiable reasons.

Fifth—That when the buyer, in case of public work, has then chosen his preferred bidders, he may give every other public citizen who is qualified to bid an opportunity to compete by chance or lot for consideration as a bidder, limiting the number to be chosen in accordance with the value of the competition to him.

Sixth—That the bidder shall in no way be considered as an engineer, but solely in the light of a bidder and contractor capable of doing work in accordance with complete plans and specifications; and that, therefore, in every case where bidders are expected to bid in competition, they (the bidders) shall be furnished by the buyer with plans, specifications, drawings and instructions covering the work to be performed as completely and specifically as commercially possible, with sufficient details to enable a bidder to fully understand what he is expected to figure and bid upon.

Seventh—That if a buyer cannot or will not provide complete detailed plans and specifications for the work, but wants estimates, measurements, figures or advice of a professional nature, then he (the buyer) shall consider such work in the light of a professional service, and it shall not be considered proper, fair or just to ask for competitive price bids, but that the charges for such professional service shall be left solely and strictly for adjustment between the buyer and seller, either before or after the work is done. Approximate estimates shall not be considered binding upon either party involved.

Reducing the "Gamble" to a Minimum

That under no circumstances shall the amount of a competitive bid be altered or the intent of the bid be changed so as to equivalently alter the amount after the bid has been submitted and before the contract has been let.

That no reductions or additions shall be made in bids for the purpose of meeting lower bids or because of proposed changes in plans and specifications. That under such proposals by the buyer, either new bids, based upon new plans and specifications, shall be asked and paid for—or—the contract shall be let and mutually satisfactory arrangements then made between the buyer and seller. That what is now known as "shopping" or "peddling" bids shall be discountenanced by both buyer and seller.

Such a system would place the expense of estimating where it belongs, i.e., as an expense against the job for which it is incurred. It would place the owner or architect under obligation to no one. He could, with fairness to all, let the contract to whomever he chose. The contractor could thus eliminate much more of the "gamble" in bidding, which would, in turn, benefit the material dealer and manufacturer, the bonding companies, and the bankers. The fact that owners and architects could choose their contractors as they saw fit without obligating themselves to choose the lowest bidder should not operate to increase graft or unfair discrimination. Crooked building committees or architects are the exception and very far from the rule, and there would not be any occasion for private owners to select contractors except on merit. Let the best man win, everything considered, not price only. At any rate, the possibilities for graft under such a system are not as great a menace to contracts as the evils of present-day competition and wasteful estimating.

Quantity Survey and the Nelson Form

The "Nelson Form of Choosing Bidders and Awarding Contracts" should not be construed as conflicting with the "Quantity System" or "Unit Systems." The Nelson Form

should be equally as just and fair if used in connection with the "Quantity System" as without.

The only way in which the "Quantity System" could affect the Nelson Form would be to reduce the bidder's compensation, because some of his work and service would be absorbed by the "Surveyor," and, of course, if the quantities are guaranteed by the surveyor, it would more materially reduce the bidder's compensation, if not eliminate it.

Many of the best, most successful and responsible contractors are opposed to "Quantity Systems" and "Unit Systems" for the reason that their universal and complete use would place the sale of building material in the hands of manufacturers and jobbers, and take it out of the contractor's hands altogether; and, therefore, the contractor under such

EXHIBIT A

Average of all bids or estimated net cost of contract	Approximate square root of figure in column one	Number of bidders to be selected† Figure in column two multiplied by .04	*Amount to be paid each bidder Figure in column two multiplied by .7	Total cost of competition Figure in column three multiplied by figure in column four
$ 50,000.00	224	9	$156.80	$1,411.20
60,000.00	245	10	171.50	1,715.00
70,000.00	265	11	185.50	2,040.50
80,000.00	283	11	198.10	2,179.10
90,000.00	300	12	210.00	2,520.00
100,000.00	316	13	221.20	2,875.60

Explanation

†Not less than two. As many more bidders may be selected as the buyer wishes to compensate.

To determine the total number of bidders, estimate the amount of the contract in dollars sufficiently high (Clause 3, Public Work); compute the square root and multiply by .04.

To determine the amount to be paid each bidder, add all bids (including any and all alternate figures asked for and received), divide the sum by the number of bids to get the average, then take the square root and multiply by .7. In case of fractions, the next highest whole unit number shall be used. Carefully read Clause 11, "Paying for the Competition."

*The multiplication factor .7 is not set or established. It is the intention of this form that this factor should be determined or established by the seller individually or collectively in the same manner in which he sets the price upon any merchandise or service.

Where it is necessary for the bidder to incur travelling or other incidental expenses it is the intent of this form that he shall receive remuneration for same in addition to regular compensation provided for in Exhibit A. The bidder shall, however, make arrangements with buyer for such special compensation, and have same accepted before bidding.

conditions would be reduced to a contractor of labor only, if, indeed, he could exist at all. And when it is understood that the handling of labor is generally fraught with more trouble and less profit than anything else in the contracting business, it can be readily understood that many of the good contractors say, that when that time comes, they will use their investments and ability in some other business.

Many architects are opposed to the "Quantity System" in this country at this time, because they think its use would delay the preparation of plans and specifications. They say that the American builder is inclined to wait until the very last minute before deciding to build; that he will plan and figure upon erecting his building for two years, then go to the architect and expect to move into it the next week.

The architect rarely has half enough time to do his work and do it as well as he wants to.

They say that if a quantity survey were to be made of each set of building plans and specifications, it must be nearly correct in every detail, and that the quantity estimator would require as much time as the architect to do his work right, and that altogether the time consumed between getting the commission for the architectural work and letting contracts would be two or three times as much time as the architect can get from his client.

And again it is contended that "Quantity Estimating" is essentially a new profession, and that it will be necessary to train men especially for that work; that while it may be possible to have the work done in the next few years in metropolitan cities, it will be many years before it can be accomplished in more sparsely populated centres.

The writer feels that from an ideal standpoint, "Quantity Survey" is something to be looked forward to with earnest eagerness, and is progressive enough to feel that there is great hope.

However, it will take time to bring it into practice, and when we have educated the public to appreciate that in the majority of times they get just what they pay for, and when we have converted the impulsive, impetuous, careless, "plan-nothing-ahead" present-day American builder into a safe, conservative, "plan-everything-ahead" builder, then we will have the more efficient, safe and sane method—"quantity system," and the quantity estimator will be here. Then, perhaps, the present-day American contracting gambler's successor will be the conservative quantity engineer. And that is all the subject really amounts to. Reduce the gamble and do more engineering. For "quantity estimating" is a professional engineering service.

In the meantime, during this generation, why not do everything we can to protect ourselves and the deserving present-day contractor from the unscrupulous ones by adopting a just method of competing which will not interfere with a higher and better class of engineering, such as the "quantity system" will give.

The Contractor Who Bids for Nothing

I am also frequently asked the question, "How are you going to prevent contractors from evading the practice if it is established?" By educating the contractor to better business methods, and by educating the architects and owners for their own good to refuse to consider contractors whose business methods are not correct. Those who can't be educated can do no good anyway. How could you prevent a man from giving his clothes away if he were foolish enough to do it? But when consumers and their representatives learn that they are really paying less for competition and getting a better class of competition one way than another, they will soon adopt the former. It was a long time before the "one-price-to-all" idea was adopted in selling merchandise. It came all at once and is now in almost universal use. Some merchants still dicker, but the better ones do not. Some contractors may bid without charging, but the better ones will not when they understand the advantages of this plan to them. Some contractors would also like to see their competitors charge for bidding so that they themselves can offer to bid and figure free of charge. But such men harm themselves mostly. At least, they or their practices are not the ones we should follow.

I believe the only solution of the problem is to have a national association of some kind, which is not organized for personal profit, take hold of it. They could inaugurate a system whereby the local organizations could, through their secretaries, put the system in force and collect compensation. The national organization in this way could collect from each local organization a small percentage of the compensation, and, I believe, thereby build up a very strong national organization financially, and in that way could keep the contractors together.

THE NELSON FORM

Rules and Methods of Procedure

PUBLIC WORK

1. Procuring Applicants to Bid Upon Public Work

If the work is of a public character, it is conceded that every public citizen who is qualified to bid shall be given consideration. Therefore, the buyer shall advertise in all recognized local newspapers simultaneously for a fifteen-day

period of time at least, setting forth that he intends to let a contract, requesting all those who wish to submit bids to file an application. Such advertisements shall clearly state the character of the work and its location. The application from bidder shall be in the hands of the buyer upon a certain date, and not less than fifteen days from the date the first advertisement appears. Immediately upon receipt of the application, the applicant shall be given a receipt therefor.

2. Approving the Applications from Bidders

Known incompetency, lack of experience in the class of work contemplated, insufficient organization, or insufficient capital or equivalent to carry out the contract, or unsatisfactory previous experience with applicant, shall all be considered good, just and sufficient reasons for non-consideration by the buyer and his refusal to approve the application. All other applications shall be approved and given consideration. It shall, however, be considered obligatory upon the buyer to immediately and fully state his reasons for failure to approve an applicant if called upon to do so.

3. The Number of Bidders to be Selected

The minimum total number of bidders to be selected shall be determined by taking the square root of the estimated net cost of the proposed contract in dollars and multiplying by .04 as shown (Exhibit A), or thus: If it is estimated that the contract cost will be $10,000, the square root of which is 100, multiply by .04, which gives 4 as the minimum number of bidders to be selected. In case of fractions, the number nearest the next highest whole unit shall be selected. It is obvious from the intent of this form that the buyer may have as many additional bids as he may want, provided he wishes to pay for the cost of such additional competition, and with the further provision that he fairly choose such additional bidders, as provided for in Clauses 4 and 5. Should it be found that the buyer, in case of public work, intentionally or unintentionally, has estimated the contract more than 10% lower than the lowest bid, it shall be considered good and just cause for complaint on the part of the uninvited public citizen bidders, on the grounds that the buyer has kept his estimate low so as to exclude bidders or reduce the number of bidders considered legitimate for public work under this form.

4. Preferred Bidders Selected by Buyer

The buyer may, at his discretion, or if he chooses for good and sufficient reasons to do so, select and invite one or more preferred bidders, but the number of such preferred bidders shall in no case exceed a number equal to one-half of the total number of all bidders selected. It shall, however, be obligatory in case of public work upon the buyer to immediately divulge or make public the names of such selected bidders, if requested to do so, and to give his reasons for selecting them.

Because a certain contractor is selected as a preferred bidder it shall not indicate that he is to be or shall be given preference in awarding the contract, but rather that the privilege given the buyer to select a limited number of bidders is more for the purpose of enabling him to obtain low but meritorious bids.

5. Bidders Chosen by Lot

The remaining number of bidders to be invited after the preferred ones have been chosen (Clause 4) shall be chosen by drawing lots thus: The names of all applicants (except those who may have been selected as per Clause 4) who have made written request upon regular form and have been approved by buyer as per Clause 2, shall be placed on stiff blank cardboards not smaller in size than one inch wide by three inches long. These cardboards, with the names of the applicants clearly written or printed upon them, shall be placed in any convenient opaque receptacle not less than five inches deep, closed on all sides and bottom, but open at the top. Then a totally disinterested or blindfolded party shall draw from said receptacle a number of cards, no more nor less than the number of bidders to be chosen by lot. The names of the applicants appearing upon the cards drawn shall be duly selected as bidders. This drawing shall be at all times open to the public or interested applicants.

6. Notifying Bidders and Bidders' Agreement

When the required total number of bidders have been chosen, all applicants shall be notified. The applicants who have been selected to bid shall then be given all necessary plans, specifications, drawings and instructions. They shall also be given a "Bidders' Agreement," which, after acknowledging receipt of plans, etc., binds the bidder to abide and conform to all rules and regulations set forth in "The Nelson Form for Choosing Bidders and Awarding Contracts," and the buyer to pay for the estimate the amount stipulated in the above-mentioned "Nelson Form," based upon the average of all bids within the stipulated time after letting contract.

These plans and the "Bidders' Agreement" may be handed to bidders in person or sent to them by United States registered mail, and no contracts shall be let or bids opened except as provided for under Clause 8 and Clause 9, until all invited applicants or their substitutes, as provided for under Clause 7, shall have returned signed "Bidders' Agreement."

7. Failure to Submit "Bidders' Agreement"

Should one or more bidders fail to return the "Bidders' Agreement" within fifteen days of registered mailing date of the notification, then the buyer may, if he so desires, choose other bidders to substitute for them under the same method described under Clauses 4 and 5, as the case may be, by or under the form by which the defaulting bidders were selected, and an extension of the time set for opening bids may be made.

8. Defaulting Bidders and Failure to Submit Bids

Failure on the part of one or more bidders (after they have submitted signed "Bidders' Agreement") to submit their bids in due time or in correct form shall not in any way obligate the buyer to defer or delay the awarding of the contract.

9. Failure to Secure Stipulated Number of Applications

Should the total number of applications from bidders after advertising the stipulated time not reach the number provided for in Clause 3 or Exhibit A, then the buyer shall reserve the right to open bids and let the contract with the number of bidders that have made application, without in any way violating any of the rules, terms, agreements or intentions of this form.

10. Awarding the Contract

If the buyer or buyers be acting in the capacity of public servants, or in behalf of organizations, they shall, in accordance with the intent and meaning of this form, award the contract on the basis only of serving the best interests of the public or their constituents, as the case may be. No personal prejudices shall be shown or personal preference given, but the award shall be based solely and only upon the basis of procuring the best material and service at the lowest cost. All bidders, however, to receive full compensation for estimating and furnishing competition, in accordance with Clause 11.

11. Paying for the Competition

After all bids have been received and opened, the buyer shall within ten days (whether or not contract has been awarded) pay to each and all bidders (who have bid in strict accordance and complied with all of the demands contained in the plans and specifications and all forms accompanying same, and whose bids do not exceed by more than 25% per cent. the amount of the bid upon which the contract is awarded, or the lowest legitimate bid if contract is not awarded) a sum equal to the square root of the average of all bids received multiplied by .7 substantially as shown in table (Exhibit A), thus: If the average of all bids received shall be $90,000, the square root of which is $300, multiply $300 by .7, which equals $210, the amount which shall be paid

to each competing bidder in payment for the labor and expense involved in estimating and as a complete waiver of all obligations. In considering the amount of each bid, the total bid, including the sums of all alternate estimates asked for by the buyer, whether they be additions or subtractions, shall be considered, and the amount to be paid the bidder shall be reckoned thereon as well as upon the total bid; as, for example, if the bidder is requested to estimate upon a brick building with alternate estimate upon stone and another alternate estimate upon frame construction, then, assuming that the bidder's figure is $20,000 upon the brick building, $30,000 upon the stone, and $15,000 upon the frame building, then the sum-total, or $65,000, shall be used in determining the sum to be paid the bidder. Should certain bidders refuse or neglect to figure or bid upon alternates, they shall be paid upon the basis of their actual bids only.

A certificate of payment shall, upon request, be given to each bidder, properly filled in, signed and sworn to by the buyer before a qualified notary public, setting forth that the competition has been conducted in accordance with this form, and that the amount credited or paid to the bidder has been reckoned and computed in strict accordance with this, the "Nelson Form of Choosing Bidders and Awarding Contracts," its true intent and meaning.

PRIVATE WORK

1. Selecting Bidders for Private Work

If the buyer of the work to be figured upon is acting as a private individual, then he may choose his own method for selecting bidders, and he may select as many or as few as he may choose or wishes to compensate.

2. Awarding the Contract

If the buyer be a private owner, he, his architect, his engineer or other form of representative shall reserve the right to make contract with any bidder he may choose, provided, however, that he shall fully compensate all invited bidders in accordance with Clause 3.

3. Paying for the Competition

Paying for the competition in connection with work of a private character shall be done exactly as provided for in connection with public work and as shown and set forth under Clause 11, Public Work.

The Sub-Contractor and the Material Man

In putting this plan into actual operation, the Quad City Builders' Exchange, including the Master Builders of Davenport, Iowa, Rock Island, Moline, and East Moline, Illinois, adopted the following regulations applying to subcontractors and material men:—

. . . . . .

Second.—That this body shall recommend the following minimum factors as a basis for compensating bidders in accordance with the Nelson Form:—

General Building Contractors.—.5 or 50% of the square root of the average of all bids.

Sub-Contractors and other Principal Contractors.—.2 or 20% of the square root of the average of all bids.

Third.—That the above factors shall be used when bids are given to owners, their representatives, or to other contractors when such other contractors are not in competition.

Fourth.—When one contractor, however, renders a bid to another contractor who is in competition, it is arbitrarily assumed that the contractor giving the bid will, on the average, give four bids on the same work which he will have to figure or estimate only once. Therefore, under such subbidding conditions (and only under such conditions), the compensation shall be one-fourth of the regular compensation, or as follows:—

General Building Contractors.—.125 or 12½% of the square root of the average of all bids.

Sub-Contractors. and other Principal Contractors.—.05 or 5% of the square root of the average of all bids.

Fifth.—Building material manufacturers or distributors shall not receive compensation for making unit prices on material. For example, if a price is quoted upon 10,000 brick at $9 per thousand, or 5,000 yards of sand at 60 cents per yard, etc., such bidding shall not deserve compensation; but if such bidder is expected to estimate the material required to do the work intended and then guarantee the quantities or capacities to be sufficient, then he shall be considered in the light of a contractor and receive compensation.

Sixth.—That when the owner, or his representative, furnishes the bidder with guaranteed "quantity surveys"—or, in other words, with a unit of material upon which the bidder needs only insert unit prices and is relieved of the necessity of guaranteeing the quantities to be correct—then the amount of such unit list or quantity survey shall be deducted from the amount upon which the bidder is compensated.

BRITISH COLUMBIA TECHNICAL ASSOCIATION

THE British Columbia Technical Association held its first banquet on October 21st, in the University Club, Vancouver. The gathering took the place of the regular monthly meeting of the association at which it has been customary to deal with purely business matters. The executive intend hereafter to combine every business meeting with a social function. About one hundred civil, electrical, mechanical and mining engineers, chemists and architects were present. The chair was occupied by E. G. Matheson, professor of civil engineering of the University of British Columbia, who gave an interesting address, in the course of which he outlined the great part in the world's work which had fallen to the lot of technically trained men. He reviewed the activities of the association and stated that while the organization is only about eight months old, the membership is about 250, and that a total of 300 is expected by the end of the year. The secretary-treasurer of the association is R. Snodgrass, Board of Trade Building, Vancouver.

EFFECT OF FINENESS OF CEMENT

(Continued from page 438)

15.—Concrete of all mixes and consistencies showed expansion in damp sand or water storage and contraction in air.

16.—The change in length of concrete specimens stored in air or water is independent of the fineness of the cement and the consistency of the concrete. The lean concretes are slightly less affected than the rich mixtures.

17.—The type of aggregate had little or no influence on the relative effect of fineness of cement on the strength of concrete.

18.—The tests included showed an intimate relation between the strength of the concrete and the water-ratio of the mixture. The lower the water-ratio (so long as the concrete is plastic and the aggregate not too coarse), the higher the strength, and vice versa. This confirms the results of other concrete tests made in this laboratory. Increasing the quantity of cement in a given mixture enables us to secure a concrete of equal workability with a lower water-ratio, hence a higher strength.

19.—In ordinary concrete mixtures (say 1:5 to 1:4, requiring 20 to 25% cement, by volume) increasing the cement content by 1% (to 20.2% for a 1:5 mix), gives an increase in strength of about 1%.

20.—One per cent. increase in cement is more effective in increasing the strength of concrete in lean than in rich mixtures.

21.—One per cent. increase in cement is somewhat more effective in increasing the early strength of concrete than at later periods.

22.—The effect of increasing the quantity of cement is independent of the consistency of the concrete.

23.—Tension tests of briquets do not give a correct measure of the relative merits of different cements as determined by compression tests of mortar and concrete.

WATER PRESSURE UNDER DAMS

IN an article upon another page of this issue, Mr. Maerker calls attention to what he terms a "fallacy in the design of dams subject to upward water pressure." He points out that the overturning moment due to the upward thrust of water near the heel of a dam should not be added to the overturning moment due to the horizontal water pressure unless the upward thrust is greater than foundation reaction. He bases his argument on the fact that the upward thrust due to water simply replaces an equal amount of foundation reaction. He admits, however, that the stability of the dam is impaired by the upward thrust of water, owing to the lowering of the resistance against sliding. Allowance would have to be made, therefore, when designing the structure, for this danger of failure through sliding.

Whether the allowance be regarded as a provision against overturning or against sliding, probably makes but little practical difference. In either case basic assumptions must be taken that may vary greatly in their actual accuracy, and the results might not be such as to warrant the refinement suggested by Mr. Maerker.

Nevertheless it is always interesting to discuss the reasons for assumptions, as it leads to a clearer understanding of the various features of design. Engineering should be based upon scientific laws to as great an extent as possible. It should be empirical only where absolutely necessary through lack of accurate knowledge, or else where advisable in order to save mathematical computations which, if carried out, would yield no adequate return.

While Mr. Maerker's article may not change any of the assumptions used in designing dams and similar structures, it will cause many engineers to give further thought to the subject, which alone will prove beneficial regardless of whether these engineers do or do not find themselves in agreement with the theories advocated by Mr. Maerker.

. The amount of the upward thrust, the area against which it acts, and the line of its distribution, must all be assumed, and in order to be reasonably safe the engineer must make considerable allowance for more than average conditions. The precautions taken by standard engineering practice in the past have no doubt been warranted, and Mr. Maerker would probably insist upon just as much material being used in a dam designed according to the method he suggests, as in a dam designed in accordance with present standard practice.

ENGINEERS FAVOR EMPLOYMENT ACTIVITIES

RESULTS of a referendum recently held by the American Association of Engineers, asking the opinion of the membership as to how the income of the association should be distributed amongst the ten main activities of the association, indicate that of all the things which the members believe to be important, the employment service is the most popular.

The vote proves that the members desire to have about 17% of the income spent on this service. It is interesting to note that compensation was second with about 16%. The official publication, promotional work, publicity, legislation, protection and prevention of abuses, membership, civic welfare, and ethics and practice, were next, in the order named.

Mining engineers voted the greatest percentage to employment, while the least percentage voted to employment was by those engineers employed by educational institutions. Government engineers voted more to be spent on publicity than did any other class of members. The greatest desire for development of the organization appears to lie in the educational group, for those engineers voted 3% more for promotional work than did any other class of engineers.

Public utility employees voted the greatest amount to be spent on legislation, although engineers employed by states ran a close second. Legislation was least desired by government engineers, who voted a full 3% less than those employed by public utilities.

Engineers in private practice voted the greatest amount to be spent on civic welfare work. The least amount voted to this work was about 3%, voted by mining engineers. Engineers in private practice voted a greater amount to be spent on protection and prevention of abuses than did any other class of members.

Municipal engineers voted the most money to be spent on compensation, while railroad engineers, engineers in public utility work, and engineers employed by states, followed in the order named. The complete results of the ballot follow:—

Employment, 17.4%; compensation, 16.3%; association's publication, 14.8%; promotional work, 10.9%; publicity, 9.8%; legislation, 8.8%; protection and prevention of abuses, 8.1%; membership campaign, 5.8%; civic welfare, 4.5%; ethics and practice, 3.6%. The percentage named in every case is the average of the votes cast by the members, and therefore represents the average opinion of the membership as to the percentage of the association's income that should be spent for the various activities.

The result of the vote, as regards employment activities, is no surprise. Just as self-preservation is the first law of nature, the first and basic desire of all engineers—and of everyone else for that matter—is to be ensured of a good market for their abilities. Ethics, membership campaigns, etc., are naturally regarded as of minor importance compared with employment. At the same time, legislation, publicity and other activities have a basic effect upon employment, and in the last analysis may count for more than the direct assistance rendered by a society's employment bureau.

The obligation upon every individual to purchase Victory Loan bonds may not be so apparent as it was during the war, but it is just as real. Depression and unemployment would surely follow the country's failure to absorb the much-needed loan.

PERSONALS

THOMAS R. LOUDON, who was recently relieved of his military duties after having been in the army since November, 1915, has returned to private practice in Toronto and, in partnership with C. S. L. Hertzberg, has formed a new firm, Loudon & Hertzberg, consulting industrial and structural engineers. Mr. Loudon was born September 1st, 1883, in Toronto and was educated in the public schools in that city and at the University of Toronto, where he graduated in 1905, with the B. A.Sc. degree in civil engineering. For one year after graduation Mr. Loudon was engaged in design of gas engines for the McVicker Engine Company, of Galt, Ont. In 1907, he was appointed lecturer in civil engineering at the University of Toronto, and has retained his connection with the university since that date. In 1912, he was appointed assistant professor of applied mechanics, and while he was in the army he was gazetted by the faculty as an associate professor. He has resumed his lectures at the university. Mr. Loudon is the author of "Applied Statics," which he originally wrote as a series of articles for *The Canadian Engineer*, and which has since been used as a text-book by the University of Toronto and other educational institutions. Before the war he was a frequent contributor to *The Canadian Engineer*, and for a time acted as an associate editor of the paper in regard to structural steel and its production. From the beginning of his connection with the university, Mr. Loudon has at all times been in touch with outside work. From 1907 to 1912 he assisted the late T. C. Irving in the inspection of structural steel work for the Standard Inspection Co., of which Mr. Irving was manager, and later for the Robert W. Hunt Co., which absorbed the Standard Inspection Co. and of which Mr. Irving became vice-president. Mr. Loudon also acted as consulting metallurgical engineer for a number of enterprises, chief of which was the Moffatt-Irving Co., Toronto, for whom he acted as consulting and designing engineer, in association with J. W. Moffatt, from 1910 to 1912. This company was organized for the purpose of making experiments in the electrical smelting of iron ore. In 1912 Mr. Loudon became a member of the firm of James, Loudon & Hertzberg, consulting engineers, Toronto, and for the following three years was engaged in various structural and municipal undertakings. In November, 1915, he enlisted as lieutenant in the 2nd Field Company, Canadian Engineers, and was appointed on the staff of Military District No. 2 as an engineering instructor. In May, 1916, he was gazetted captain and adjutant of the 1st Construction Battalion, and went to France with that unit, arriving at the front in October, 1916. He attained his majority on the field before the end of that year, and served as second in command of his battalion until he was invalided home in May, 1918. In 1917 that battalion became the 1st Railway Troops. It was engaged in general engineering construction, chiefly bridges and standard-gauge and light railway work. Major Loudon was mentioned in dispatches for his work at the front. In October, 1918, after he had recovered from his injuries, he was apointed in command of military engineering construction in British Columbia, from which position he was honorably discharged in June of this year.

HADDIN & MILES, LTD., consulting engineers, have moved their head office from Winnipeg to 209 Eighth Ave. W., Calgary, Atla.

MAJ. P. EARNSHAW, of Toronto, has been appointed instructor in civil engineering at the Royal Military College, Kingston, Ont.

F. P. JONES, vice-president and general manager of the Canada Cement Co., Ltd., has resigned from the directorate of the Canadian National Railways owing to pressure of other work.

J. L. ENGLEHART, chairman of the Temiskiming & Northern Ontario Railway Commission, has resigned owing to ill-health. Mr. Englehart has been chairman of the commission since its formation, 14 years ago.

J. C. REILLY, acting general secretary of the Association of Canadian Building and Construction Industries, left Montreal last week for a four weeks' tour of Western Canada. Mr. Reilly will hold organization meetings in Winnipeg, Regina, Calgary and Vancouver. He may also visit Saskatoon and Edmonton.

J. A. ELLIS, Director of Municipal Affairs of Ontario; LAWRENCE VEILLER, secretary of the National Housing Association, New York City; and W. J. DONALD, secretary of the Board of Commerce, Niagara Falls, N.Y., will be among the speakers at the town planning convention to be held November 27th and 28th in Hamilton, Ont.

ENGINEERING INSTITUTE ELECTIONS

AT a meeting of the council of the Engineering Institute of Canada held October 28th, 1919, in Montreal, the following elections and transfers were announced:—

Members.—F. L. Butler, Winnipeg; W. L. Ketchen, Timiskaming; R. L. Peek, St. Catharines; A. H. White, Brooklyn, N.Y.

Associate Members.—A. N. Ball, Regina; F. M. Barnes, St. John, N.B.; H. F. G. Barnjum, Prince Rupert, B.C.; E. H. Beck, Toronto; Sydney Bowen, Morrisburg; L. L. Brown, Vancouver; A. W. L. Butler, St. Catharines; Neil Campbell, Ottawa; E. D. W. Courtice, Chatham; H. R. Cram, Ottawa; F. A. Danks, Toronto; H. W. L. Doane, Halifax; J. G. Dryden, Halifax; R. L. Fairbanks, Port Arthur; K. C. Fellowes, Niagara Falls; A. G. Graham, Vancouver; Byron Hallock, Winnipeg; S. W. Johnston, Niagara Falls; Grover Keith, St. John, N.B.; R. F. Macdonald, Sault Ste. Marie; R. H. Mather, Montreal; H. W. McKiel, Sackville; J. W. McLellan, New Glasgow; D. A. S. Mutch, St. Catharines; W. F. Oldham, Winnipeg; E. R. Pease, Montreal; W. H. Stuart, Hanna, Alta.; H. S. Tawse, Aberdeen, Scotland; W. C. Taylor, Stonewall; A. R. Whitelaw, Campbellford; J. R. Wood, Evesham; E. M. Wynn, Niagara Falls; A. G. Young, Toronto.

Juniors.—E. W. G. Chapman, Halifax; L. H. Cookson, Bathurst; K. L. Dawson, Halifax; W. S. McDonald, Calgary; J. M. Poole, Halifax; E. G. Timbrell, Ottawa.

Transferred, associate members to members.—Charles Brakenridge, Vancouver; P. P. Brown, Vancouver; J. C. Craig, Vancouver; W. A. E. Grim, Vancouver; J. C. Holden, Winnipeg; W. H. Magwood, Cornwall; D. M. Mathieson, Toronto; R. G. Saunders, Toronto.

Transferred, juniors to associate members.—R. S. C. Bothwell, Toronto; Arthur Desrosiers, Detroit; A. D. Kerrisdale, B.C.; J. M. Gordon, Toronto; C. E. Hogarth, St. Catharines; F. C. Knight, Montreal; L. P. Macrae, Victoria; W. P. Murray, Lachine; J. B. O. St. Laurent, Ottawa; R. A. Spencer, Montreal; C. St. J. Wilson, Halifax.

Transferred, students to associate members.—R. M. Calvin, Ottawa; W. E. P. Duncan, Milton; R. R. Hepinstall, New Orleans, La.; A. A. Richardson, Peterborough.

Transferred, students to juniors.—G. F. Alberga, Montreal; J. F. Brett, Montreal; W. McG. Gardner, Montreal; B. A. Johnston, Winnipeg; G. W. F. Johnston, Ottawa; G. F. Layne, Cheshire, England; W. G. Mawhinney, Selkirk; D E. McPherson, Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

ADDITIONAL TENDERS PENDING

Not Including Those Reported in This Issue

BRIDGES, ROADS AND STREETS

Belleville, Ont.—City council is considering the construction of a granolithic walk near Grove St., the paving of Murney Hill and a portion of West Bridge St. City engineer, S. G. Mill.

Boston Creek, Ont.—According to a statement made by Geo. J. Miller, president of the Miller Independence Mine, the company has decided to construct a first-class road from Boston Creek Station to the mine, for which the contract has already been let. A 16-ft. bridge will also be built.

Calgary, Alta.—The Utilities Board, Edmonton, has approved of the construction of the new Louise bridge over the Bow River at Hillhurst. City engineer, G. Craig.

Dryden, Ont.—On November 6th a conference will be held here to discuss the building of a highway from the head of the Great Lakes to Winnipeg. It will be attended by representatives of the various municipalities interested, including Winnipeg, Fort William and Port Arthur.

Glace Bay, N.S.—A new steel bridge will be erected here. Town engineer, A. McKinnon.

Goderich, Ont.—The town council is considering the widening of South St., between Britannia Rd. and Blake St. Clerk, L. L. Knox.

Golden, B.C.—Tenders will be received by the Honorable the Minister of Public Works, Victoria, B.C., up to noon, November 12th, 1919, for the erection and completion of a highway bridge over the Kicking Horse River at Golden, B.C. Plans and specifications may be seen at the department of public works, parliament buildings, Victoria, B.C.; the office of the district engineer, court house, Vancouver, B.C., and at the office of the assistant district engineer at Golden, B.C.

Hamilton, Ont.—City council intends to undertake the grading of several roads at a cost of $17,481.75. City clerk, S. H. Kent.

Kingston, Ont.—City council passed a by-law for concrete walks on Collingwood and Couper Sts. City engineer, R. J. McClelland.

Laterriere, Que.—A 70-ft. span bridge, with concrete abutments, is being built by the municipality. Tenders will be called for steel superstructure. Engineer, J. F. Tenon, Chicoutimi, Que.

London, Ont.—Forty-seven and one-tenth miles of the streets were oiled this year at a cost of approximately $25,000. This shows an increase of three miles over last year's oiling record, which was 44 miles.

Manitoba, Province of.—At the December elections by-laws will be submitted to the ratepayers of the municipalities of St. Andrews, Brokenhead, Springfield, St. Clements and East St. Paul, authorizing the borrowing on debentures of $552,000 for the construction of 303 miles of gravelled highways at a total cost of $1,152,677.

Oakville, Ont.—The erection of a high-level bridge to replace Aberdeen bridge is being considered by the town council. Mayor, Mr. Davis.

Ottawa, Ont.—The Carleton county council held a special meeting on November 5th to pass a money by-law for the purpose of erecting a bridge on Concession 4, Fitzroy township. County road superintendent, Samuel McClure, Galetta, Ont.

St. John, N.B.—Commissioner Fisher submitted to the city council a programme of street paving for 1920 involving an expenditure of about a million dollars.

St. Louis de Gonzague, Que.—Contract let to Payant and Micheux by the municipality for the construction of a macadam road, estimated to cost $38,000.

Three Rivers, Que.—Tenders will shortly be called for the construction of a road, estimated to cost $12,000. Engineer, Z. Lambert.

Toronto, Ont.—Works Commissioner R. C. Harris has been instructed by the Board of Control to proceed at once with the construction of a new pavement on St. Clair Ave., from the end of the present pavement to Keele St.

Toronto, Ont.—Commissioner of Works R. C. Harris has recommended the extension of Sellers Ave. southerly to Goodwood Ave. at a cost of $6,250.

Toronto, Ont.—The erection by the C.P.R. of a new bridge over the tracks at Main St., East Toronto, is being considered by the Dominion Railway Board; also the construction of a subway at the crossing over the Grand Trunk and the Canadian Pacific tracks at Royce Ave.

Toronto, Ont.—The works committee has approved of the construction of an asphalt pavement on Gerrard St., from Main St. to the east city limit. The probable cost is $182,441. The committee also sanctioned a 24-ft. asphalt pavement on 5-in. concrete foundation on Swanwick Ave., from Main St. to Pickering St., at a cost of $36,720.

Toronto, Ont.—The following contracts have been let for the construction of pavements, sidewalks and curbing: Alvin St., $4,991, Don Crest Rd., $7,761, Weston Rd., $3,481, to Commissioner of Works, City Hall; St. Clarens Ave., $63,451, Weston Rd., $10,822, Constructing and Paving Co., Confederation Life Building; St. Clair Ave., $28,142, Weston Rd., $19,624, Godson Contracting Co., Manning Chambers; Caledonia Rd., $23,578, Warren Bituminous Paving Co. of Ontario, McKinnon Building; St. Clair, $8,873, Grant Contracting Co., 50 Front St. East; concrete sidewalk on Mount Pleasant Rd., $2.23 per sq. yd., Commissioner of Works; concrete curbing on Alvin, Don Crest, Weston Rd. at 75 cents per lineal foot, Godson Contracting Co., Manning Chambers.

Victoria, B.C.—Contract for the construction and erection of a steel viaduct over Deep Creek, on the P.G.E. Ry., seventeen miles north of Williams Lake, has been let by the government to the Canadian Bridge Co., of Walkerville, Ont., at $330,000, this bid being the lowest of four received. The highest bid was $401,000. The viaduct will have a span of

1,160 ft. from abutment to abutment, and will be 300 ft. in height. Some four million pounds of steel will be required.

Victoria, B.C.—City Engineer F. M. Preston has been instructed by the city council to prepare an estimate of the cost of extending and opening up Lang St.

Winnipeg, Man.—City council intends to construct an asphalt pavement on Logan Ave., from East St. to the west side of Blake St. Estimated cost, $9,489. City clerk, C. J. Brown.

Winnipeg, Man.—Sitting as a special sub-committee of the works committee recently, Aldermen Pulford and Fisher heard a deputation urging the city to lend its support to the proposed Vimy highway. It was decided to recommend the works committee to favor the proposed highway across the city, provided no financial obligations for the city are involved. Messrs. Stuart, Atcheson and Kelly composed the delegation.

York Tp., Ont.—A number of street improvements have been authorized by the township council, including the widening of Atlas Ave. Engineer, Frank Barber, 40 Jarvis St., Toronto.

York Tp., Ont.—Township council accepted the tender of the Asphaltic Concrete Co. for the laying of a 24-ft. Tarvia pavement on Millerson Ave., from Glenholme Ave. to Lauder Ave., a distance of 240 ft.

WATER, SEWAGE AND REFUSE

Acton, Ont.—The electors on October 31st carried the waterworks by-law for $80,000. The plant will include deep wells, pumps, pump-house and about four miles of main. The E. A. James Co., Ltd., 36 Toronto St., Toronto, are the engineers. The work will commence at once.

Belleville, Ont.—City council let contract to Wilde and Bumbaca for the construction of sanitary sewers on Queen, Everett, Henry and Cedar Sts. at $9,297.89, and to Wm. Donohue for the construction of sanitary sewers on West Moira, North Front and Grove Sts. for $15,266.19.

Blenheim Tp., Ont.—Tenders will be received by Hugh Allan, township clerk, Drumbo, Ont., up till noon on Saturday, November 8th, for the furnishing of 287 ft. of 4-in. tile, 555 ft. of 5-in., 1,175 ft. of 6-in. and 1,064 ft. of 8-in. tile, delivered at Richwood Station; also for the performance of the work required in the construction of the Burns drain, in the township of Blenheim. Plans and specifications may be seen at the clerk's office in Drumbo.

Drumheller, Alta.—Municipality plans water main extensions at an estimated cost of $5,000. Clerk, H. A. Brown.

Kingston, Ont.—City council passed a by-law for the construction of a sewer on Russell St. City engineer, R. J. McClelland.

Kitchener, Ont.—Kitchener and district are interested in the fact that among the recommendations by the Soldiers' Re-establishment Commission is a clause urging an investigation of the irrigation small land holding scheme suggested by N. Cauchon, engineering expert, of Ottawa, who recommends the Hamilton district. The plan would necessitate a conservation of the waters of the Grand River and the building of big dams in the territory north of the city. The idea originated with a local civil engineer, W. S. Breithaupt.

Lindsay, Ont.—Council will proceed with the construction of a storm sewer on Victoria Ave. Town engineer, Oliver Smith.

Owen Sound, Ont.—The Public Utilities Commission has requested the town council to pass a by-law authorizing the issue of $10,000 worth of debentures for the construction of a filter bed and other extensions. City clerk, Chas. Gordon.

Peterboro, Ont.—City council decided to install a sewer on Park St., from Cedar St. to the creek south of McDonnel St. City engineer, R. H. Parsons.

Saskatoon, Sask.—City council decided to have the ratepayers vote at the December elections on the question of a suitable site for the proposed incinerator. Pending their decision, action on the plans will be deferred. In the meantime, the city council is looking into a proposition, submitted by Dr. J. A. Armstrong, of the Saskatchewan Oakoal Co., Ltd., to press all the garbage into briquettes to be used as a substitute for coal. Dr. Armstrong stated that all the city was required to supply was a skeleton building and the garbage and the company would do the rest, installing a $40,000 plant.

Scarboro' Tp., Ont.—The council have instructed the E. A. James Co., Ltd., 36 Toronto St., Toronto, to proceed at once with detailed plans and specifications for an intake, pump-house and filter-house with a capacity of 2,000,000 gallons. The plant will be situated south of Birch Cliff, and will serve that part of Scarboro' west of the Kennedy Rd. and south of St. Clair. Such work as can be done during the winter will be started at once. The installation will cost some $300,000.

St. John, N.B.—City council may have a water main laid to Spruce Lake. City engineer, G. N. Hatfield.

St. Vital, Man.—The rural municipal council intends to sink a public well on the north side of Sadler Avenue. E. A. Poulain, secretary-treasurer.

Timmins, Ont.—Work on the installation of the new sewage and water systems is being pushed forward with all possible haste. In all, 23,000 ft. of sewer line, ranging from 8-inch to 18-inch, has been planned, including 6,400 ft. of trunk line, extending from the boundary down to where the disposal plant will eventually be located, some distance past the junction of the Mountjoy and Mattagami river. The remaining 16,600 ft. will serve all residences in the town. To date, there remains about 5,000 ft. of sewer line to be completed. The original plans for the construction of the sewage disposal plant are to be revised shortly, and work will likely be commenced next spring. The plans for the water pipe line call for approximately 9,600 ft. Of this, 4,500 ft. have yet to be completed. The engineering work is in the hands of Sutcliffe and Neelands.

Vancouver, B.C.—The Board of Works has approved of the following sewer extensions: City's main sewer, from St. George to Carolina Sts., and thence to the lane east, estimated cost, $4,430; two blocks, between Burns and St. Catherines St., $3,576, and a half block on Fourteenth Ave., between Cedar and Pine Sts., $500. City engineer, F. L. Fellowes.

Walkerville, Ont—The Walkerville Water Co., Ltd., have awarded contract to the Turbine Equipment Co., Ltd., Toronto, for a 450 h.p. De Laval steam turbine-driven geared pump, with a capacity of 5 M.G.D.; domestic head, 165 ft.; fire head, 315 ft.

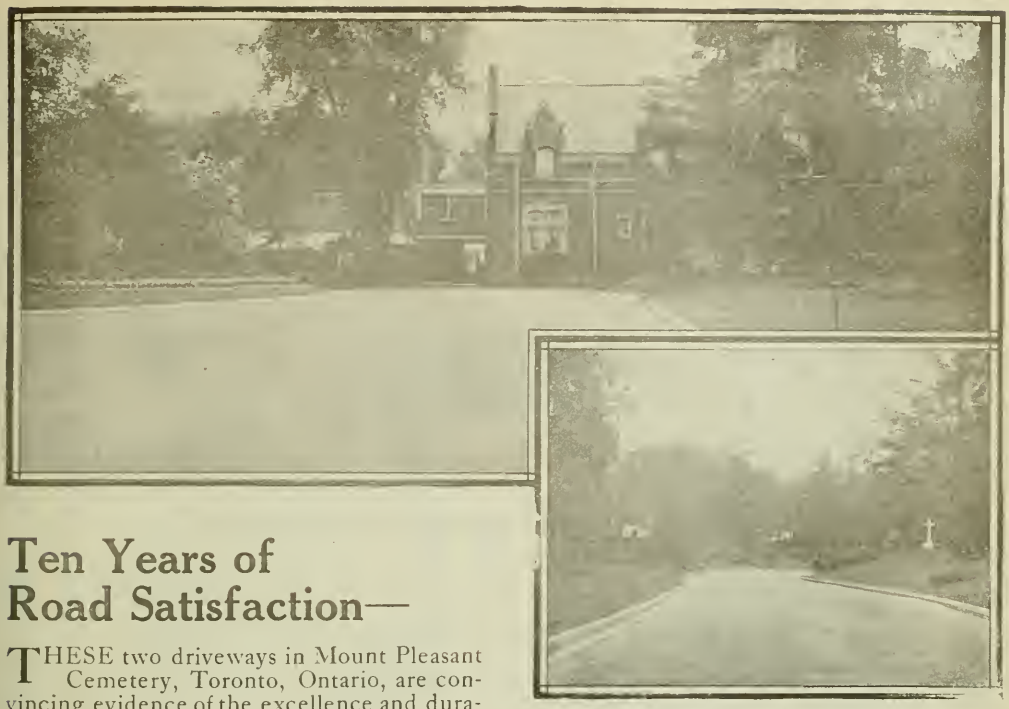
Winnipeg, Man.—Contract let by the city council to the Dominion Construction Co. for a water main on Myrtle St.

Winnipeg, Man.—City council intends to construct a sewer in Pritchard Ave., from Prince St. eastward to the C.P.R. Selkirk branch. Estimated cost, $1,350. City clerk, C. J. Brown.

Winnipeg, Man.—At a recent meeting of the water board, it was agreed that immediate steps should be taken to under-drain the Greater Winnipeg water aqueduct. The cost will be from $400,000 to $750,000. It was decided to have the five consulting engineers who have made reports on the necessity of the work attend the next meeting of the board. W. G. Chace, chief engineer, urged that tenders be called for now, so that an early start could be made in the spring. The board decided not to build a 250,000,000-gallon reservoir at Deacon.

York Tp., Ont.—The township council passed a by-law whereby the funds necessary to go ahead with the waterworks construction programme will be temporarily advanced by the Canadian Bank of Commerce.

York Tp., Ont.—Township council adopted the report of F. Barber, township engineer, on a number of water mains, and also instructed the waterworks superintendent to call for tenders for the purchase of 500 service meters.



Driveways of old macadam in Mount Pleasant Cemetery, Toronto, Ont., resurfaced with "Tarvia-X".

Ten Years of Road Satisfaction—

THESE two driveways in Mount Pleasant Cemetery, Toronto, Ontario, are convincing evidence of the excellence and durability of Tarvia as a road-making and preserving material.

The lower of these two roads was given a 3-inch resurfacing with "Tarvia-X" in 1909. The upper road was resurfaced in the same way in 1910. The above photographs were taken in 1918. The condition of these driveways today after many years of service, speaks for itself.

Tarvia Helps Canadian Road Engineers

Canadian road engineers have severe conditions to face. Canadian roads must not only be strong enough to stand up under the wear of traffic, but they must also be waterproof and frost-proof or they will not come through the severe winters and the spring thaws without going to pieces.

At the same time the expense of the roads must not be out of proportion to adjoining property values.

No material meets all these conditions so satisfactorily as Tarvia. It is a coal-tar preparation made in several grades, suitable for new road construction, reconstruction, surface treating or patching.

Tarvia is easily applied; it prevents dust and mud; it stands up well under motor traffic; and its cost is low.

Booklets free on request.

Tarvia

Preserves Roads-Prevents Dust

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by anyone interested.

If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention.

MONTREAL TORONTO
WINNIPEG VANCOUVER

The Barrett Company LIMITED

ST. JOHN, N.B. HALIFAX, N.S.
SYDNEY, N.S.

Woodstock, Ont.—Ald. Parker, chairman of the special sewer committee, reported to the city council that the cost of the proposed new intercepting sewer is estimated at $41,-312, and of the sewage disposal plant at $51,983. Council decided to submit the report to the Provincial Board of Health for approval, and to have a by-law prepared to submit to the electors as soon as the Board's approval is secured.

York Tp., Ont.—The township council gave the first reading to a by-law to authorize F. Barber, township engineer, to take preliminary proceedings to install a water main and service pipe on Montye Ave., from Willard Ave. easterly to Jane St., and on Windermere Ave., from Morningside Ave. southerly.

LIGHT, HEAT AND POWER

Calgary, Alta.—The extension of telephone lines in this city and the erection of new buildings and sub-exchanges is planned by the Provincial Government Telephone Department. Deputy Minister of Railways and Telephones, Norman Harvey, Edmonton.

Edmonton, Alta.—The Utilities Committee may find it necessary in the near future to purchase new machinery for the power plant. Chairman, Ald. J. A. Kinney.

Montreal, Que.—Tenders for briquetting machinery will be received by the Lignite Utilization Board of Canada at its office, 80 St. François Xavier St., Montreal, until 12 o'clock noon, December 14th, 1919. Specifications may be obtained from Lesslie R. Thomson, secretary of the Lignite Utilization Board.

New Liskeard, Ont.—Sutcliffe and Neelands, of New Liskeard, and McCarthy and Porter, of Elk Lake, are looking into the question of developing Hydro-electric power at the Indian chute on the Montreal River, about 12 miles above Elk Lake, to supply the surrounding mining district. It is considered that 5,000 h.p. can be made available at this point. It is also stated that private enterprise will provide a railway. In fact, it is believed that the contract has been already signed, and that work will begin in the spring.

Regina, Sask.—A representative meeting of ratepayers passed a resolution, practically unanimously endorsing the natural gas franchise by-law. Commissioner Thornton estimates the cost of the pipe line, assuming the length to be 200 miles, at $5,000,000.

Waterloo, Ont.—Manager Schiedel, of the Waterloo Water and Light Commission, has notified the Hydro-Electric Power Commission to have plans and specifications prepared for the proposed addition to the power house here, after which tenders will be called for.

RAILWAYS

London, Ont.—A by-law to authorize the purchase of the Street Railway by the city will be submitted to the ratepayers at the next municipal election, providing the city council adopts the suggestion of Mayor C. R. Somerville.

Montreal, Que.—City commissioners will insist on the Tramways Commission ordering the Tramways Co. to construct a stub line from Atlantic Ave. along Beaumont St. and up Bremner St., construction to commence next spring.

St. Catharines, Ont.—In a conference with the civic authorities, D. B. Hanna, of the Canadian National Railways, has offered, in return for the extension to 1937 of the franchise of the electric lines in this city and district, now under control of the government, to build a $50,000 station, extend city lines and shorten the route to Welland.

Windsor, Ont.—The plans of the Hydro-Electric Power Commission of Ontario to purchase the Sandwich, Windsor and Amherstburg Ry. for $2,100,000 were unanimously approved by the border municipalities.

FACTORIES AND LARGE BUILDINGS

Baintree, Alta.—Tenders will be received by the Board of Trustees of Baintree School District, No. 3804, at the office of H. Kruse, Edmonton, secretary-treasurer, up to noon, November 18th, 1919, for the erection of a frame school building. Plans and specifications may be seen at the offices of the secretary-treasurer, Baintree; J. A. McGregor, 3735 7th St. West, Calgary, and the Department of Education, Edmonton.

Belleville, Ont.—The Chemical Products Corporation, Ltd., Toronto, propose to spend about a million dollars on the construction of a plant here.

Brantford, Ont.—A permit for the erection of a factory for Robbins and Meyers, in the Holmedale district, Brantford, has been applied for. The cost of the new building is estimated at $150,000, and the dimensions are 80 ft. by 411 ft.

Bridgeburg, Ont.—The Brazil Motors Co., of Brazil, Indiana, a $2,000,000 industry, is looking for a site for the establishment of a Canadian plant. Both Bridgeburg and Welland are being considered.

Brockville, Ont.—Returned soldiers of Brockville and points in Leeds and Grenville counties at a meeting held here urged the erection of a Great War Veterans' clubhouse as a permanent war memorial for these counties.

Calgary, Alta.—A permit has been issued to Lougheed and Taylor for the erection of a garage on Ninth Ave., between First and Second St. West at a cost of $30,000.

Calgary, Alta.—By-laws to authorize the following expenditures are being prepared and will shortly be submitted to the city council for approval: Children's shelter, $60,000; waterworks extension, $207,345; sewage disposal plant, $350,000; hospital extension, $120,000.

Edmonton, Alta.—Tenders on the general construction, plumbing and heating and electrical work for the new telephone building were recently opened by the City Commissioners. In all cases they were referred to the city architect for tabulation and report. The lowest bid on the general building work was $78,753, submitted by the E. N. Nesbitt Co. Other tenders were: J. Dunlop, $82,105; H. G. McDonald, $82,222; Speers and MacAfee, $106,570. Tenders submitted for the plumbing and heating work were as follows: Lockerbie and Hole, $12,723; S. L. Dobbin and Co., $12,910; Kelly and Kokott, $13,277; Standard Heating and Plumbing Co., $13,109; Ross Brothers, $13,859; McKnight and Frost, $14,419; Ideal Heating and Plumbing Co., $15,-221. On the electrical work the Hillas Electric Co. tendered $2,997.65 and Bert L. Perry, $2,546.

Edmonton, Alta.—Contract let by Carroll-Wilson, Ltd., to McDougall, Trainer, McNeill, Ltd., Sugarman Building, Edmonton, for the erection of a one-story brick building at the corner of 102nd Ave. and 108th St.

Fort William, Ont.—It is stated that the C.P.R. Co. will submit a proposition to the city council which involves something like $2,000,000 in the erection of a railway hotel in this city. It is understood that if the proposition is submitted it will be voted on by the ratepayers at the January elections.

Galt, Ont.—The Perfect Machinery Co. will enlarge their building if the city will grant the company a $20,000 loan. A by-law will be submitted to the ratepayers.

Glace Bay, N.S.—School Board decided to call for tenders at once for the erection of a new Central School.

Grand' Mere, Que.—A movement is on foot for the erection of a Technical School.

Guelph, Ont.—The Chamber of Commerce is engaging in a programme for the establishing of new industries in the city. Of the concerns approached, four have intimated their readiness to build their plants at Guelph, providing the city is prepared to meet their offers.

Hamilton, Ont.—The sum of $74,800 will be advanced to the city by the Ontario Housing Commission for housing purposes.

Hamilton, Ont.—The British-American Oil Co. have been granted a permit to erect a concrete stable and garage on Burlington St. East at a cost of $8,000.

Hamilton, Ont.—The Dominion Canners, Ltd., have purchased a site of six acres in extent in the east end of this city. It is stated that the company intend to erect a $1,000,000 plant.

Hamilton, Ont.—Engineers of the Norton Co., of Worcester, Mass., were in the city recently letting contracts for the buildings which this company will erect here at the foot of Lottridge St.

Kingston, Ont.—Tenders addressed to the secretary, Board of Education, will be received up to noon, November 11th, 1919, for the erection of a Public School. Plans and specifications may be seen at the offices of the Board and the architects, Power, Son and Drever, Merchants Bank Chambers, Kingston.

London, Ont.—The city may erect large barns on its property at the corner of Waterloo and Horton Sts. next year at a cost of approximately $50,000. This question will be placed before the electors at the January elections for approval.

Maillardville, B.C.—The erection of a new municipal hall is under contemplation by the municipal council.

Moose Jaw, Sask.—Final plans for the new C.P.R. depot here show an approximate expenditure of $450,000. Engineer in charge of buildings for C.P.R., D. H. Mapes, Montreal.

Moose Jaw, Sask.—A campaign has been opened by the Great War Veterans for funds for the erection of a proposed Home and Memorial Hall. Chairman of Special Committee, W. McAllister. Estimated cost, $170,000.

North Vancouver, B.C.—A movement is on foot for the erection of a new public hospital. Clerk, J. G. Farmer.

Oakville, Ont.—Greenberg and Lentner Co., hat and cap manufacturers, may erect a factory here.

Oakville, Ont.—Alterations which will cost in the neighborhood of $35,000 are being made to the Presbyterian church. A 47-ft. Sunday School addition is being built at the rear, and a new church and vestry will be erected. W. H. Hocks is the general contractor.

Ottawa, Ont.—The question of erecting a memorial hall at a probable cost of $500,000 in connection with the new city hall, which must be erected in Ottawa in the immediate future, was submitted to the city council by the special committee appointed to consider the matter. If the council agrees, the ratepayers will be asked to vote on the matter at the January elections. Chairman of Special Committee, Capt. W. P. Grant.

Owen Sound, Ont.—Town Engineer Fleming has prepared plans for proposed improvements and alterations to the municipal building estimated to cost $5,000.

Owen Sound, Ont.—Plans are under consideration by the civic authorities for the construction of a new fire hall, including a central heating plant. Clerk, Chas. Gordon.

Penetanguishene, Ont.—The sawmill of the McGibbon Lumber Co. was totally destroyed by fire recently. Loss, $25,000.

Peterboro', Ont.—The old Cordage Co.'s buildings have been taken over by the city and $6,700 will be spent on repairs.

Petrolia, Ont.—A movement is on foot by the directors of the Corn Growers' Association, Live Stock Association and Poultry Association for the erection of a new winter fair building.

Portage la Prairie, Man.—Plans are under way for the erection of a rink, estimated to cost $10,000. Further information from W. R. Sexsmith.

Port Haney, B.C.—The erection of a fruit cannery and box factory here by Gillan and Edgett, of Vancouver, is announced.

Regina, Sask.—The Poole Construction Co. is erecting a warehouse at the corner of Hamilton and Eighth Ave. at a cost of $20,000.

Regina, Sask.—Contract let to the Poole Construction Co. for the erection of a $12,000 warehouse for the Winnipeg Ceiling and Roofing Co.

Regina, Sask.—The Merchants Bank of Canada will erect a new bank and office building on Eleventh Ave., between Scarth and Cornwall Sts. The building will be of dressed stone, steel and brick construction, fireproof throughout, and will cost over $75,000. Local manager, John J. Galloway.

Renfrew, Ont.—Renfrew has carried a $25,000 by-law for the construction of a new fire hall in which will be installed a central heating plant. Clerk, J. A. Devenny.

Rossland, B.C.—The Consolidated Mining and Smelting Co. of Canada will erect a large concentrator either at Trail or Rossland. The plant, which will involve an outlay of $1,000,000, will have an area of about an acre. The buildings will probably be of steel, with gunnite walls and concrete floors.

Sarnia, Ont.—Board of Education approved the plans for the erection of a one-story portable school.

Saskatoon, Sask.—A by-law will likely be submitted to the ratepayers at the next elections authorizing the issue of debentures to cover the construction of a hospital estimated to cost $200,000. City commissioner, C. J. Yorath.

South Vancouver, B.C.—It is probable that the proposed new High School will be located at the municipal grounds.

Squamish, B.C.—Mr. Hudson, of Everett, Wash., is investigating the feasibility of establishing a pulp and paper mill here.

St. Boniface, Man.—The Prest-O-Lite Co. will erect a new battery plant factory and offices.

St. Catharines, Ont.—Hon. Dr. Cody, Minister of Education, has notified the Collegiate Board that the government grant to the school will be paid this year on condition that the board, within the next three months, buys a site for a new school building. The question will likely be submitted to the ratepayers at the January elections.

St. John, N.B.—School Board proposes to erect two new schools.

St. Thomas, Ont.—Plans for a modern Labor temple, to be built by the I.L.P., of this city, and the U.F.O., of West Elgin, are now under way.

St. Thomas, Ont.—The Canada Iron Foundries have been granted a permit to erect a building at the corner of Woodworth and First Aves. at a cost of $12,000.

St. Thomas, Ont.—Contracts for the erection of a bank building at the corner of Flora and Talbot Sts. for the Molsons Bank have been let to local contractors as follows: General contract, A. E. Ponsford, Ltd.; plumbing and heating, Hamilton and Stott, and electric wiring, Roberts and Sandham.

Sydney Mines, N.S.—The Royal Bank of Canada proposes to erect a building here to cost approximately $60,000.

Toronto, Ont.—The first constructive work on the new Electrical Building, University of Toronto, has been commenced.

Toronto, Ont.—George E. Gooderham has been granted a permit to build an $85,000 garage on the west side of Sheppard St., near Richmond St.

Toronto, Ont.—The veto was put on the plan to erect a couple of public lavatories at a cost of $15,000 at Hanlan's Point by the Board of Control.

Toronto, Ont.—The north-east corner of Lee Ave. and Queen St. East has been purchased by the Canadian Bank of Commerce as a site for a branch bank.

Toronto, Ont.—City Architect Pearse has issued a permit to the Chase Tractor Co. for the alteration of their building at 28 Atlantic Ave. at a cost of $40,000.

Toronto, Ont.—A permit has been issued to the Ideal Bedding Co. for alterations and addition to their factory on the west side of Jefferson Ave. at a cost of $80,000.

Toronto, Ont.—Joseph Price and Sons have been granted a permit for the erection of 72 semi-detached private garages on the south-west corner of Woodbine Ave. and the Kingston Rd. at a cost of $4,300.

Toronto, Ont.—At a recent conference at Hamilton of those interested in the establishment of a large winter live stock show, Toronto was decided on as against Hamilton for the site. It will be located at the Exhibition Grounds. The project involves the expenditure of about $1,000,000.

Toronto, Ont.—Hon. Dr. Cody, Minister of Education, recently announced that under the joint Federal and Provincial scheme for encouraging technical and industrial education, grants are to be paid to municipalities to the extent of 50 per cent. of the cost of buildings and equipment especially provided for technical and industrial day or evening schools and classes.

Toronto, Ont.—Parks Commissioner Chambers has recommended the expenditure of $30,000 out of next year's estimates upon the erection of a shelter and public lavatories in the Hanlan Memorial Park. Commissioner Chambers also intends to submit plans for similar buildings in Island Park and High Park at an estimated cost of $50,000 each, in Riverdale Park at $30,000 and in Reservoir Park at $20,000.

Toronto, Ont.—The Advisory Industrial Committee of the Board of Education has concurred in the recommendation of Dr. A. C. McKay, principal of the Central Technical School, that $200,000 be placed in the estimates for 1920 to provide one-half the cost of the erection and equipment of a branch Technical School on Greenwood Ave., Riverdale.

Toronto, Ont.—City council proposes to build a new administration building on Albert St. for the police department and court rooms to relieve the congestion in the city hall. Chief Grasett and two of the police commissioners will visit cities in the United States with a view to ascertaining ideas for the erection of new quarters.

Trenton, Ont.—Work will start at once on the erection of a skating rink. Clerk, J. W. Delany.

Vancouver, B.C.—A scheme is under way here for the erection of a co-operative apartment house at a cost of nearly $600,000.

Vancouver, B.C.—The erection of new buildings for the Boys' Industrial Home at Jericho are being considered by the provincial government. Provincial secretary, Hon. J. D. MacLean.

Vancouver, B.C.—A permit for the construction of a one-story building for a machinery storage warehouse has been taken out by the British Columbia Sugar Refinery Co. Estimated cost, $2,000.

Waterford, N.S. — The Dominion Steel Corporation, through President Mark Workman, has donated $25,000 towards the erection and establishment of a General Public Hospital here. It is understood that work on the proposed hospital will begin immediately.

Windsor, Ont.—Plans have been prepared by A. H. McPhail, architect, for the erection of a school estimated to cost $400,000. Reinforced concrete and steel construction.

Winnipeg, Man.—Contract let to Thomas Kelly and Sons to construct a showroom at the City Light and Power Building. Estimated cost, $23,000.

Winnipeg, Man.—The Dominion Bank has purchased the north-west corner of Kennedy St. and Portage Ave. and next spring will proceed with the erection of a handsome bank building.

Winnipeg, Man.—The city council granted the Grey-Ogeltree Motor Co. permission to erect a public garage, 100 ft. by 140 ft., on the east side of Burnel St., between Portage Ave. and St. Paul Ave.

Woodstock, Ont.—The Brunswick Canadian Products Co. will erect a $200,000 plant here. Further information from President Rea, of the Board of Trade.

York County, Ont.—The Great War Veterans' Association is urging upon the county council the erection of a clubhouse.

York Tp., Ont.—The township council will shortly issue $200,000 worth of debentures to cover the cost of the erection of two schools in School Section No. 15.

York Tp., Ont.—Tenders will be received by John A. Martin, secretary, York Township Housing Commission, 40 Jarvis St., up to 12 o'clock noon, Wednesday, November 12th, for the furnishing of material and the erection of 15 brick dwellings.

MISCELLANEOUS

Calgary, Alta.—The commissioners recommended to the city council the installation of a complete new fire alarm system at the General Hospital at an estimated cost of $1,875. City clerk, J. M. Miller.

Deseronto, Ont.—The town council awarded a contract to Harry Hall to install a new fire alarm system for the town.

Glace Bay, N.S.—The question of a drydock for Glace Bay will be presented to the Dominion government by the Harbor Committee, of which Stuart McCawley is chairman.

Saskatoon, Sask.—The following by-laws will be submitted to the ratepayers on December 8th: New pumps at pumping station, additional expenditure, $7,000; 4,500 k.w. turbine, additional expenditure, $60,000; grading road along river bank, from Avenue H to G.T.P. bridge, $5,000. City commissioner, C. J. Yorath.

St John, N.B.—Work is being pushed on the Courtenay Bay drydock and breakwater by the St. John Drydock and Shipbuilding Co. It is anticipated that a British shipbuilding firm will establish a mammoth plant in the vicinity of the drydock.

Toronto, Ont.—The Board of Control instructed the Parks Commissioner to submit a report, showing his plan of improvements for the Don River and ravines from the harbor improvements to the northern city limits, providing for a boulevard, acquisition of C.N.R. yards from the government and securing of ravines on right-of-way of the belt line to the northern city limits for a boulevard scheme and driveway similar to the civic programme on the Humber.

Toronto, Ont.—According to a statement recently made by Mayor Church, the following are among expenditures contemplated by the city council: New live stock arena, $1,000,000; new schools and sites, $1,500,000; new court house, about $1,500,000; harbor improvements, $2,000,000.

Toronto, Ont.—The provincial government has granted charters to the following companies: Farmers' Mining Co., Ltd., Toronto, capital $50,000; J. K. Carroll Construction Co., Ltd., Kingston, $40,000; Crookston Quarries, Ltd., Crookston, $300,000; Northern Ontario Great Mines Developing Co., Ltd., Hamilton, $2,000,000; Ontario Tie, Timber and Construction Co., Ltd., North Bay, $350,000; E. A. Lowry Power Equipment Co., Ltd., Guelph, $50,000; Skead Gold Mines, Ltd., Toronto, $5,000,000; Central Electric Supply Co., Ltd., Toronto, $150,000.

Toronto, Ont.—Tenders for annual supplies were opened by the Board of Control on Thursday, October 30th, and were all referred to the departments concerned for report on samples, etc. The prices were as follows:—

Asphalt.—Tender No. 1—$17.50 in tank cars, $23.75 in packages; No. 2, $48.56 packages; No. 3, $21.67 tank cars; No. 4, $20.23 tank cars, $26.10 packages.

Block, Vitrified Paving.—Tender No. 1, 3-in., $47.50; 4-in., $51.

Castings, Brass and Bronze.—Tender No. 1, 35c. phosphor-bronze, 35c tobin-bronze, 30c. brass; Tender No. 2. 46¼c. phosphor-bronze, 42½c. tobin-bronze, 43¾c. brass; Tender No. 3, 65c. phosphor-bronze, 37¼c. brass.

Pipe, Lead, per 100 lbs.—Tender No. 1, $10.25; Tender No. 2, $10.50; Tender No. 3, $10.50.

Water Pipes, Cast-iron, per length.—Tender No. 1, $7.60 for 3-in.; $9, 4-in.; $15, 6-in.; $20.25, 8-in.; $28.50, 10-in.; $38.60, 12-in.

Hydrants.—Tender No. 1, $107.26; Tender No. 2, $109; Tender No. 3, $102.

"Far and away the best book in English on the design of reinforced concrete."

Principles of Reinforced-Concrete Construction

By F. E. TURNEAURE, Dean of the College of Engineering, University of Wisconsin, and E. R. MAURER, Professor of Mechanics, University of Wisconsin.

Was so referred to in a review of the second edition which appeared in Engineering News. The new, THIRD EDITION, total issue, 20,000, which has recently been published in a thoroughly revised and enlarged form, more than ever emphasizes the superiority of this standard book for engineers and others engaged in construction work. The following chapter headings indicate its scope:

Properties of the Materials. Theory of Deflection of Beams. Shear and Bond Stress. Design of Beams. Deflection of Beams. Columns. Analysis of Flat Slabs. Building Construction. Arches. Retaining Wall and Dams. Miscellaneous Structures. Reinforced Concrete Chimneys. Tables and Diagrams.

xii + 485 pages. 6 by 9. Fully illustrated. Cloth, $3.75 net.

Treatise on Concrete, Plain and Reinforced

Materials, Construction, and Design of Concrete and Reinforced Concrete. By the late FREDERICK W. TAYLOR, M.E., Sc.D., and SANFORD E. THOMPSON, S.B. With chapters by R. Feret, William B. Fuller, Frank P. McKibben and Spencer B. Newberry. Third Edition, Total Issue, 21,000.

An unsurpassed book for practicing engineers and contractors. The comprehensive treatment of both plain and reinforced concrete in a single volume gives it an added value.

xx + 885 pages. 6 by 9. 262 figures. Cloth, $5.00 net.

Concrete Costs

Tables and Recommendations for Estimating the Time and Cost of Labor. Operations in Concrete Construction and for Introducing Economical Methods of Management.

By the late FREDERICK W. TAYLOR, M.E., Sc.D., and SANFORD E. THOMPSON, S.B.

Written to assist architects, engineers, and contractors in making accurate estimates of the cost of concrete works and structures.

xxii + 709 pages. 5¼ by 8. 81 figures. Cloth, $5.00 net.

Plain and Reinforced Concrete Arches

By J. MELAN. Authorized Translation by D. B. Steinman, C.E., Ph.D.

One of the most thorough treatments of reinforced concrete arches in any language, giving analytic and graphic methods for the complete design of all types of concrete arches occurring in practice.

x + 161 pages. 6 by 9. 43 figures. Cloth, $2.50 net.

Valves, Stop.—Tender No. 1, $27.65, 3-in.; $33.15, 4-in.; $38.30, 6-in.; $68.40, 8-in.; $111.40, 12-in. Tender No. 2, $15.10, 4-in., with sockets; $16.78, 4-in., with flanges; $26.70, 6-in., with sockets; $28.50, 6-in., with flanges; $40.27, 8-in., with sockets, $43.20 with flanges; $72.14, 12-in., with sockets, $80.32 with flanges; Tender No. 3, $26, 3-in.; $31.25, 4-in.; $35.25, 6-in.; $62.50, 8-in.; $104.50, 12-in.; Tender No. 4, $32.50, 6-in., with sockets; $36.25, 6-in., with flanges; $72, 8-in., with sockets, $80 with flanges; $81.10, 12-in., with sockets, $90 with flanges.

Wood Block, Treated.—Tender No. 1, $2.06, 3 x 3-in. long-leaf yellow pine; $2.36, 3 x 3½-in.; $2.06, 3 x 4-in., plain blocks, $2.61, 4 x 4-in.; $2.51, 3 x 3½-in. lug, $2.21, 3 x 4-in., $2.76, 4 x 4-in., f.o.b. Mobile, Ala. Tender No. 2, $3.06, 3 x 3-in.; $3.48, 3 x 3½-in.; $3.87, 3 x 4-in.; $3.29, 3 x 3-in. lug blocks; $4.11, 3 x 4-in.

Liquid Chlorine, per ton.—Tender No. 1, $2.75; Tender No. 2, $2.40.

Mineral Dust.—Tender No. 1, $6.65 per ton.

Vancouver, B.C.—At a recent meeting held by the Harbor Board to hear the views of the members of the Shipping Federation on general harbor improvements, the federation went on record as being unanimously in favor of placing the improvements on Burrard Inlet. The present improvements suggested are a double-deck fireproof dock, 1,200 ft. long, with two two-story freight sheds at least 125 ft. in width, to extend the full length of the pier, and to be equipped with internal elevators and outside cranes. The Shipping Federation also considers it absolutely necessary that first-class drydock facilities be installed. Chairman of the Harbor Board, Mr. Kirkpatrick.

Victoria, B.C.—The provincial government has granted certificates of incorporation to the Canadian Water Wheel Co., Ltd., Vancouver, capitalized at $100,000, and the Campbell Rotary Pump Co., Ltd., Vancouver, also with a capital stock of $100,000.

Tenders Called For

LIGNITE UTILIZATION BOARD OF CANADA

Sealed tenders for briquetting machinery will be received by the Lignite Utilization Board of Canada at its office, 80 St. François Xavier Street, Montreal, P.Q., until 12 o'clock noon, December 14th, 1919.

Each tender must be made upon the proposal form provided, and must be accompanied by all the information required.

Copies of specifications and form of proposal may be obtained from the Secretary of the Lignite Utilization Board upon application.

The Lignite Utilization Board of Canada does not bind itself to accept the lowest or any tender.

LESSLIE R. THOMSON, Secretary. R. A. ROSS, Chairman.

Montreal, P.Q., November 1st, 1919. 373

Steam Turbine Driven Turbo-Blower Set

With Condensing Plant. For quick delivery from stock at very favorable price.

Condensed Advs.

Advertisements under this heading at following rates per insertion, with fifty cents per insertion as minimum rate in any case; "Positions Wanted," one cent per word; all other condensed advertisements, three cents per word. Payable in advance; 50 per cent. extra if charged.

GOOD OPENING for ambitious young man, graduate in Mechanical Engineering, preferably under thirty years of age. Canada Forge Co., Welland.

WANTED.—Engineer-draftsman, 18 years' experience, Structural Steel, Plant Design and Maintenance, desires position of responsibility, executive or otherwise. Box 21, *Canadian Engineer*, Toronto.

CONSTRUCTION ENGINEER.—Young engineering graduate, whose experience has been mostly in the contracting field, to take charge of branch office in Toronto. Knowledge of purchasing materials required. J. B. Nicholson, Limited, Hamilton, Ontario. 371

MANUFACTURER in Eastern Townships, having good facilities and considerable experience in the production of a wide variety of machinery lines, desires to undertake the manufacture (for the Canadian or export trade) of American or English machinery. Full particulars gladly upon request. Box 396, *Canadian Engineer*, Toronto.

SPECIAL COUNTRY PLACE OFFERED.—For satisfactory reasons the owner offers his two hundred acres, with residence and garage, also two houses and complete sets of farm buildings, in an excellent situation. Many interesting, profitable and enjoyable features. Price, fifty-five thousand dollars. No encumbrance. Owner will make appointment to show prospective purchasers over the place. Address Box 680, Oakville. 370

FOR SALE

One second-hand Robb-Mumford boiler, cast-iron front and steel half-case; 70 h.p.; 100 lbs. working pressure, complete with fittings, iron safety valves, water gauge, etc.

One second-hand Ingersoll-Rand cross-compound motor-driven air compressor; cylinder dimensions, low pressure, 16-in. diameter, 14-in. stroke; high pressure, 10-in. diameter, 14-in. stroke; piston displacement per minute at normal speed, 534 cubic feet.

For further particulars, price, location, etc., write

403 McArthur Building,
369 Winnipeg, Man.

PATENT NOTICE.—Anyone desiring to obtain the invention covered by Canadian Patents Nos. 161,048 and 161,049, granted on March 2nd, 1915, to Arthur Heinsmann, of West Kensington, London, W., England, for Propylene Production and Glycerine Production, may do so upon application to the undersigned, who are prepared to supply all demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh & Co., 5 Elgin Street, Ottawa, Canada. Russel S. Smart, resident. 372

In accordance with a request received from the city councils of Port Arthur and Fort William, Ont., it was stated last week at the head office of the Hydro-Electric Power Commission of Ontario that steps will be taken at an early date to secure an expert valuation of the street railway system at the head of the lakes. The decision to have the "Hydro" undertake this work was reached at a joint meeting of the two councils.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Hydro-Electric Power Development at High Falls

Net Head of 80 ft. Utilized at Power Site on the Mississippi River by the Hydro-Electric Power Commission of Ontario—Details of Dam, Intake, Gate House, Pipe Line and Power House—Surface Area Method of Proportioning Materials Shows Excellent Results in Construction of Concrete Dam

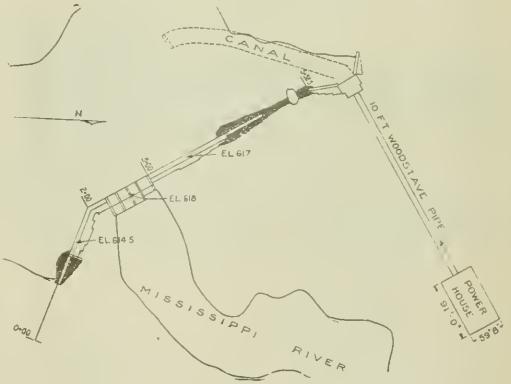
AT HIGH FALLS, on the Mississippi river, in the southern part of Lanark county, Ont., about 25 miles northeast of Perth and ½ mile above Dalhousie lake, the Hydro-Electric Power Commission of Ontario is developing a power site and installing hydro-electric machinery with total capacity of 3,600 h.p. This plant will be the fifteenth generating station to be owned by the "Hydro" Commission, and two others are also under construction, the Nipigon plant (see *The Canadian Engineer*, June 12th, 1919, issue) and the great Queenston undertaking (see the following issues of *The Canadian Engineer*: August 28th, 1919; November 21st, 1918; September 26th, 1918; and June 20th, 1918). The fourteen other plants owned by the "Hydro" are the following:—

Wasdell's Falls, Eugenia Falls, Nipissing Power Co., Erindale Power Co., Trenton, Campbellford, Frankford, Auburn, Fenelon Falls, Carleton Place, Ontario Power Co., Big Chute, Healy Falls and South Falls.

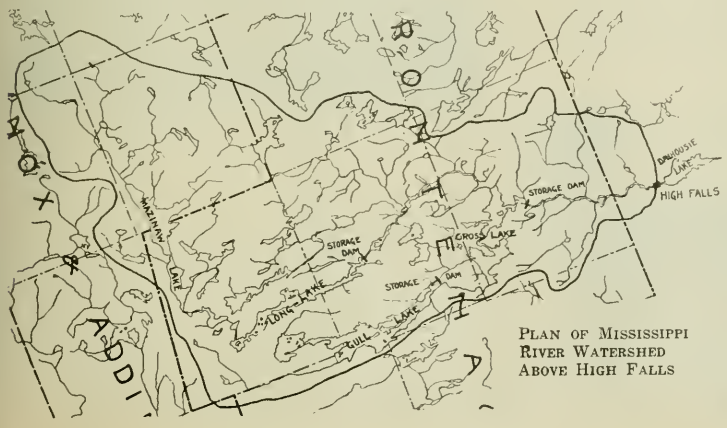
The first two mentioned—Wasdell's Falls and Eugenia Falls—were constructed by the "Hydro," but all of the others were purchased from the former private owners, although in the case of the four last-mentioned plants, the "Hydro" has built extensive additions.

The drainage area of the Mississippi river above High Falls is approximately 450 square miles. The first complete year for which run-off records were obtained by the "Hydro" was November, 1915, to November, 1916, for which twelve months the maximum run-off was 2,940 c.f.s., and the minimum 214 c.f.s., with a mean of 776 c.f.s., or a run-off depth of about 23 inches on the drainage area. For the following year, the maximum run-off was 2,060 c.f.s., the minimum 72 c.f.s., and the mean 426 c.f.s., or a run-off depth of about 12.8 inches on the drainage area. For the year November, 1917, to November, 1918, the maximum run-off was 2,530 c.f.s., the minimum 186 c.f.s., and the mean 499 c.f.s., or a run-off depth of about 15 inches on the drainage area. The watershed is still fairly well forested. The average run-off for the three years recorded was 567 c.f.s.

The plant that is being installed requires 540 c.f.s. when operated at maximum capacity. The water is used under 80 ft. net head. There are three horizontal, double-runner double-discharge hydraulic turbines; one of them is connected to a single generator, but each of the other two turbines drives a generator at each end of its shaft. This is not a matter of present design, but is due to the fact that



GENERAL PLAN OF HIGH FALLS DEVELOPMENT



PLAN OF MISSISSIPPI RIVER WATERSHED ABOVE HIGH FALLS

practically all of the hydraulic and electrical machinery for this plant was purchased at a low price, as used equipment, from the Hannawa Falls Power Co., of Potsdam, N.Y.

There is ample storage area above High Falls, as the Mississippi river flows through a chain of many lakes of various sizes, including Cross, Gull, Long, Mazinaw, Mud, Mississagagon, Kashwakamak, Buckshot and Grindstone lakes. The required storage dams on these lakes are already built and are owned and operated by the Mississippi Improvement Co., a private company that was organized by the power users who have developed other sites further down the river. The expenses of the Improvement Co. are met by assessments on all of the power users on the river, in

Excavation for Canal, Looking Downstream

proportion to the power developed. The Improvement Co. has acquired the necessary flowage rights on the various lakes. The chief storage dams are those at the outlets of Cross, Gull and Long lakes, and are rock-filled timber cribs. There is also a pondage area of over 500 acres behind the new concrete dam that is being built at High Falls by the "Hydro," this dam also increasing the available head by approximately 12 ft. The "Hydro" purchased the power site at High Falls two years ago from its private owner. The "Hydro" was already a member of the Improvement Co., on

Looking Upstream Above Dam Site

account of its ownership of the Carleton Falls plant further down the Mississippi river.

The accompanying general plan of the development indicates that the concrete dam at High Falls consists of a sluiceway section 76 ft. long, flanked on the south by an overflow section 104 ft. long, and on the north by a gravity section 112 ft. long, and terminating at the south in a core-wall section 38 ft. long and at the north in a core-wall section 140½ ft. long, the north core-wall section being sealed to the gate house by a wing wall 40 ft. long.

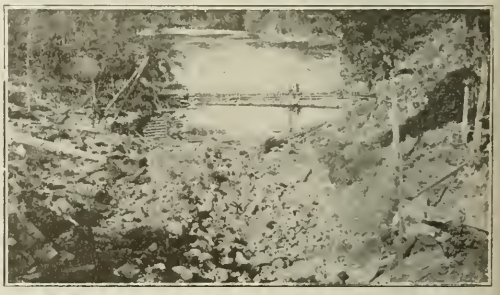
Looking Downstream Below Dam Site

The total length of the dam and wing wall is about 510 ft. This is about the correct length of the whole dam as constructed, but since the lay-out was made from which the accompanying general plan was copied, the dam was located slightly further upstream, with a consequent lengthening of the overflow section and a shortening of the northern core-wall section. The overflow section as constructed is also more nearly on a straight line with the remainder of the dam than is indicated by the accompanying general plan.

The four sluiceways each have a 14-ft. clear opening. Each of the four rollways is 8 ft. 7¼ ins. wide at top, with a batter of 9 in 12. The reinforced concrete deck is 17 ft. 4 ins. wide. The height of the top

Portion of Sluiceway Section of Dam, Showing Three of the Four Rollways

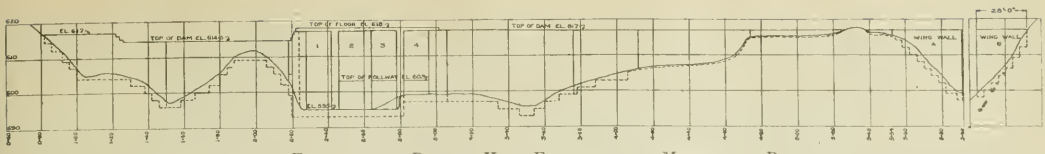
of the deck above the base of the dam is about 26 ft. for sluiceways Nos. 1, 2 and 3, and about 22 ft. for sluiceway No. 4. The clearance from the top of the rollways to the deck is 14 ft. 2 ins. The deck is 10 ins. thick. The piers have a batter of 7½ in 12. The overflow section has a top width of 4 ft. 5½ ins., and a batter of 7 in 12. The gravity section has a top width of 3 ft. and a batter of 7 in 12. The core walls have a maximum thickness of 2 ft., and a minimum thickness of 1 ft. The rock fill is 6 ft. wide at top and has



Power House Site Before Unwatering, Looking Along Pipe Line

a 1 to 1 slope on each side. The whole dam rests upon a rock foundation.

A canal, or intake channel, has been excavated for a distance of about 247 ft., extending upstream from the gate house at the north end of the dam. After the removal of the cofferdam that was built in order to divert the flow of the river and so unwater the site of the dam, this channel will be entirely under water excepting for a distance of 150 ft. from the gate house. The bottom of the canal is 8 ft. wide, and the sides are sloped 1½ to 1. The bottom and sides are protected by riprap excepting where they are in solid rock. The bottom of the canal is level for 100 ft. from the

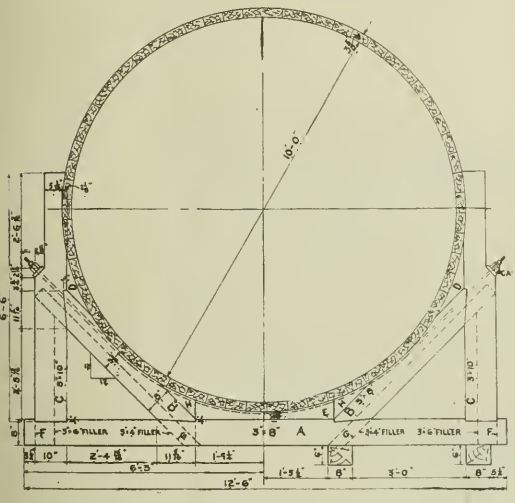


Elevation of Dam at High Falls, on the Mississippi River

gate house, then the grade is 2% for 100 ft., then 4% for 36 ft., and 40% for about 11 ft. at the intake.

The gate house substructure is 27 ft. wide by 30 ft. long and 22 ft. high to the floor of the superstructure. Behind the racks the width tapers to 17 ft. The water section varies from 20 ft. in width by 13 ft. in height to a circular section 10 ft. in diameter, ending in a reinforced concrete elbow which connects with the continuous-wood-stave pipe line leading to the distributor in the power house.

The wood-stave pipe line is 10 ft. inside diameter, approximately 320 ft. long, and is built of British Columbia

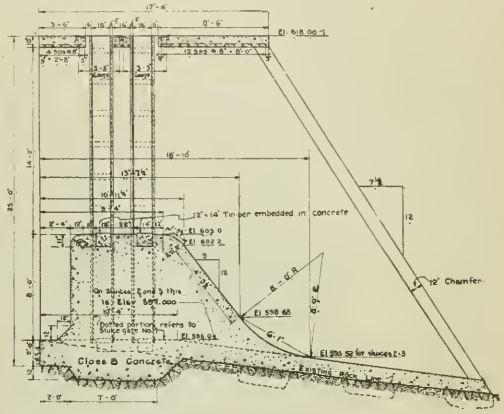


Wood-Stave Pipe, Showing Saddle Details

fir staves 3⅝ ins. thick. It is supported by timber saddles spaced at 6-ft. centres.

The pipe is laid to a 22.4% grade, the difference in elevation between the two ends being about 70 ft. It is banded with 1,025 bands (⅞-in. diameter) of two sections each, these bands being spaced as follows, starting from the gate house: 99 at 7 ins. c. to c.; 79 at 5½ ins.; 91 at 4¾ ins.; 108 at 4 ins.; 123 at 3½ ins.; 144 at 3 ins.; 157 at 2¾ ins.; and 224 at 2½ ins.

The bill of quantities for the pipe line included 2,050 shoes, 62 saddles, 124 saddle rods, 1,030 F.B.M. sills, 124

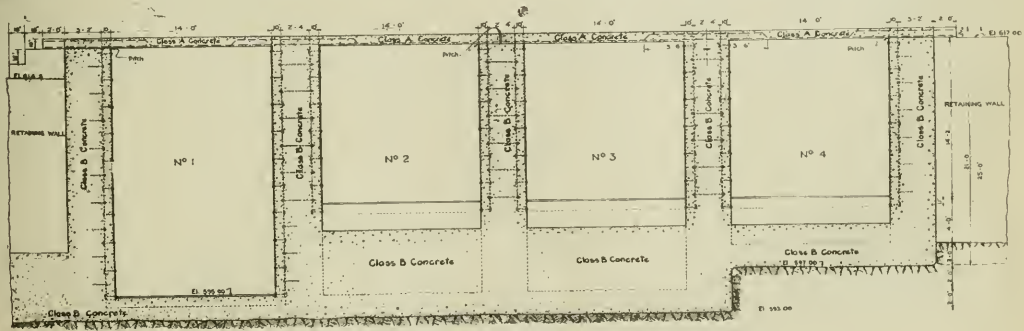


Cross-Section Through Sluiceway

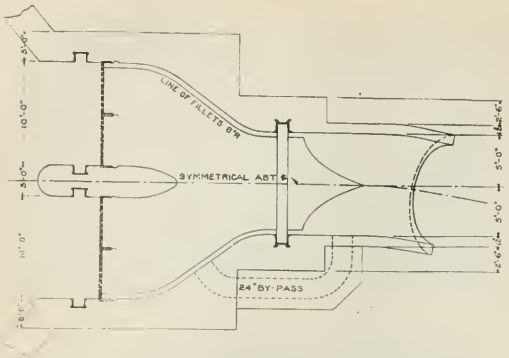
washers and 75 cu. yds. of 2-in. stone for use in bringing rock fill to grade.

The power house is situated on the river bank, and its substructure is approximately 94 ft. long by 62 ft. wide. The greater part of the power house substructure is mass concrete, but the distributor which carries the water from the wood-stave pipe to the turbines, is moulded in reinforced concrete. The turbine casings are steel plate, as are also the draft tubes. The tail water level is 532.5 when the forebay is at 614.0, so the gross head on the plant is 81.5 ft. at high level. The velocity in the pipe line at full load is about 6½ ft. per second.

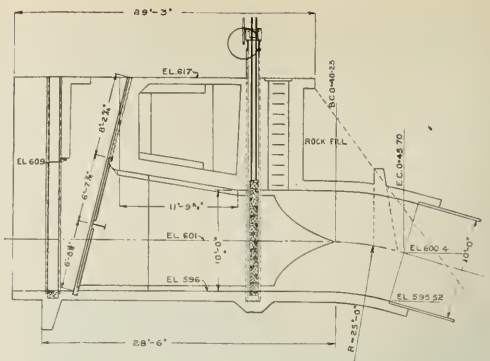
It is of interest to note that the Heath-Edwards surface area method of proportioning materials for concrete was used for the dam, this being the first time that it was used by the "Hydro." According to this system of propor-



Longitudinal Section Through Sluiceways of High Falls Dam



HORIZONTAL SECTION THROUGH GATE HOUSE



VERTICAL SECTION THROUGH GATE HOUSE

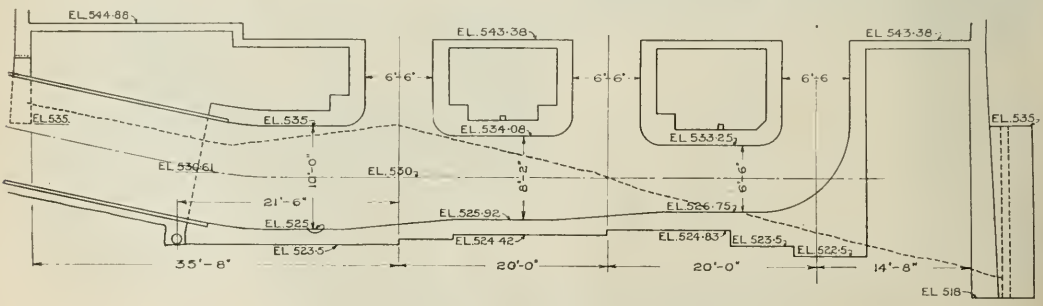
tioning, concrete is no longer specified as 1: 2: 4, 1: 3: 6, etc., but is called "Class A," "Class B," and "Class C" concrete. Class B concrete, which was used for the mass work at High Falls, is concrete developing a strength of 2,000 lbs. Class A concrete, which is used with reinforcing, is concrete developing a strength of 2,500 lbs. Test cylinders of Class B concrete taken from the forms at High Falls showed from 2,500 to 2,700 lbs. strength. At first lower results were obtained, but by cutting down the amount of water used and exercising greater care in the proportioning of the materials, the higher strengths were soon secured. Some samples of Class A concrete did not fail at 4,000 lbs., which is the limit of the "Hydro's" machine, so they were held there for three minutes and then tested no further. Crushed stone and gravel were used as aggregate. The stone is a trap of high quality.

Work on the High Falls plant started in October, 1918, and is now about 75% completed. The dam is finished, the gate house partially constructed, the foundations and walls for the power house are poured, the canal has been excavated and the pipe line graded. The pipe has not yet been constructed but the material is on the job, as is also all of the hydraulic and electrical machinery for the power house. The plant will probably "turn over" next spring. It will supply power to the "Hydro's" Rideau system at 23,000 volts, 3-phase, 60 cycles. The construction is being handled throughout by the construction department of the "Hydro." The wood-stave pipe was supplied by the Pacific Coast Pipe Co., Ltd., of Vancouver. The structural steel was fabricated by the Dominion Bridge Co., Ltd., of Toronto and Montreal. The cement used was purchased from the Canada Cement Co., Ltd., and the reinforcing steel from the Steel Co. of Canada, Ltd., of Hamilton

DAM SITE, SHOWING COFFERDAM FOR DIVERSION OF STREAM DURING CONSTRUCTION

Hon. Sir Adam Beck is chairman of the Hydro-Electric Power Commission of Ontario; W. W. Pope, secretary; and Frederick A. Gaby, chief engineer. The design and construction of the High Falls plant, with the exception of the electrical work and the power-house superstructure, are under the direction of the Commission's hydraulic depart-

(Concluded on page 467)



LONGITUDINAL SECTION ALONG CENTRE LINE OF POWER HOUSE

Town Planning, With Special Reference to Ottawa

Planning and Production Go Hand in Hand—The Problems of the Highway and the Railway—Some Notes on the Capital's Present and Future Problems—Address at the Recent Town Planning Conference in Ottawa

By NOULAN CAUCHON
Consulting Engineer and Town Planner, Ottawa

THE principal thing about town planning—at any rate, one of the things that we must bear in mind—is that a city cannot live unto itself any more than can an individual. That is why we have been advocating the benefits of regional planning. The surroundings of a city are what the city depends upon; the city is merely a market of exchange; and transportation is the flux of exchange. By adopting the principle of regional planning we are endeavoring to bring about the intensive cultivation and development of land around the cities, from which the cities derive their supplies.

I want to give some of the principles upon which we carry out town planning—the angle from which we work. Now, in analyzing the town planning problem I divide it primarily into threee main issues: Ethics, economics and art. These are but different manifestations of natural law, of the organic law of life.

Town planning is fundamentally a question of ethics. Ethics are those customs of righteousness which become necessity in the evolution of the race in prevailing against extermination.

Ethics means the conservation of energy—above all, of human energy, the most precious of all. That is the point of view we are taking in Canada; it is the conservation of human energy, the unit of production. All wealth, after all, comes from production; it is based fundamentally upon the efficiency of the unit of production. So we are directing our efforts mainly to that organic law of life, production. We have to abolish the slum and we have to eliminate congestion for that purpose. Town planning is a gospel of social regeneration; we are looking at it altogether as a matter of sociology.

Economics are but the conversion of energy in the maintenance of life—production. Economics are but the laws of nature translated into current terms, usually into dollars and cents as the most convenient common denominator to which things different by nature can be brought to equation and solution. In other words, to engineers I may say in particular, the economics by which we compare everything by dollars and cents is, quite outside of the matter of money, the finest decimal scale that the world has ever had for a common denominator to which you can reduce things, as I have said, to an equation and solution for the conservation of energy. The values of horses differ, the values of farms differ, but when you get down to the decimal scale of dollars and cents you get a relative value for the time being; you get your scale and you get your perspective. That is why you must not think we are always thinking of money when we are giving you economic ideas.

Future Depends Upon Production

Art is simply expression sought—I do not always say, obtained—sought through the properties of mind and of matter, of truth absolute, inherent in the nature of things. Technique is but the tempered tool in master hands.

In the matter of organic planning, we are immediately concerned with two great factors, land and transportation, productivity of the soil and the trade routes. These are the two factors which from time immemorial have influenced the migrations and the evolution and the revolutions of mankind. In other words, our whole hope of going on as a nation must be based upon production; where production fails you get political disintegration such as happened in the Roman Empire, and the city and country go to pieces.

Therefore, to get the finest production and the highest results we must have the highest human unit of efficiency; that is the ethics of the thing, and it is upon that that we found our endeavors in the matter of housing. That is why housing is such a very important thing in the life of the nation. It is not philanthropy; it is not religion; it is just pure ethics. It is a matter of what is due to man as his right; and as a result, the efficiency which that man and his children will attain.

Now, under the head of economics, two of the most important things we have to deal with are under the head of transportation. In other words, before you begin to replan a city, the first thing you have to deal with is the matter of your railway transportation. I have attended a number of conferences on this subject, and I have found that people almost invariably refer to the railway as a necessary evil; as something that you have to put up with. But there is no evil at all about a railway. The railway is a splendid means of transportation, both of people and of freight, at the lowest possible rate. It should seek to follow the line of least resistance, but it is not by any means an evil. I do not say that there are not evils connected with railways; sometimes they are evilly located; sometimes they are mismanaged; but fundamentally the railroad is the sinew of life and is essential to the transportation of the country.

Railways as Decorative Feature

I see no reason why your railway station and your railway facilities should not be as fine a decorative feature of your city as is any other of the functions of life—for it is a function of community life; it is inherently fine and beautiful if you treat it so, if you give it proper expression.

The trouble with the railways in most of our cities in this country is that the railway got there first. In the old days property was not so valuable and the railways went where it was most convenient to go and where it was cheapest to build the road; then the cities grew up around them and eventually there came a condition of congestion.

When you are taking hold of a city and developing it and planning it for the future, you have to ascertain what is the path of least resistance in which you can put that railway, because if it is not in the right place, just to the exact measure that your city is prosperous will there be an inducement, an economic justification, for that railway leaving its bed and going, like a great stream in a deep valley, to the lowest point where the flow will be uninterrupted. The point is, that the more successful and the greater your city becomes, the greater will be the danger of the whole thing being upset because the railway is not in the right place. Town planners can see that a railroad roving around is liable to upset their best laid plans; so you have to get your transportation system settled first and foremost.

Your next problem is that of the arterial highways. By "arterial highway" I am going to refer to highways reaching from the centre of the city clear out into the surrounding country from which the city draws its supplies. We are trying to abolish that hard and fast line between the city and the country, because one merges into the other; it is the proper relation of things.

I am claiming that the arterial highway should be located and developed and maintained on the same principle as the railways, that is, on the principle of the ruling grade. Motor traffic has come to stay.

As I stated in a report which I made a short while ago in connection with the separation of grades in cities, it has been the custom when you come to apply to the Railway Commission for separation of grades, for the railway to state: "Our grade is so and so," 0.5, 0.6 or 1% as the

case may be. "Of course, in the separation of grades with the street you cannot depreciate the railway grade because if you do you affect the haulage capacity of the railway"; and invariably the highway has had to be sacrificed. Now, I maintain that neither the railway grade nor the highway grade should be sacrificed. In the separation of these grades the cost should be proportioned in accordance with the importance of the two; but the fundamental point is that the arterial highway ruling grade is just as important as the railway grade.

More Power on Highways

We have to-day, or we had at the close of the war, about 5,000 locomotives in Canada, which, taken at an average of about 300 h.p. each, means 1,500,000 h.p. We have also 250,000 motor cars on our roads, which, at the low average of 20 h.p., means 5,000,000 h.p. That motor traffic is going to double, treble, quadruple, within our easy knowledge; therefore you will have a horsepower of not 5,000,000, but possibly 50,000,000 in the future.

The highway traffic of Canada and of the United States is going to be a greater factor in connection with our transportation than the railway traffic, because you must recognize that everything that is carried on the railways is first carried over the highways, and an enormous amount of the stuff that is carried over the highways never reaches a railway. So your highway traffic, if you have proper roads, will eventually be greater than your railway traffic and this is a matter which will have to be taken into consideration; you will have to preserve your ruling grades for these highways the same as you do your railway grades.

We have 24,000 level crossings, in Canada, or thereabouts, so we have some work cut out for us to separate these grades. They are not all equally dangerous, but the economic factor is there of separating them and at the same time protecting the grades.

Local vs. Through Highways

There are two classes of roads, the local development and the through highway such as the Toronto and Hamilton highway. We are expecting that the Toronto and Hamilton highway will be carried through for connection between Niagara and Hamilton and then on to Brantford, London, Chatham, Windsor, Detroit and through. But if these roads are to become "through" highways, they must be dealt with on the same principle as the great railways of this country; that is to say, they must go on independent rights of way without any frontage.

I may say, by the way, that some remarks I made with regard to the Toronto and Hamilton highway were taken up wrongly; and in that connection I had to address a letter to one of the highway's commissioners in Toronto. The Toronto and Hamilton highway is the best example of the local development road that can be found anywhere in the country; it is fast becoming a village from one end to the other. Now that very feature of the local development is going to choke the usefulness of that road as a "through" highway. Therefore we shall have to have both; we shall have to have good local highways as well as "through."

Triplication of Service

One of the first things that was proposed in the planning of Ottawa, back in 1909-10, was in connection with these railways that enter the city. As is the case in many cities in the United States and Canada, we had a triplication of services; we had three railways coming into the city, each with an independent entrance. That is absolutely unnecessary. Our national waste is perhaps more in the duplication of terminals than it is in the duplication of main lines, bad as that has been. About 80% of the cost of the land for a railway running, say, from Ottawa to the heart of Montreal, would be in the entrances to the two cities.

If you enter three railroads by three different entrances, you are triplicating not only the service; 160% out of 300% is absolute waste upon which the public have to pay interest. We are just waking up in Canada to the economic fact that the public pays the piper. When the railways come near to the margin where they cannot meet their obligations, the Railway Commission has to come to their assistance by permitting them to raise their rates, and a great part of that increase in rates has been necessitated by the policy of unwarranted duplication in the past. You cannot blame one person more than another. The whole of Canada has been developing during the last 25 or 30 years on a speculative policy, not on an economic policy; and when everybody in the country is speculating, you cannot expect that the government policy will not reflect the policy of the everyday man in the street.

We were building railway lines as fast as we could, stretching out over the country a skeleton system and trusting to the inflow of immigration to fill the vacant spaces. Then came the time when immigration stopped, the war broke out, and we suddenly realized that we were simply discounting the future. So we have to get down to economic methods, and one of the most economic things we can do with a view to reducing railway expenditure is to eliminate the duplication of terminals.

Union Terminals Required Everywhere

In other words, the order of the future is union terminals in all cities, whether those terminals be owned by the railways or by the respective municipalities. That is what we are attempting to do at the present time in Hamilton and in London.

The city of Hamilton, as an outcome of the scheme that has been evolved there, has applied to the Ontario legislature for, and has obtained, a special Act to enable them to build the terminals of the city as a municipal enterprise. I believe that Hamilton is the first city in Canada, possibly the first in America, which has undertaken and is preparing and authorized to assume the responsibility of building terminals as a municipal enterprise. Of course, they will be leased to the railways for operation. They are awaiting the outcome of the Bill which is now before parliament providing for the taking over of the Grand Trunk Railway System; when that is settled, the city will be enabled to deal with the companies whose rails come within the city's bounds.

So far as Ottawa is concerned, the three railroads which now come into the city by three separate routes, the Canadian Northern, the Canadian Pacific and the Grand Trunk, could be joined up 3½ or 4 miles out of the city, on the east, and brought in on a common entrance. They could come down the canal to the central station; a tunnel under the city would clear everything in the way of level crossings; then they could proceed out through the Chaudiere and the industrial section and so out of the city on a common route to the dispersal point 6 or 7 miles west at Britannia. The carrying out of that scheme would mean the elimination of the Grand Trunk line across the heart of the city and out to Britannia.

Eliminating the Railway Barriers

In the plan that was originally proposed, I suggested the elimination of some 21 miles of trackage, and some years afterwards 18 miles of that was adopted by the Ottawa and Hull Federal Plan Commission.

If the Grand Trunk passes to the government, one of the first things we hope they will do in connection with the beautification of Ottawa—not as a city in Ontario, but as the capital of Canada—is to eliminate this cross-town line and thus remove a very serious barrier to the development of the city. In the middle of that line, where it runs for ¾ mile through the heart of the city, there is a hole called the Bank street subway, and if you do not go via Bank street, you have to go round one of the ends of that stretch of line in order to get past. Any further opening of that barrier would cost the city $150,000. Several miles of that line are beyond the present city limits and will constitute a like barrier in the future; so the removal of that line and its conversion into a boulevard, parkway or a great highway, will not only remove a barrier but will also enable the city to avoid spending from $8,000,000 to $15,000,000 in the years to come in the construction of subways or under crossings.

But you cannot under cross in the case of every street; and where you do not, you are discounting your development. As a general principle, of course, we prefer to

elevate the roads in the case of these crossings, but it is purely a matter of circumstances.

Ottawa was not planned at all; like Topsy, it "just grew." The mesh of Ottawa streets is as bad as any you can find; it is a girdiron gone crazy, as may be said of almost every city in America where they have not taken hold of town planning. If we do not get this Grand Trunk right of way we will in time have to build other arterial highways through there; that means that instead of buying from one owner, we shall be buying from 1,500 or 2,000 owners. My advice to my brother town planners is this: Wherever possible see that the city purchases the right of way of any railroad that can be removed like this and takes it for a great highway.

Must Plan to Purpose

In regard to zoning, I maintain that you cannot plan except to purpose; you cannot plan unless you know what you are doing it for. If you are going to plan an industrial section, you want great broad streets, narrow sidewalks and blocks probably 500 ft. square. You have to provide for uninterrupted traffic; when one or two thousand men suddenly come out of a factory, they simply swarm down the road, which is at peak load at certain hours. If you are going to develop a high-class residential district, you want deep lots, broad frontages and boulevards; they can stand the carrying charges of the public improvements. Then, if you want a workman's industrial district, you must follow a certain plan—and here I absolutely agree with Mr. Veiller: I am in favor of small lots and small streets, because workmen's homes cannot stand the carrying charges of a great boulevard.

This is the mistake the Germans made in their town planning. In Berlin they had magnificent boulevards and six-story tenement houses for their workmen. Within limits these were architecturally beautiful; they were fine, costly buildings, and the effort to attain the beautiful was there and also in the broad boulevard. But the result was that these working men had to live in six-story tenement houses to pay the carrying charges, with as many as five courts in these great lots 500 ft. deep. Just before the war, the death rate from tuberculosis in these beautiful tenements was 2½ times as great as the death rate among the children brought up in the gutters of English towns. The explanation is very simple. Families live in two rooms. When the head of the house goes to work in the morning, he is not going to bring the children down and allow them to play where they will be run over by motor cars. The mother has to do the house work, and when the father comes home at night he is too tired and it is too late to take the children down to play. Besides, it is not satisfactory nor sanitary for a family to live in one or two rooms where they sleep, cook, eat, do the washing and everything else.

German statistics with regard to the health of the people are based on information respecting the efficiency of a man for military service at the proper age. Their statistics show that just before the war only 20% of the young men whose parents had been born in Berlin were fit for military service at the military age; and that was due to the condition of living which I have suggested. Moreover, it cannot be said that the German was not an orderly man; he was subjected to military training; he was amenable to rules and regulations with regard to cleanliness. There was never any suggestion that these people were not cleanly; the high death rate among these children was a result of a purely economic condition.

The Technique of Sociology

As I say, city planning is simply the technique of sociology. Regulations as to how high a house should be, as to how wide a house should be, as to how wide a street should be, and as to the distance between buildings—these are simply means of ensuring health; it is simply the technique of sociology, the ensuring to a man of living conditions which will give to him and to his children a degree of efficiency and a state of health that will enable him to go forward instead of backward.

In this planning of Ottawa, then, one of the main features is the grouping of railways and the elimination of certain rights of way and their translation into boulevards. I am going to discuss this matter as impersonally as I can; I do not agree with a good deal that is in the commission's plan.

As can be seen from the plan, a subdivision made up of lots of standard size is set apart, enough for a couple of million people. It is subdivided to the limit of site, in a manner which presupposes 50 by 100 ft. lots, to infinity. That is just the error of the gridiron plan magnified to infinity. You cannot select from it one section and say that that is to be a high-class residential section or a cheap workingmen's section—and when I say "cheap" I do not mean to say cheap in the nasty sense; I mean the securing of the best possible conditions for the very least amount of money. It is simply a question of taking into account a man's wages and allowing 15% for his rent—that factor varies between 10% and 25%—and a certain amount for the land. If the land is expensive, the purchaser may not be able to build his house with due regard to comfort and sanitation. Of course, the man who owns the land will get what he wants, and what is left will build the house—or, as is generally the case, will not build the house—and you get a condition lacking in sanitation and efficiency.

Location of Arterial Highways

I claim, therefore, that you cannot plan unless you know the purpose for which you are planning; that is why I say that the location of the great arterial highways is the next move after you deal with the railway situation. You may say: "We are going to make an industrial section of this part." Well, you may make it on the plan, but if your industrial section is planned on the top of a hill, the people simply will not haul their produce there. It is a fundamental law of nature; it is Newton's law of gravitation. Every ounce lifted and set down costs so much money. Man is also an animal; he likes to do things with the least effort. It is one of the fundamental principles of political economy that a man seeks to accomplish his ends with the least possible effort.

Special Conditions at Ottawa

This Federal District plan embraces Ottawa in the province of Ontario, and Hull in the province of Quebec. It would be very difficult to bring about here such a Federal district as there is at Washington. There are certain things applicable to the conditions in the District of Columbia that are not applicable at Ottawa. There is the fact that this proposed Federal District would embrace two different provinces, each with different laws. The suggestion has been made by some that we might have something like the London County Council—simply community control of physical features and public utilities, the legal twists and kinks being left with the various lawyers to disport with.

It is fundamental that water supply be protected. Many years ago the Ottawa Board of Trade took this matter up, and they asked me to delimit what should be the Federal District. I simply ran my pencil around the watershed and said: "You have to have control of your watershed; otherwise anything you may do for the purification and protection of your water supply may be nullified."

Must Control Water Supply

You have to control your water supply within the area that you are going to govern; otherwise you cannot guarantee sanitary conditions. One of the reasons, therefore, why we want to include both sides of the river in the Federal District is in order that we may secure control of the water supply and prevent the pollution of the river. At present there is noting to prevent the villages above the city—and they do it—from putting sewage into the river. Of course if the villages are far enough above the city, the aeration, etc., may obviate the danger; but this consideration has an important bearing upon the whole matter. It is true that we have legal means to stop it, but if we take steps in that direction, the people below will put us to the expense of building a purification plant. That is the position we are in. It is a case of you scratch my back and I will kick you,—not scratch yours!

(Concluded in next week's issue)

COMMITTEE FOR MONTREAL CONVENTION

JOHN A. KIENLE, secretary of the Water Works Manufacturers' Association, announces that the following have been appointed to serve on the entertainment committee for the next annual convention of the American Water Works Association, which is to be held next June in Montreal, Que:—

H. G. Hunter (chairman), of the New York Continental Jewell Filtration Co., Montreal; G. B. Greene, of the General Supply Co. of Canada, Ltd., Ottawa; T. W. Lesage, of the Montreal Water Works; T. A. Hutchinson, of Drummond, McCall & Co., Montreal; F. C. Laberge, consulting engineer, Montreal; John A. Kienle, of the Electro-Bleaching Gas Co., New York; and James J. Salmond, representing *The Canadian Engineer*.

The objects of the Water Works Manufacturers' Association are: "(a) The advancement of the interests of its members and of the water works associations; (b) the providing for and having custody of such exhibits of materials as may be made at the conventions; (c) the furnishing and distributing of all badges used at conventions; and (d) the establishment of friendly co-operation and relations with its members and with the delegates of the water works associations."

C. B. & C. I. NOW HAS DOMINION CHARTER

IN preparation for the second general conference of the Association of Canadian Building and Construction Industries, to be held January 27th to 30th, inclusive, at Ottawa, the executive of the association has issued a pamphlet briefly reviewing the association's work to date, as follows:—

"1. One meeting of the national council has been held in Toronto, defining the policy of the association, and drafting by-laws.

"2. Several smaller meetings of members of the council have taken place in Montreal, Toronto and Ottawa.

"3. The Montreal Builders' Exchange has been reorganized in accordance with the aims and objects of the Canadian Association, and is now known as 'The Association of Montreal Building and Construction Industries.' It is now organized in three main sections, viz.: general contractors, trade contractors and supply men.

"4. A branch has been organized at Sherbrooke, Que., and affiliation was later secured with the local board of trade.

"5. The contractors of Ottawa held a banquet and organized the Ottawa Branch of the association. A very successful industrial council has been formed.

"6. At a banquet of Toronto builders early this year the question of reorganizing as a Toronto branch was discussed, and the idea approved. No definite action has since been taken, as it was felt that a number of questions should be settled at the next annual conference before final action.

"7. Ever since the last conference in Ottawa the officers of the association have been consulted by the government as representing the building and construction industries of Canada. The government requested the association to send six representatives to the recent industrial conference, and we had a delegate on each of the two most important committees.

"8. We have been building up a connection with the National Federation of Construction Industries of the United States, and have been visited by the president, Ernest A. Trigg, and the secretary, John C. Frazee, who furnished us with valuable information.

"9. A Dominion charter has been obtained, thus giving the association a corporate existence."

The pamphlet also states that it is planned: (a) To invite the affiliation of existing local and provincial bodies; (b) to organize new branches throughout the Dominion; and (c) to promote a closer acquaintance and knowledge of conditions throughout the Canadian building and construction industries by various membership publications.

The association needs about $2,000 to finance requirements until the next conference, when a permanent membership basis will be arranged. Contributions of from $10 to $50 each are being requested by J. Clark Reilly, the acting general secretary.

NOVA SCOTIA POWER COMMISSION

AT the request of the Pictou County Light and Power Committee, a public meeting of the Nova Scotia Power Commission was held November 4th, in New Glasgow, in order that the citizens of Pictou County might have an opportunity of demonstrating to the commission the necessity of some immediate action in connection with the power situation in Pictou County. It was claimed that Pictou County, already a large and industrial community with great possibilities of expansion, is absolutely handicapped in competition with other parts of the country, due to the present high cost of power in that vicinity, even though it is a large coal-mining district.

It was shown that there is at present available a guaranteed market of at least 10,500 h.p., and that the municipality of Pictou County, being free from bonded indebtedness, is ready and willing to undertake the distribution of any power which might be supplied to it in bulk by the Nova Scotia Power Commission, either from hydro-electric or central steam plants.

Hon. Mr. Armstrong, chairman of the commission, assured the meeting that steps would be taken immediately to deal effectively with the situation as presented, and pointed out that although the commission had been in existence only six weeks, it is already prepared to make a definite recommendation to the provincial government and to take immediate action upon receiving the necessary authority in regard to the power situation in the vicinity of Halifax.

The Ontario Section of the American Society of Mechanical Engineers will hold a meeting at 6 p.m. to-morrow evening at the Engineers' Club, Toronto. Supper will be served. This meeting is to enable the members of the section to become better acquainted, and to decide questions of policy regarding the future of the section and the work for the coming winter. Brig.-Gen. C. H. Mitchell will deliver an address. The chairman of the section is Prof. R. W. Angus, and the secretary is C. B. Hamilton, Jr., of the Hamilton Gear and Machine Co., Ltd., Toronto.

Following is the schedule of the short courses in highway engineering at the University of Michigan as announced by Prof. Blanchard: Highway Transport, Prof. Blanchard. Feb. 2 to Feb. 6; Bituminous Surfaces and Bituminous Pavements, Prof. Blanchard, Dec. 1 to 19; Highway Laboratory Research, Prof. Bateman, Jan. 5 to 23; Highway Bridges. Prof. Gram, Feb. 9 to 20; Specifications and Contracts, Prof. Riggs, Feb. 9 to 20; Earth, Gravel and Broken Stone Roads, Prof. Bateman, March 1 to 12; Cement-Concrete Pavements, Prof. Blanchard, March 1 to 9; Brick Pavements, Prof. Blanchard, March 11 to 19; Highway Engineering Seminar, Prof. Blanchard, Dec. 1 to March 19. The fees for courses are from $5 to $15 each.

Morran & Beatty, Ltd., contractors, of Peterborough, Ont., have been awarded the contract for the hydro-electric power development at Grand Falls, on the Nepisiguit river, for supplying power to the Bathurst Lumber Co., of Bathurst, N.B., in connection with their lumber mills and new pulp plant. Two units will be installed, provision being made for a third unit. Each unit will be 4,500 h.p. The turbines will be of the vertical type, direct connected to generators. The turbines will operate under a head of 100 ft. The dam and power house—the former 450 ft. long—will be constructed of concrete. The power will be transmitted for 19 miles; the line will be constructed on steel poles. William Kennedy, Jr., of Montreal, is the hydraulic engineer, and Dr. L. A. Herdt, Montreal, the electrical engineer for the project.

WATER METERS A PROFITABLE INVESTMENT*

By W. H. Randall
Managing Director, Neptune Meter Co., Ltd., Toronto

THE general meter question has been before the public in the United States for some years, but in Canada it is only starting to become a live subject. Those who are closely connected with water distribution, have found that something in the way of a check must be done to offset the waste, due largely to the carelessness of the public, who in many cases allow their plumbing to become defective, and in others, who allow the water to run to waste down the sewer instead of closing the valve or tap after each operation.

This is a common practice in garages and other places where they have cement floors drained to the sewer. The washer drops the hose on to the floor and lets the water run until he is ready to use it again. Thousands of gallons of water are allowed to go to waste daily in this manner.

An important feature has arisen which practically makes it compulsory for every city to consider the selling of water by meter to-day. Filtration plants have become a necessity in practically all parts of Canada, and the pumping and filtering of water, with the cost of labor and the price of coal, is a very expensive proposition for any city. To allow people to use water indiscriminately, without any restriction, in the very near future will be a thing of the past.

Large Cost of Waste

One would at once ask why a man should pay for electricity and gas by meter and be allowed to take water just as he saw fit on a rate based upon the number of rooms in his house. I think that nobody would start a private water company upon any such basis as that.

The per capita daily consumption during the year 1918 in Toronto was 128 Imperial gals. Buffalo, N.Y., used 310 U.S. gals. per capita, while New Orleans, La., used only 64 gals. While we admit that there may be circumstances why cities would differ more or less in their per capita consumption, this should hardly be so great as the difference between Buffalo and New Orleans. Buffalo used about five times as much as New Orleans. Much of this, surely, must have been due to waste.

Scarcely anyone doubts the strong tendency of water meters, as of gas and electric meters, to prevent waste and leakage and to secure careful use. How far meters will accomplish this requires a very careful and exhaustive study.

In the United States, according to census figures, every million gallons of supply of water allowed to run to waste through leaking underground piping and bad plumbing costs a city (for operation and interest charges) $65 a day, or over $23,000 a year.

Flat Rate More Expensive

With our high tax rate and rapid increase in the cost of living, the financial advantages of checking leakage and other waste of water can hardly be exaggerated.

The metering of business properties is agreed to by all. It will surprise most people, however, to know that the average house-owner, as well as the city, gains by the installation of a water meter, and every tenement house owner in Toronto, for example, would gain by having a meter installed. Take an eight-roomed house under the present system of rating in Toronto:—

Eight rooms at 65c.	$ 5.20
Basin or tap in sink	1.25
One bath	1.25
Closet	2.00
Hose	1.00
Pair of laundry tubs	1.25
Total	$11.95

With four persons in the house, and taking a maximum use of 40 gallons a head through the meter, it would figure for the 12 months, 58,400 gallons. This at 13 cents net would only amount to $7.59 per annum by meter, while the flat rate shows $11.95. The minimum rate, however, in Toronto, for meter rent is $2 a quarter-year, which would mean $8 per annum, so a person with a meter in an eight-roomed house would at least save the difference between $11.95 and $8, or $3.95, providing that his plumbing, etc., was kept in proper condition.

From this it can be seen that anyone with a house of eight rooms or more would be better off by having a meter, and would pay for the same in a few years, even if he had to buy the meter himself.

My opinion on this question would be best expressed as follows:—

1. The water supply should be metered.
2. The meters should be purchased and installed by the city at its expense, and not by the property owners, as is often done at present.
3. The city should make all repairs to meters at its own expense.
4. The installation should be spread over five or six years.
5. A minimum rate should be established.

*Excerpt from an address delivered November 6th, 1919, at a meeting of the master plumbers of Toronto.

SWIMMING POOL MANAGEMENT*

By William P. Mason
Professor of Chemistry, Rensselaer Polytechnic Institute, Troy, N.Y.

OF course a swimming pool should be constructed in a satisfactory manner from an engineering standpoint. And it is especially desirable that the means of getting the water out of the pool should be carefully looked into. Several pools that I have had more or less to do with, have their outlets in the side. That is a very serious error. If there be any deposited matter in the pool that is to be gotten rid of, it is practically impossible to draw such sediment through any side orifice without nearly emptying the pool. If the orifice be in the floor, then the material can be pushed on top of the outlet grating and a very few turns of the valve handle in the pipe leading to the sewer will dispose of the sediment without difficulty and with small loss of water. With a pool, the size of ours at Troy, containing 100,000 gallons, unnecessary loss of water quickly runs into money and calls the attention of people who have to pay for it.

I have noticed that the side gutters are sometimes poorly designed. If they extend too far from the wall it is a very serious inconvenience; on the other hand, if they are covered by the overhang the swimmer cannot easily spit into them unless he is a dead shot, and in his efforts to do so he often misses entirely and the sputum gets into the pool, where it proves a most disgusting thing for a bather to swim against.

"Fill and draw" pools are usually filled and emptied about once a week. This type is getting somewhat scarce and water must be pretty cheap in order to allow of such a form of operation. More commonly, the water is continually circulated, as at the Rensselaer Polytechnic, is subjected to some system of improvement, and is replaced after long stated intervals. At Rensselaer we retain the same water for a year, making the change in August. That time is selected because the students are then away, and we can run out the old water, look things over and refill with less inconvenience. Throughout the year the same water is continually circulated by the pumps through the filters, of which we have four, each 4 ft. in diameter. Our rule is to chlorinate once a week with chloride of lime. Where the same water passes constantly through filters using alum, it is necessary to keep watch of the alkalinity and restore it at times with soda ash.

What is to be done in the way of protecting the pool by rules? It is easier to make than to enforce them, and at

*Paper read at the last annual convention of the New England Water Works Association.

times some failures will occur, but on the whole they are not troublesome. So far as disease transmission is concerned, people who are suffering from anything very serious are not likely to ask admission to the pool, and if they do ask admission, it is the watcher's business to keep them out. I believe that there is less trouble in the matter of damaging the pool from specific diseases than people imagine, due very largely to the fact that people who are suffering therefrom do not care about entering the bath, and certainly they do not care to be caught doing so. We do not ask that a man with a slight cold shall refrain from bathing. In some places they do ask that, but it is carrying the protection of the water pretty far. I have no doubt a man with a mild cold can easily get by without being detected and get to the pool if he wants to go.

Temperature, Color and Turbidity

At what temperature is it best to keep the water? At Rensselaer we keep the pool at 76°, except on the occasion of a swimming match of some kind and then we run it down to 72° merely to put a little "pep" into the men who are performing. Under ordinary conditions if one is going in simply for the pleasure of having a dip, or for learning how to swim, anything short of 74° or 76°, makes it a rather strenuous undertaking. In the summertime, a swim in the open is quite different, and one can stand cold water then very well, but with a pool under cover in the winter time, unless the water is up in the seventies, a bath feels uncomfortably chilly. Of course, a Turkish bath is a different proposition; a cool pool is needed under those circumstances in order to start a reaction from the very high temperature to which the bather has been exposed.

High color or turbidity is unsightly and masks such undesirable floating material as sputum, but beyond that either may be absolutely dangerous. I have in mind what happened at one of our large institutions not many years ago. The pool was very turbid and on draining it, a man who had been missing for some days was found at the bottom. Unless the bottom of a pool can be seen, it is better not to use it. A prominent girls' school has recently closed its pool on account of the turbid character of the water. While it was still in use, whenever a group of girls went in, the teacher had to keep watch all the time to see if somebody was missing. A turbid pool is very dangerous and should not be tolerated. A color or turbidity small enough to be possibly unobjectionable in a drinking glass might be sufficient to prevent the bottom of a pool being seen through a depth of eight or nine feet. Partly in this connection, it may be permitted to add that at one of our universitieis a fatality was occasioned by a student diving into an empty pool at night. Such an accident can, of course, be guarded against by suitable rules controlling admission.

Suction Sweeper Removes Fibre

To remove the sediment which collects at the bottom of the pool we use a sweep at Rensselaer and push everything that settles, onto the top of the outlet grating, whence it is flushed to the sewer by suddenly opening the valve. As I have already said, the grating must be on the bottom rather than on the side to allow of this being done.

In pools used by women, bathing suits are worn, usually colored ones, and the amount of fibre that comes off is vastly more than one would think, and it is most unsightly. I saw a device not very long since in Boston, designed to remove such material. It is best described as a modified carpet sweeper of the suction type, entirely similar to what is ordinarily used for cleaning floor rugs. The handle is about one-and one-quarter inches in diameter, and of course it is hollow, and it is attached to a suction motor by a hose. There is a brush at the bottom and about 18 ins. long and 6 or 8 ins. wide, filled with stiff bristles set along a slot. Upon applying suction the material goes out through the handle and is discharged into the side gutter.

Although chlorination and filtration are the usual means employed for keeping the pool water in proper condition, there are two other ways of securing water improvement—ultra-violet light and ozone—which have been somewhat recently introduced. The University of Illinois formerly used chlorination, but they are now using ultra-violet light, and they speak well of it. As a device it is certainly very attractive in appearance. It may be remembered that the Athletic Club at 59th St. and Sixth Ave., New York, uses it successfully, although with what charge for upkeep I cannot say. The Board of Health of New York City has pretty thoroughly threshed out the question of ozone and has reported favorably on it. The amount of money which is quoted in the Board of Health report is small enough, but the upkeep of an ozone plant is usually considerable. It is a fragile thing. And so is the ultra-violet light outfit a fragile thing. We have one in Troy, used for other purposes, and we have found it to be pretty fragile in our experience.

At Rensselaer we attempt to keep our alum dose about one grain per gallon, but, of course, we do not hope to strike that amount accurately, as we employ self-feeders. It is not as though we had a large plant where we could run in a well-controlled alum solution.

So far as chlorination is concerned, we use a very homely, but we think an efficient, method of application; ordinary bleaching powder is mixed up with water into a cream and distributed directly by hand at the shallow of the pool. In dose we use "bleach" enough to correspond to .6 of a part per million of chlorine, which is the amount legally adopted in California. At Yale they use .3; Northwestern .6, the same as we do; and in some other instances the dose is as high as 1 part per million.

Objections to Dosing

We all realize that there is an immense amount of objection on the part of some bathers to the dosing of a pool. We have had complaint time after time, and it is usually based upon imagination. A bather cannot detect the presence of .6 of a part of chlorine per million. In practical tests we found that there was a suggestion of smell at 1½ parts chlorine per million, but no taste and no action on the eyes whatever. At 2½ parts per million of chlorine there was a faint smell, but there was no taste and there was no action on the eyes. When we ran up to 50 parts per million, of course we got a strong taste and we also got a strong smell, but did not notice any action on the eyes. The bathers have complained of dosing when no dose had been used. I remember that years ago when we were about to turn on the alum at the new filter plant at Elmira, the people tasted the alum four days before we put it in.

With reference to establishing a legal standard for the water of swimming pools, I know of only two states that have made the attempt, California and Florida. California has a pretty liberal standard. They attempt to keep the total count of bacteria below 1,000. At Rensselaer we do better than that. It may be rather more good luck than good management, but we have been running on an average of about 250.

So far as the presence of coli is concerned, we rarely get coli, as our .6 of a part per million of chlorine every week seems to control their growth. California allows one bacillus coli communis per cubic centimeter.

The preliminary showers should not be too cold and the soap used should be liquid. Many people dread a cold shower although they do not object to a cool plunge, consequently, unless arrangements are made to take the chill off the shower water, the actual washing accomplished by it will be rather sketchy.

Treatment With Copper Sulphate

Pools that are built in the open without protection from direct sunlight, will probably be troubled with growths of algæ, especially if they be filled with ground water. Copper sulphate is the natural remedy in such a case and the amount required, which is very minute, is best determined by trial. Considerable stress is sometimes laid upon the advantages of direct sunlight in those unusual cases of such indoor pools as possess it, but the gain is offset, at least in part, by liability to algal growths. In such instances copper sulphate is again useful, but the need for complicated apparatus to administer the dose is unnecessary. Plants supplied with such dosing outfits seldom or never employ them.

Report on Water Powers of British Columbia

Volume of More Than 650 Pages, by Arthur V. White, Published by the Commission of Conservation—Thoroughly Covers Water Legislation, Meteorological and Topographical Data, Surveys and Maps, Stream Flow Data, Bench Marks, Power Sites, Present and Proposed Developments, Electrical Inspection and Bibliography

COMPRISING 610 pages (6¾ by 9¾ ins.) of text, 36 pages of half-tone illustrations, 10 pages of line diagrams, 3 maps and 24 pages of index, the volume, "Water Powers of British Columbia," just issued by the Commission of Conservation, forms a substantial and noteworthy contribution to Canadian civil engineering literature. The volume was written by Arthur V. White, consulting engineer to the Commission, assisted by Charles J. Vick.

The field work necessary to secure the data for the volume was started in 1911, with the assistance of the British Columbia government, but circumstances connected with the war delayed the publication of the report. It is now ready for gratuitous distribution, however; engineers and others interested in the subject should apply at once for copies, as the edition is limited. A small number of copies have been bound in cloth, but the greater portion of the edition is paper-bound.

The book is divided into 18 chapters, as follows:—

1. General introductory survey (30 pages).
2. Water power data (16 pages).
3. Historical survey of water legislation in British Columbia, with chronological key (66 pages).
4. Certificates of approval; orders in council; rules, regulations and fees (18 pages).
5. Electrical inspection by province of British Columbia; table of power plants (10 pages).
6. Electrical inspection by Dominion of Canada; exportation of electricity (9 pages).
7. Power developments in British Columbia; brief description of the chief developed water powers from the physical standpoint; some proposed power developments; brief reference to a few undeveloped water powers which have been specially investigated (27 pages).
8. Surveys and maps of British Columbia, including a reference to range of tidal levels (15 pages).
9. General topography of British Columbia (5 pages).
10. Columbia river and tributaries; topography; power site tables (32 pages).
11. Fraser river and tributaries; topography; power site tables (29 pages).
12. Vancouver Island; topography; power site tables (9 pages).
13. Mainland Pacific coast; topography; power site tables (31 pages).
14. Mackenzie river and tributaries; topography; power site tables (8 pages).
15. Stream flow data; gauging stations in British Columbia; historical reference to inauguration of stream flow study in province; description of stream flow data included in this volume; index to published stream flow data; tables of stream flow data; miscellaneous discharge measurements (158 pages).
16. Stream flow data; certain gauging stations in United States; reference to gathering of stream flow data in United States; index to published stream flow data on international streams; tables of stream flow data (22 pages).
17. Diagrams showing the distribution of precipitation, temperature and run-off in British Columbia; explanatory statement (17 pages).
18. Meteorological data; introductory statement; list of precipitation stations in British Columbia and selected stations in Alberta and Yukon; precipitation records for stations in British Columbia and selected stations in Alberta and Yukon; list of selected precipitation stations in United States on international watersheds or adjacent to British Columbia; monthly and annual mean precipitation at selected stations in United States; temperature records for selected stations in British Columbia; monthly and annual mean temperature at selected stations in United States (85 pages).

Appendices: (a) Hydraulic conversion tables and convenient equivalents, with statement respecting the "miner's inch" (10 pages); (b) list of certain bench marks on Vancouver Island and Pacific mainland coasts (4 pages); (c) bibliography (19 pages); and (d) index (24 pages).

A two-page, two-color physiographic map of British Columbia is bound in with Chapter 9, "General Topography of British Columbia," while two large three-color maps, "Water Powers in British Columbia," and "Precipitation Stations in British Columbia and Portions of Yukon, Alberta and United States," are folded and inserted in a pocket in the cover. The various power sites and precipitation stations indicated on the maps are so numbered as to afford rapid and easy reference from the maps to the corresponding description in the text, or vice versa.

STREAM ON PRINCESS ROYAL ISLAND

A typical steep descent from lake in "hanging valley," as frequently found along the fjords of the British Columbia coast.

1. Introductory Survey

Chapter 1 reviews the general objects of the report and discusses various phases of the subject under such headings as the influence of forests upon run-off; the relation of water to agriculture; the relation of water power to irrigation; the interdependence between water power and navigation; the serious interrelationship between inland fisheries and the dams and other structures required for water-power development; the relation of the inland waters to mining and to the tourist traffic; the possible effect upon international relationships, etc. Concluding this discussion, the author summarizes it as follows:—

"First, we have observed that precipitation is the prime source of inland water supply, and that not only water power, but such other interests as domestic and municipal water supply, agriculture, irrigation, navigation, fisheries, mining and riparian rights, are all dependent upon the same source. Consequently, water should not be allotted for power development without due recognition to the just demands of other interests having claims upon our inland waters viewed broadly as a natural resource.

"Second, run-off, manifested in the form of stream flow, is intimately associated with the character of the ground

upon which precipitation falls, and, consequently, care should be taken to conserve vegetal cover; more especially is this necessary for rocky areas which have but scanty soil covering.

"Third, subsoil waters are by no means inexhaustible. Plant growth is dependent upon having available an adequate amount of soil moisture. Nothing should be done to deplete, unduly, the ground-water storage. Effective legislation and administration should be provided governing the tapping of underground water supplies.

"Fourth, the use of water for irrigation tends materially to increase the permanent settlement of the country. Consequently, in most instances, when irrigation requirements and power requirements conflict, the former are entitled to precedence. Hydro-electric power developed on somewhat distant streams may, by means of high tension transmission, be used for pumping water supplies where such are not available by gravity, and may thus facilitate irrigation development.

"Fifth, not infrequently navigation interests are regarded as of much greater importance than power development. Any works contemplated for the improvement of navigation should be considered in their relationship to river systems as a whole. Expenditures should be carefully watched and precautions taken to ensure that improvements, so called, are not undertaken ostensibly for navigation, when in reality they are sought for the sake of such water-power benefits as may incidentally be developed thereby.

"Sixth, the fishing industry in British Columbia is one which demands that the best possible methods be used for its conservation. Provision requires to be made for the upward migration of adult salmon for spawning purposes, and the downward passage of the young fish to the sea. Obstructions, such as dams, rock slides, log jams, etc., may have a disastrous effect upon this industry. Fishways should be provided. The whole question of fishways requires thorough investigation. Other fish besides salmon require conservation. It is not established that satisfactory means have been devised by which fish may successfully ascend over high dams—even over dams which do not exceed twenty to thirty feet in height.

"Seventh, the development of the mining industry during recent years has resulted largely through electrical energy being available through the development of provincial water powers, and the future offers bright prospects for the further application of hydro-electric power to the various branches of this industry.

"Eighth, the pollution of inland waters must be jealously guarded against. Mining, factory and industrial wastes and sewage must not be permitted to foul inland waters. Debris and other waste resulting from logging operations are apt to cause serious log jams, which are a menace to public highways, bridges and also to power development.

"Ninth, the tourist traffic is a valuable provincial asset, not only because of the money actually spent by travellers, but because of the opportunity afforded of drawing attention to the various natural resources of the province. Consequently, every reasonable care should be taken to guard against the spoiling of shorelands through submergence; and further, care should be exercised in the design and construction of power works, making them, where possible monize with the general natural features of their surroundings.

"Tenth, in connection with the use of boundary waters, problems, from time to time, may arise necessitating consideration by the International Joint Commission. In this connection, therefore, it is especially desirable that physical data appertaining to such waters should be so collected as to be available for use in connection with such problems as may arise respecting waters which are classed in the Boundary Waters Treaty as boundary waters."

2. Water-Power Data

Chapter 2 states that "one of the chief objects in securing and publishing data respecting water powers, is to enable the owners of rights to determine the possibilities and limitations of their powers and thus arrive at sound judgment respecting their possible uses and value. Another object is to enable prospective promoters to learn the general possibilities of various powers without the necessity of making costly independent, preliminary surveys. Certainly, if the Crown be the owner of water powers, it is of the utmost importance that it be informed beforehand upon essential facts connected with its water resources."

This chapter cautions investors against proceeding with developments without sufficient knowledge of physical and economic governing factors. The author cites a number of cases in the United States where financial losses have resulted from power developments. The summary of this chapter is as follows:—

"First—Governments have been bestowing increasing attention upon the investigation of inland water resources and, during recent years, Canada has made great advancement in this work. Such work is essential in order to acquaint interested parties with the possibilities of the powers with which they may be dealing.

"Second—A number of factors, such as character of use, uniformity of flow, the making of but partial development in a manner prejudicial to future complete utilization, failure rightly to differentiate between primary power and secondary power, etc., have been noted and attention drawn to the necessity for reckoning with such factors.

"Third—Hydrometric data extending over a sufficient period of time should be available, and conclusions involving important procedure should not be predicated upon scattered and insufficient records. Topographic maps should also be available.

"Fourth—Those interested from the standpoint of the investor may, by the expenditure of ordinary effort, place themselves in a position, independently, to check and form a judgment respecting some of the basic engineering factors involved in any power project under consideration.

"Fifth—Failure rightly to assemble or interpret essential physical data, has been responsible for many serious failures, and has resulted in great financial loss.

"Sixth—No reliance should be placed upon general statements setting forth the existence of vast undeveloped water powers. The total amount of water power capable of economic development is much less than popularly assumed and most of the valuable sites are already under development or control by various interests. Attention has been directed to the concentration of control of water powers as proceeding rapidly in the United States, and the need has been pointed out that those interested in the conservation of our water powers should be alert to see that the same menace to public welfare does not operate in Canada. Much of this concentration of control has taken place during a time when general statements representing the existence of large reserves of potential water power were being presented to the attention of the public and were receiving general acceptance.

"Seventh—The importance of storage has been pointed out, and the possibilities of storage causing damage to riparian owners has been emphasized. Government provision for a flowage easement along the shores of lakes and rivers, would to some extent protect settlers against loss, and would protect the government itself against claims for damage by overflow."

3. Water Legislation

British Columbia possesses one of the most comprehensive water codes in the world. This code has been a gradual evolution from the mining regulations, growing out of the first mining activities in the province. The whole water law of the province is reviewed in Chapter 3, where more than 80 separate enactments have been carefully analysed in order to show their contribution to the water code as it today exists.

The present law deals with the utilization of water for mining, municipal and industrial purposes; irrigation; lumbering operations; water power; and many other purposes. British Columbia is the owner of the water in its inland streams and lakes. This water is leased, under certain conditions of rental, etc., for a term of years. The present provincial Water Act is a voluminous document of some 300 sections. It is a noteworthy measure and vests in the gov-

ernment, by statutory laws, the absolute control of the inland waters of the province. It is not possible to obtain an adequate understanding of the water laws of British Columbia as they are at present, without knowledge of the various individual parts of separate Acts which constitute component parts of the consolidated laws. To supply such knowledge is the aim of this chapter on water legislation. The author reviews the various governmental water measures, so far as possible, in chronological order.

4. Certificates of Approval

In Chapter 4 further information is given regarding the procedure for obtaining a water license, certificates of approval, fees, the making of surveys, etc. A 5-page table gives a list of the certificates of approval and orders-in-council that have been issued to date relating to the diversion of water for power and other purposes. This table gives the name of the grantee in each case, the name of the stream affected, the date of approval, the date and page of publication in the British Columbia Gazette, and remarks indicating the nature of the undertaking that was approved.

5. Electrical Inspection by Province

In Chapter 5 the author shows what steps have been taken to protect the public from accidents arising from the increased use of electrical energy, how companies are protected from unjust claims made by injured parties, and how companies are protected from undue pressure by municipalities. The chapter concludes with a list of the principal equipments of power developments in British Columbia which come within the jurisdiction of the Electrical Energy Inspection Act.

6. Electrical Inspection by Dominion

Chapter 6 deals with the subject of electrical inspection by the Domonion of Canada, chiefly in its bearing upon the exportation of electricity. Commencing with the British North America Act of 1867, the author traces the history of events leading up to the Electrical Inspection Act and to the Electricity and Fluid Exportation Act. There is supplied a list of electric light and power installations in British Columbia falling under Dominion jurisdiction.

RAPIDS ON THOMLINSON CREEK, A TRIBUTARY OF THE TOBA RIVER
A typical coast stream, descending over 600 ft. in 4 miles.

7. Power Developments

In addition to the table of "Power Plants in British Columbia," given in Chapter 5, there are specially described in Chapter 7 twenty of the more important hydraulic developments in the province.

There is in all about 300,000 h.p. at present developed by water power in British Columbia. The aggregate capacity of the installed prime movers is also about this amount, of which 152,000 h.p., or about 50%, is installed at the various plants of the British Columbia Electric Railway Co. and the Western Power Co., to supply the needs of Vancouver and Victoria and surrounding districts, including various municipalities in the Fraser river delta.

Another important power-using district is that supplied chiefly by the two plants of the West Kootenay Power & Light Co. at the Bonnington falls on the Kootenay river —namely, the boundary district lying to the south and west of Nelson. The total hydraulic installation in this district is about 50,000 h.p., used chiefly for the mining industry.

Of the larger developments for industrial purposes, about 50,000 h.p. is installed for pulp and paper manufacture, and approximately 40,000 h.p. for mining, in addition to the 40,000 h.p. developed by the West Kootenay Power and Light Co. and used chiefly for mining and smelting purposes.

It is interesting to note that a large development of water power has been found profitable at the mines of the Canadian Collieries, Ltd., on Vancouver Island, where coal is available at pit-head cost. There are about twenty water-

TETACHUCK FALLS, BELOW OUTLET OF TETACHUCK LAKE
This picturesque fall on the upper waters of the Nechako River is typical of undeveloped power sites in the interior of British Columbia.

power developments in British Columbia, in which the installed capacity in each case exceeds 1,000 h.p. These are as follows:—

PRINCIPAL WATER-POWER DEVELOPMENTS IN BRITISH COLUMBIA

Development.	Installed h.p.	
British Columbia Electric Railway Co.		
Coquitlam-Buntzen power house No. 1	43,500	
" " " " " 2	40,500	
Esquimalt reservoir plant	4,200	
Jordan river plant	25,000	
		113,200
West Kootenay Power & Light Co.		
Lower Bonnington falls	4,050	
Upper " "	34,000	
Cascade plant on Kettle river	3,900	
		41,950
Western Power Co. of Canada, Stave falls plant		39,000
Powell River Co., plant on Powell river		24,000
Pacific Mills, Ltd., plant at Ocean falls		21,100
Britannia Mining & Smelting Co., plants at Britannia Beach		12,640
Canadian Collieries (Dunsmuir), Ltd., plant on Puntledge river		12,000
Granby Consolidated Mining, Smelting & Power Co., plant on Falls creek		6,600
Whalen Pulp and Paper Mills, Ltd.		
Plants on Mill and Cedar creeks	4,000	
Plant at Swanson Bay	2,500	
		6,500
Nelson City, Upper Bonnington falls		3,400
Hedley Gold Mining Co., plants on Hedley creek and Similkameen river		2,600
Revelstoke City, plant on Illecillewaet river		2,550
Kamloops City, plant on Barriere river		2,400
Prince Rupert City, plant at Woodworth lake		1,650
Surf Inlet Power Co., plant at Surf Inlet, Princess Royal Island		1,260
Granby Mining, Smelting & Power Co., plant on Granby river		1,040
		291,890

In this chapter are also brief descriptions of a few of the large undeveloped powers which have been the subject of special investigation and for which developments are proposed. These include the following:—

Diversion of Bridge river to Seton lake, 1,200 ft. head, 100,000 h.p.; Campbell river, head 125 to 450 ft., depending upon scheme adopted, 100,000 h.p.; Shuswap river, 130 ft. head, 12,000 h.p.; Jones lake diversion to Fraser river, 1,800 ft. head, 25,000 h.p.; Indian (Mesliloet) river, heads about 1,900 ft. and 450 ft. (group development), about 10,000 h.p.; Falls river, 245 ft. head, 16,000 h.p.; Khatada River, 350 ft. head, 10,500 h.p.

8. Surveys and Maps

Chapter 8 is devoted to surveys and maps. To the engineer who requires to assemble data basic to the consideration of any water-power project in British Columbia, it will be a grateful aid to find at hand this classified analysis of the various surveys and maps relating to the province. There is a complete list of maps relating to British Columbia published by the Geological Survey of Canada, the Department of the Interior, the British Columbia Department of Lands and the Admiralty. In almost every case there are given the number of the map, the title, the scale, the price if any, the year of issue, and the approximate size of the map.

9—14. Topography and Power-Site Tables

Beginning in 1911 in the southerly part of the province, the Commission of Conservation inaugurated its reconnaissance water-power survey of British Columbia. In addition to the results obtained by direct field operations, information respecting water-power possibilities of the provincial streams was gathered from exploratory and other reports, from individuals, from corporations and from governmental sources. This information has been assembled and condensed into tabulated power-site tables, which are set forth, together with explanatory notes and topographical information, in Chapters 9 to 14, inclusive.

For the purpose of convenient reference, the province was divided into five districts corresponding in the main to the chief drainage areas. These are: (1) Columbia river and tributaries; (2) Fraser river and tributaries; (3) Vancouver Island; (4) mainland Pacific coast and adjacent islands except Vancouver Island; and (5) tributaries to the Mackenzie river.

The general topography of the whole province is broadly and clearly described in Chapter 9. With the aid of the physiographic map that accompanies that chapter, one obtains a comprehensive understanding of the chief topographical features, especially of the various mountain systems which modify the climate, and influence precipitation and stream flow. The power possibilities of the five districts above mentioned are then dealt with in order, a chapter being devoted to each district. In each chapter the power-site tables are introduced by a description of the topography of the district, supplemented where necessary by brief notes descriptive of the chief tributaries and their respective watersheds.

Preceding the first group of power-site tables is a description which explains their scope and limitations. In the tables the streams are tabulated in ascending order. The power sites are numbered, those on the main streams being first given, followed by the tributaries taken in their respective order as each main stream is ascended. This arrangement permits easy reference both from the tables to the index map and from the map to the tables.

In the tables one finds the name of the stream and site; the watershed area (in square miles) as derived from the latest map or estimated from special survey data; the head (in feet); the estimated horsepower; and remarks respecting the characteristics of the site, such as the character of the fall, gradient of the rapids, the nature of the stream bed and banks, the possibilities for storage, the practicability of dam construction, etc.

The estimates of horsepower are said to be conservative. They are, for the most part, on a 24-hour basis at 80% efficiency and for an ordinary low-water month. Where storage sites are definitely known, weight has been given to this possibility in making the estimates. It is pointed out, however, that owing to lack of precise information the storage possibilities yet to be discovered will be an important factor in increasing the power.

In round numbers, the horsepower totals derivable from the various estimates presented in the power-site tables are as follows:—

		24-hr. h.p.
1.	Columbia river and tributaries north of the international boundary. This comprises the portion of the province lying between its eastern boundary and the watershed of the Fraser river	610,000
2.	Fraser river and tributaries. This includes practically the entire area of the great interior plateau	740,000
3.	Vancouver Island	270,000
4.	Mainland Pacific Coast and adjacent islands, except Vancouver Island. This includes all the rivers north of the Fraser which drain into the Pacific	630,000
5.	Mackenzie river tributaries. A rough estimate made for inclusion in this summary	250,000
	Total	2,500,000

Statements made show that there are about 500,000 h.p. which, at least for many years to come, can hardly be economically developed because interference with the fishing industry or the proximity of railways renders development impracticable. There are also some other qualifying statements applicable to portions of the power tables, but in round figures the grand total of estimated 24-hr. power, in-

cluding an allowance for storage possibilities, has been placed at about 3,000,000 h.p.

With regard to this total estimated horsepower, it is emphasized that "grand totals purporting to represent horsepower possibilities for large sections of a country, are apt to be very misleading. They are especially misleading when used to make comparisons with other totals when, as a matter of fact, no real basis for comparison has been established. The unique character of many of the water-power possibilities of British Columbia, with its exceptional physical features, such as mountain systems, glaciers, snowfields, and widely variant precipitation, necessarily makes it difficult to effect comparisons between the total water-power possibilities of this province and those of other areas differing markedly in physical characteristics."

The engineers who chiefly assisted in the field work from which the above-mentioned data were compiled were G. H. Ferguson, C. J. Vick, D. C. Jennings, C. C. Lyall, A. W. Campbell, L. G. Mills, T. G. Bird, R. Westover, W. A. Wand, F. R. Macdonald, B. Corbould, B. N. Simpson and C. C. Cowan; also A. J. McPherson, who was attached to one of the field parties in 1913 as representative of the Provincial Water Rights Branch. On account of the topography of the province and the difficulty of reaching some portions of it, the work of many of the field engineers was arduous and hazardous and evidently also required a high degree of ability and judgment.

15—18. Stream Flow and Meteorological Data

Stream flow and meteorological data occupy Chapters 15 to 18 inclusive. This collection of records furnishes the engineer with data which would take him much time and effort to assemble independently. Much of the stream flow data is gathered from the Water Resources Papers issued by the Water Power Branch of the Department of the Interior, and due credit is given to that department for same, but other sources of information have also been used and receive credit, many of the records having not hitherto been published.

Chapter 15 contains the stream flow data available for British Columbia, while Chapter 16 supplies similar data for a number of stations in the neighboring states of Washington, Idaho and Montana, on such streams as the Columbia, Pend-d'Oreille, Kootenay and other rivers of an international character. The records have apparently been selected with special reference to their serviceability for water-power development, as some streams serviceable only for irrigation purposes have not been included.

The records are arranged in alphabetical order, and each one is introduced with a brief description of characteristics appertaining to it. To assist in quickly turning to the more detailed records, which include gauge heights, etc., there is an index to stream flow data elsewhere published.

In the meteorological data there is very complete tabulation of precipitation records for all stations in British Columbia, including monthly and annual total precipitation, and, where length of record warrants, the mean monthly and mean annual precipitation (Chapter 18). A summary of snowfall record is also given. Meteorological data is also supplied from portions of Alberta, Yukon, Alaska, Washington, Idaho and Montana, where such data is specially pertinent to some of the watersheds of British Columbia.

In order to convey an understanding of the general trend of meteorological and hydrological phenomena as revealed by the precipitation, temperature and stream flow records, a number of special diagrams (Chapter 17) summarize these data.

An inspection of these diagrams reveals the manner in which the outstanding physical features of British Columbia modify the climate and precipitation in various parts of the province. Due to the great mountain barrier formed by the coast mountains, British Columbia is climatically divided broadly into two main divisions: The Pacific littoral, west of the summit of this range; and the interior, to the east. The other great mountain systems, the Columbia system and the Rocky mountains, modify the climate of the interior and to some extent reproduce the contrasting phenomena as found on the western and eastern side of the coast range in so far as precipitation is concerned. It is, however, the coast mountains that constitute the dominating influence and that control the climate of the interior. The diagrams demonstrate that the Pacific littoral is a region of great precipitation, especially in the winter months. It is characterized, moreover, by a mild and equitable climate, while the run-off from the streams is heavy; and where fed by glaciers, the run-off is well distributed throughout the year.

In the interior the precipitation, except on the western slopes of the eastern mountain systems, is relatively small, the yearly temperature has a much greater range, and the run-off of the streams exhibit different phenomena. All streams in the interior reach their maximum discharge for the year in the earlier summer months and have lowest water conditions in January and February. On the coast the low water is usually at the end of the summer, in August and September, and the maximum floods obtain at the time of the autumn rains in November, although a second peak flood occurs in the early summer on those streams fed in part from glaciers and elevated snowfields.

The influence upon run-off of latitude, elevation, storage and other factors is also shown by the diagrams.

Bibliography

The volume concludes with handy hydraulic conversion tables, a list of certain bench marks, and an extensive bibliography which will be valuable in studies concerning the development of agricultural areas, mining industry, timber industry and fisheries as well as of other provincial resources. In greater or less degree these various branches of activity have been linked up with and are dependent upon the beneficial utilization of inland waters.

About 230 publications are described, some having special explanatory notes. They are classified under the following broad subject headings:—(1) General reference works; (2) Guides, handbooks and other publications giving descriptive information and historical data relating to various natural resources of the province; (3) government and other publications containing descriptions of the physical characteristics of various watersheds; (4) travel and exploration, mountaineering and other sport; (5) works of historical interest, including northwest coast voyages, Hudson Bay Co. affairs, international waters, boundaries and treaties.

In the case of references to the publications of such organizations as the Geological Survey of Canada, the Royal Society of Canada, the Royal Geographical Society of Great Britain, etc., the bibliography quotes "chapter and verse" for such data as have direct bearing upon the natural resources of British Columbia.

The Turbine Equipment Co., Ltd., have moved their offices to the Dack Bldg., 73 King St. W., Toronto. R. M. Austin, manager of the company, is the Canadian representative for Ontario and Western Canada of the De Laval Steam Turbine Co., of Trenton, N.J.

The following Canadians have been invited by the General Electric Co. to inspect a new 265-ton, 3,000-volt, direct-current, gearless electric passenger locomotive which the company has constructed for the Chicago, Milwaukee & St. Paul Ry., and which is now being exhibited at Erie, Pa.: J. A. Shaw and W. H. Winterford, of the Canadian Pacific Railway; C. B. Walker and C. P. Price, of the Canadian National Railways; J. G. Baukat and W. G. Hewson, of the Hydro-Electric Power Commission of Ontario; S. B. Clement, chief engineer, Temiskaming and Northern Ontario Railway; and representatives of the Canadian General Electric Co., Ltd. At the company's test track at Erie, Pa., a speed of 65 mi. per hr. has been obtained and the tests indicate that the locomotive will operate at much higher speed, but that is the limit permissible on the test track. For continuous operation the locomotive is designed to exert 42,000 lbs. tractive effort at a speed of 25 mi. per hr.

WATER POWERS OF BRITISH COLUMBIA

IN 1910 the Commission of Conservation undertook an inventory of the water power resources of Canada. As a result, in 1911 the Commission's first report on this subject was printed, "The Water Powers of Canada," covering in summary form the information then available for Ontario, Quebec, and the Maritime Provinces. In 1916 a second volume appeared, "The Water Powers of Manitoba, Saskatchewan and Alberta." The report on British Columbia, which was being compiled under the direction of Arthur V White, consulting engineer to the Commission, was delayed by circumstances owing to the war, and has just been issued, completing the Commission's series of reports on this great natural resource.

The volume just issued is more than a report on the water powers of British Columbia; it is also a valuable textbook and an interesting account of all the factors that must be considered in connection with the utilization of water resources. It is written in Mr. White's usual forceful, lucid and logical style, and covers thoroughly all cognate phases of the subject under investigation. Not only is it comprehensive but also compact, no space being wasted despite the large number of pages in the volume. In illustrations, topography and general arrangement, the volume leaves nothing to be desired, and both text and tables bear evidence of painstaking care.

Advantage was sensibly taken by Mr. White of all existing information upon the subject, and of all contemporaneous work done by federal and provincial departments as well as by private companies. Naturally, therefore, some of the data contained in the present report is to be found in other previous publications, notably (so far as the stream-flow data are concerned) in the Water Resources papers of the Water Power Branch, Department of the Interior, but full credit is given to all such sources of information. By making use of others' records wherever they could be obtained and were deemed reliable, Mr. White avoided duplication of effort and saved money for the Commission and for the province, which co-operated in financing the report. Nowhere else has so much data pertinent to the water resources of British Columbia been brought within the compass of one book and so well summarized and correlated. In gathering his own field data, Mr. White had several parties of engineers engaged for a considerable period, and these men had many obstacles to overcome in performing their work, owing to the rough and mountainous sections covered.

The paucity of information concerning British Columbia's water powers existing when the Commission undertook its inventory, is well expressed in the British Columbia Year Book for 1911, which states: "Speaking generally, there is no field of economic interest in connection with the exploitation of the provincial resources respecting which there is less known than the extent to which our water powers may be rendered available." Any person reviewing Mr. White's report will readily perceive how radically different is the present status of British Columbia with regard to knowledge of water resources as contrasted with the status in 1911.

The engineer who has to deal with water power projects will be gratified to find such a complete assemblage of physical data as are presented in tabular form in various parts of the report. These include tables giving the estimated possibilities of water power sites throughout the province, which lists are based chiefly upon results obtained from the special field investigations conducted by the Commission of Conservation. There are also extensive digests of stream-flow, meteorological and other hydrometric records.

The report estimates that a total of 3,000,000 h.p. (24-hour power) is available in British Columbia, and states that "the conditions affecting powers in the province are unique, and do not closely correspond to those existent in other portions of Canada. This is especially true of the mainland Pacific coast. One cannot but be impressed with the fact that coastal water powers in British Columbia, which to the casual observer appear to be of comparatively small amount, nevertheless, may, when economically and fully developed, yield several-fold the estimate of power if appraised upon the same basis as similar streams in Eastern Canada. Glaciers, snow-fields, and heavy rainfall abound, and, with many storage possibilities, constitute unique factors which contribute to enhance the values of powers."

A study of the "Remarks" column of the power-site tables, and of comments throughout the report, reveals the diversified uses to which hydro-electric power in British Columbia has already been applied. The report is replete with references to the extensive and varied natural resources of the province. When one considers the mining, agricultural, lumbering, fishing, navigation and other activities, it is evident how great are the future possibilities for increased utilization and conservation of British Columbia's inland waters, and especially of the power derivable therefrom. In such development *The Canadian Engineer* believes that Mr. White's report will not disappoint the aim of the Commission of Conservation in providing a valuable compendium of data upon this subject.

INTER-PROFESSIONAL CONFERENCE AT DETROIT

WITH the purpose of bringing together the professional men of the United States in order to plan more effective relations and to act together on matters pertaining to the public good, an Inter-professional Conference is being called to meet in Detroit November 28th and 29th. The conference was suggested by the Post-War Committee of the American Institute of Architects, which was established to study the new obligations thrust upon the architectural profession by the war.

It is the hope of those fostering the movement to perpetuate to an appreciable degree the enthusiasm of the war-time service rendered to the public by the professional men. The subjects which are to be taken under consideration have been classified under three heads:—The functions and inter-

relations of professional organizations; relations of professions to the public; and educational obligations of the professions. Representatives of the medical, legal, and engineering professions have accepted membership on the organizing committee.

HYDRO-ELECTRIC POWER DEVELOPMENT AT HIGH FALLS

(Continued from page 454)

ment, of which Henry G. Acres is the hydraulic engineer; Thos. H. Hogg, assistant hydraulic engineer; and Max V. Sauer, designing engineer. E. T. Brandon is the electrical engineer of the Commission; and Arthur H. Hull, assistant electrical engineer. The resident engineer at High Falls is A. L. Malcolm. E. V. Trimble, engineer of the Commission's construction department, is represented on the work by E. F. Lynn.

SWIMMING POOL MANAGEMENT

(Continued from page 460)

Referring again to outdoor pools, it is unfortunate that some cities, even large ones, are not sufficiently careful to select suitable sites for their public baths. When a city goes so far as to fence off and equip some portion of a river or bay, setting aside the same as a public bathing place, the bathers have a right to assume that the site has been selected with care and that the water is hygienically safe, but sometimes the assumption is distinctly risky. In one instance a great metropolitan sewer emptied on the upstream side of a public bath (now closed), and so near that when the sewage was colored by a red dye, the bathers were startled by the bloodlike tint of the bath water.

It is vain to hope that high bacterial counts and the presence of "gas formers" can always be avoided. The human animal is not quite clean enough to insure that, but, nevertheless, it is entirely feasible so to run a public swimming pool as to keep its appearance attractive and its use within what may be termed "proper and reasonable risk."

PERSONALS

F. S. Lazier, resident engineer of Section 2, Welland Canal, has been elected president of the Engineers' Club of Thorold.

Maj. J. C. Johnstone, Maj. J. R. Cosgrove, Frank H. Allwood and J. E. Milne are being considered by the Saanich, B.C., council for the position of municipal engineer.

G. H. Duggan, president of the Dominion Bridge Co., Ltd., Montreal, has been elected chairman of the newly appointed Quebec Division of the Canadian Manufacturers' Association.

Fred J. Matthews has opened an office at 33 Richmond St. W., Toronto, as sales representative of the H. H. Robertson Co., Ltd., of Sarnia, Ont., manufacturers of building products and highway materials.

Brig.-Gen. C. H. Mitchell and Prof. J. C. McLennan received the honorary degree, Doctor of Laws, last week at the University of Toronto, in recognition of their distinguished services during the war.

J. L. Thomas, formerly sales manager of the building supply department of the N. J. Dinnen Co., Winnipeg, is president and general manager of the recently organized Manitoba Clay & Building Supplies Co., Winnipeg.

Col. Alex. P. Deroche, of Napanee, Ont., has resigned his commission in the Canadian Engineers to accept appointment as general manager of Bate, McMahon & Co., contractors, Ottawa, succeeding the late Col. R. S. Low. Col. Deroche is a civil engineer and a graduate of the Royal Military College, Kingston.

William Worth Pearse, city architect of Toronto, has resigned in order to accept appointment as business administrator of the Toronto Board of Education at a salary of $8,000 per annum. Mr. Pearse was born December 4th, 1872, in Toronto and was educated at the Toronto public schools and Jarvis St. Collegiate. He studied architecture for 3 years under Kennedy & Holland, and for about 2½ years under Wm. G. Storm, who was architect for University of Toronto and other large buildings. Mr. Pearse passed the final examinations of the Ontario Association of Architects and then went to New York to study civil engineering, taking the degree of B. Sc., and later a 3-year post-graduate course in structural engineering. While in New York he was connected with a number of engineering companies and architects of more or less prominence, among whom were the American Bridge Co.; Levering & Garrigues, construction engineers; and the Radley Steel Construction Co., of which Mr. Pearse became chief engineer and vice-president, in which position he was connected with the construction of a number of important buildings in New York. In May, 1914, Mr. Pearse returned to Toronto to accept the position of city architect at a salary of $5,000 per annum. During his 5½-years' stay in the city hall, he revised the building by-law, the printing of which has just been completed. Particular attention was given in its preparation to flat-slab concrete construction and to brick work, and much research work was done and many tests were made before writing some portions of the new by-law. Mr. Pearse is an associate member of the American Society of Civil Engineers and a member of the Ontario Association of Architects.

M. B. Weeks, formerly Director of Surveys of Saskatchewan, has been appointed Director of Town Planning, and W. A. Begg, formerly townsite engineer for the Department of Highways of that province, has been appointed Town Planning Engineer by the Dominion government.

D. H. McDougall and Thomas Cantley, who are respectively president and chairman of the board of directors of the Nova Scotia Steel & Coal Co., Ltd., are on a tour of the coal mines and steel plants in England, France and Italy, and of the iron mines in Spain, Norway and Sweden.

George B. Mitchell, who is well known in Montreal, where he resided a number of years, and who for the past eighteen months has been construction engineer with the Foundation Company at Port Huron, expects to sail this month for Peru in the interests of the Foundation Company.

Col. H. R. Lordly, consulting engineer, Montreal, has been awarded the McGraw Fellowship in civil engineering by Cornell University. Col. Lordly is a Cornell graduate and a Fuertes gold medal winner. He is now at Ithaca doing research work. He expects to receive the degree of Master of Civil Engineering next June.

Lt.-Col. W. G. MacKendrick, president of the Warren Bituminous Paving Co. of Ontario, was one of a number of veterans who were decorated at the Parliament Buildings, Toronto, last week by the Prince of Wales. Col. MacKendrick received the Legion d'Honneur. During the war he was Director of Roads for the Fifth British Army.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

ADDITIONAL TENDERS PENDING

Not Including Those Reported in This Issue

Further information may be had from the issues of *The Canadian Engineer*, to which reference is made.

PLACE OF WORK	TENDERS CLOSE	ISSUE OF	PAGE
Baintree, Alta., erection of frame school building	Nov. 18.	Nov. 6.	48
Montreal, Que., briquetting machinery	Dec. 14.	Nov. 6.	54
St. Clements, B.C., bridge	Nov. 19.	Oct. 16.	48

BRIDGES, ROADS AND STREETS

Dundas, Ont.—The ratepayers passed a by-law to provide $3,500 for the construction of a new bridge over the creek at Head St. Engineer, J. W. Tyrrell, Hamilton.

Enderby, Alta.—Tenders will be received by the Honorable the Minister of Public Works up to noon of Wednesday, November 19th, 1919, for the erection and completion of a highway bridge over the Shuswap River at Enderby, B.C. Plans and specifications may be seen or obtained at the Department of Public Works, Parliament Buildings, Victoria, B.C.; at the offices of the district engineer, Court House, Vancouver, B.C., and at the offices of the assistant district engineer, Vernon, B.C.

Erickson, B.C.—Tenders will be received by the Hon. the Minister of Public Works, Parliament Buildings, Victoria, B.C., up to noon of Tuesday, November 25th, 1919, for the erection of a highway bridge over the Goat River, near Erickson. Plans and specifications may be seen at the Department of Public Works, Parliament Buildings, Victoria, B.C.; at the office of the District Engineer, Court House, Vancouver, B.C., and the office of the District Engineer, Nelson,, B.C.

Fredericton, N.B.—Tenders are being called by the Provincial Department of Public Works for flooring for the highway bridge at Andover, Victoria County, and rebuilding the Lucas bridge, parish of Chipman, Queens County.

Fredericton, N.B.—The Canadian National Railway authorities have had plans and specifications prepared for the erection next spring of a new bridge near here. Tenders will be called.

Galt, Ont.—Ald. S. J. McLane, chairman of the Board of Works, introduced by-laws at a recent meeting of the city council, providing for the construction of cement sidewalk on the south side of Oxford St., from Bond St. to Dundas St., and a sidewalk on the west side of Forest Rd., from Cedar St. to Waterloo Ave. Ald. McLane will also introduce a by-law to construct a sidewalk on Hobson St.

Kitchener, Ont.—At a special meeting of the Waterloo county council held recently, by-laws were passed establishing the township road between Elmira and Floradale as a county road. This road will be a continuation of the provincial county road from Elmira to Hamilton.

Niagara Falls, Ont.—City Engineer D. T. Black's estimates for pavement on Palmer and Kitchener Streets were passed by the city council. St. Clair Ave. may also be paved as far as Queen St.

Oakville, Ont.—Town council will obtain an estimate on a Tarvia pavement for Park Ave. Clerk, W. E. M. Crawley.

Pembroke, Ont.—Town council is considering the construction of a concrete walk on the south side of Elizabeth St., from Moffat St. to Indian River. Town engineer, W. J. Moore.

St. Barnabe de Gatineau, Que.—Tenders will shortly be called for by A. A. Gelinas, St. Barnabe, Nord, Que., for gravelling the municipal road at a cost of $16,000. Engineer, M. Henry, Roads Department, Parliament Buildings, Que.

Stanbridge East, Que.—Municipal council decided to send delegates to meet the Provincial Minister of Roads, to urge immediate action by the government for the construction of the proposed highway between Lacolle and Knowlton. Mayor, H. Beatty.

Toronto, Ont.—Tenders, addressed to the Chairman, Board of Control, City Hall, Toronto, will be received up to noon, Tuesday, November 25th, 1919, for the construction of asphalt pavements, concrete curbings and concrete sidewalks on several streets. Specifications may be obtained at the Department of Works, City Hall.

Toronto, Ont.—The board of control decided to hold over the construction of the St. Clair pavement to Keele St. until the spring.

Toronto, Ont.—The Civic Works Committee decided to revive the Teraulay St. extension scheme, which was abandoned during the war period. It is suggested that the street be opened to a width of 86 ft., from College St. to Davenport Rd. Works Commissioner Harris will make a further report on the matter.

Victoria, B.C.—A petition has been presented to the provincial government by J. E. Armishaw, of Sayward, Salmon River, Vancouver Island, for an appropriation for the building of a main highway, from Campbell River, 38 miles north to Salmon River, and the erection of a bridge across the Campbell River,

Victoria, B.C.—The streets committee of the city council, on recommendation of City Engineer F. M. Preston, ordered that the matter of improvements for Lang St. be referred to next year's council.

Welland, Ont.—City council passed a by-law authorizing the opening of Pine St. through to Aqueduct.

WATER, SEWAGE AND REFUSE

Assiniboia, Man.—The rural municipality of Assiniboia intends to undertake the following improvements: The laying of water mains along Emo St. and Oakdean Rd., and the erection of a pumping station, the sinking of a well and supplying same with all necessary machinery, on Woodhaven Boulevard. Secretary-treasurer, Frank Ness, Kirkfield Park P.O., Man.

Brandon, Man.—City council decided to have several water mains laid in the east end of the city. City clerk, H. Brown.

Bridgeburg, Ont.—Tenders addressed to R. A. Land, clerk, Bridgeburg, Ont., will be received up to 6 p.m., November 17th, for the supply and installation of a 24-in. Bell and Spick cast-iron intake pipe 200 ft. long. Also the supply and installation of an intake crib. Plans and specifications may be seen at the clerk's office.

Galt, Ont.—Ald. S. J. McLane, chairman of the Board of Works, introduced by-laws at a recent meeting of the city council, providing for the construction of a sewer through Dickson Park and on James St., Myrtle Ave. and Huron St., and on Portland St., from Cambridge to Oxford St., and on Oxford St., from Portland St. to Dundas St.

Hamilton, Ont.—Works Committee recommended the extension of the Burlington St. sewer to serve the plant which the Firestone Tire and Rubber Co. will erect in Barton Tp. Estimated cost, $34,000. A water service is also being arranged.

Hamilton, Ont.—City Engineer E. R. Gray is completing plans for an overflow sewer system, and a by-law will be submitted to the ratepayers in January, provided the plans receive the sanction of the board of control. Approximate cost, $300,000.

Hamilton, Ont.—The recommendation of City Engineer E. R. Gray that two sewers be laid on Barton St., between East and Victoria Avenues, was endorsed by the Works Committee.

Lindsay, Ont.—At the last meeting of the town council, Engineer F. A. Dallyn, of the Provincial Board of Health, submitted a report on relief for the town's south ward system of sewerage, in which he recommended the construction of three disposal plants.

Moose Jaw, Sask.—City council awarded a contract for 20 man-hole frames to the Standard Foundry Co., Longueuil, Que., at $18 each, f.o.b., Longueuil.

Niagara Falls, Ont.—Tenders will be received by W. J. Seymour, city clerk, City Hall, until 4 p.m., on Monday, November 17th, for the construction of sewers on Elm and Morrison Streets, Homewood, Fifth and Sixth Avenues. Plans and specifications may be seen at the city engineer's office, Bamfield Block.

Niagara Falls, Ont.—City Engineer D. T. Black will call for tenders for the construction of several sewers.

Pembroke, Ont.—Town council is considering the extension of water main on Fischer St.

Pembroke, Ont.—The Provincial Board of Health has approved the following works to be constructed by the town council: Waterworks mains in McAllister St., from McKay to Commercial St., and in Isabella St., from Maiden Lane to Doran St. Sewer extensions in Bell, Fraser, Pembroke and Cecilia Sts, in the East Ward, and in Christie and Somerset Sts., Government and Forced Roads in the West Ward. Town engineer, W. J. Moore.

Port Arthur, Ont.—The Utilities Committee authorized the laying of a temporary water main on Montreal St.

Sandwich and Ojibway, Ont.—Proposals will be received by the Essex Border Utilities Commission until November 27th, for completing the South Sewage Interceptor in Sandwich and Ojibway, Ont. Plans and specifications may be obtained at the office of Morris Knowles, Ltd., 66 Ouellette Ave., Windsor, Ont.

Scarboro Tp., Ont.—The township council decided to submit to a vote of the ratepayers on January 1st the proposition to lay out a water system for the southwest corner of the township. The section to be served is bounded by Danforth Ave., the waterfront, the city limits and Kennedy Road.

Stratford, Ont.—The by-law providing for repairs to the Abraham Archer drain was given the necessary three readings and passed by the city council. City engineer, A. B. Manson.

LIGHT, HEAT AND POWER

Minnedosa, Man.—J. M. Leamy, Provincial Power Commissioner, Winnipeg, will direct operations for the erection of a power plant for the supply of electrical power to Minnedosa. The plant will be of a temporary nature, pending investigation as to whether or not the town could be supplied with power economically from Winnipeg.

Port Elgin, Ont.—Ratepayers passed the by-law to secure Hydro power.

Regina, Sask.—Ratepayers passed a by-law granting a franchise to the McLaws Syndicate for natural gas.

Saskatoon, Sask.—Tenders will be called shortly by the High School Board for necessary alterations in the hydraulic pumps in the steam heating plant of the Saskatoon Collegiate building.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m., on Monday, December 1st, 1919, for the supply and installation of six 1,000 k.v.a. step-down, single-phase transformers for the city light and power department. Specification may be obtained at the office of the city light and power department, 54 King St.

Winnipeg, Man.—Tenders, addressed to the Chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, November 17th, 1919, for the manufacture, delivery and erection in the power house of the city of Winnipeg at Point du Bois of two units of horizontal shaft turbines for direct connection to alternating current generators and governors for controlling same. Specifications may be obtained at the office of the City Light and Power Department, 54 King Street.

RAILWAYS

Guelph, Ont.—The operation of the Guelph Radial Railway, in conjunction with the proposed system from Hamilton to Galt and Kitchener was urged on the city council on November 3rd, by Sir Adam Beck, who submitted the report of the Hydro-Electric Power Commission on the condition of the railway. He also forecast the construction of a line from Galt, past Puslinch Lake to Guelph, which would be a feeder for the Guelph radial. Sir Adam estimates that an expenditure of $150,000 would be necessary to put the Guelph road in good running order.

Manitoulin Island, Ont.—A party of C.P.R. officials, including Vice-President Grant Hall, recently visited Manitoulin Island to investigate the needs and possibilities of a railway on the island.

North Bay, Ont.—A survey party, which set out last spring to find a route for the contemplated extension of the

ESSEX BORDER UTILITIES COMMISSION

Proposals will be received by the Essex Border Utilities Commission until November 27th for completing the South Sewage Interceptor in Sandwich and Ojibway, Ont.

The work consists of laying approximately the following lengths of reinforced concrete lock-joint pipe in four-foot lengths, which is now on the work.

42" diameter—16'
39" " —4360'
27" " —4320'

Building fifteen (15) concrete and brick manholes and setting cast-iron frames and covers; pumping and clearing out four thousand (4,000)feet of existing sewer 42" and 27" in diameter, and shaping up ditches; replacing 80 sq. yds. of concrete street pavement.

The depth of the excavation is approximately 13—15 feet consisting of sand and clay.

The work lies along a concrete-paved roadway, and is readily accessible. The contractor will be required to furnish suitable pumping equipment.

Plans and specifications may be obtained at the office of Morris Knowles, Ltd., 66 Ouellette Ave.

Essex Border Utilities Commission.

GORDON McGREGOR, Chairman. W. J. BAXTER, Secretary. 374

WANTED.—Tarpaulins wanted, state size, condition and price. Box 27, *The Canadian Engineer*, Toronto.

WANTED.—Salamanders wanted, state condition and price. Box 29, *The Canadian Engineer*, Toronto.

T. & N.O. Railway, from Cochrane to James Bay, has been compelled to abandon the work and return to North Bay in consequence of inability to secure proper help for packing supplies. The party, it is reported, had covered about 100 miles, which is half the distance to James Bay. J. Maher, the engineer in charge of the work, has hopes of completing the work next year, and, in the meantime, he will prepare and submit a report on what has been accomplished this season. The survey party, Mr. Maher states, found a fairly good route over the first 75 miles, but beyond that the country was very largely muskeg and swamp. Railway building through that district will be possible, but very difficult.

Ottawa, Ont.—Hon. C. J. Doherty stated in the House of Commons on November 10th that it would cost approximately $1,750,000 for laying steel on the Hudson Bay Railway from Kettle Rapids to Port Nelson. He also said that the government does not propose to purchase the Edmonton, Dunvegan and British Columbia Railway at the present time.

Quebec, Que.—It is rumored here that the Delaware & Hudson Railway proposes to purchase a chain of small railroads in Quebec district. The company may also build new lines and extensions, including one to the Quebec bridge.

Quebec Province.—An unofficial report states that the Canadian Pacific Railway is considering the advisability of extending its Kipawa branch to the northward, for the time being to terminate near the north end of Lake Timiskaming which would necessitate the construction of about 65 miles of line.

Windsor, Ont.—Representatives of nine border municipalities, Windsor, Walkerville, Ford City, Sandwich, Ojibway, Sandwich East township, Sandwich West township, Anderdon township, Tecumseh and Amherstburg, decided to have the ratepayers vote December 6th on the question of authorizing the Hydro-Electric Power Commission of Ontario to purchase the Sandwich, Windsor and Amherstburg Railway for $2,039,000.

FACTORIES AND LARGE BUILDINGS

Alcomdale, Alta.—A new townsite, on the line of the E., D. & B.C. Railway, to be known as "Alcomdale," has been incorporated. Several companies will erect buildings, including the E., D. & B.C. Railway, and the Gillespie Elevator Co.

Biggar, Sask.—Tenders will be received up to November 28th, 1919, for the erection of a Union Hospital Nurses' Home and Isolation Hospital. Plans and specifications may be obtained at the office of J. Melrose Morrison, architect, Saskatoon, Sask.

Brantford, Ont.—A by-law may be submitted to the ratepayers to authorize the erection of a new grand stand at Agricultural Park at a probable cost of $50,000. City clerk, H. F. Leonard.

Benton, N.B.—Robert Hay, of Woodstock, N.B., is making arrangements to build a mill here.

Calgary, Alta.—The Alberta Stock Yards Co. contemplates improvements to their stockyards, including new buildings.

Calgary, Alta.—The Universal Motor Cars, Ltd., will erect a garage.

Campbellton, N.B.—The Fraser Co., Ltd., will erect two new lumber mills here.

Cloverdale, B.C.—A new station is to be erected by the British Columbia Electric Railway on their Fraser Valley line at Hunt Rd.

Earl Grey, Sask.—A movement is on foot here for the erection of a memorial hospital.

Drummondville, Que.—The H. W. Gossard Co., Inc., Chicago, have decided to erect a plant here. Estimated cost, $75,000.

Fort William, Ont.—The Sugar Products Co., of New York, has secured a site in this city and will build a large storage warehouse.

Fort William, Ont.—The Fort William Arena Co., Ltd., has been incorporated for the purpose of erecting a rink. C. H. Jackson is one of the provisional directors.

Fredericton, N.B.—Improvements are to be made to the Y.M.C.A. building.

Galt, Ont.—The city council gave the first and second readings to a by-law to loan $20,000 to the Perfect Machine Co. for the purpose of extensions. It is expected it will go to the electors in about six weeks' time.

Galt, Ont.—Galt may have a municipal aerodrome, since this city has been chosen as a location on one of the aerial routes mapped by the Aero Club of Canada. Lt.-Col. W. G. Barker, president of the club, will take the matter up with the civic authorities.

Glace Bay, N.S.—The erection of a new central school will likely start in several weeks' time. The building is to be a wooden structure, 36 by 70. Plans and specifications have been prepared by J. H. Morley. Estimated cost, $35,000.

Halifax, N.S.—Contract let to M. E. Kiefe for building a new wing to the Holy Heart Seminary, according to plans prepared by A. E. Priest. Tender price, $80,000.

Halifax, N.S.—School Board proposes to erect a new school in the west end of the city.

Hamilton, Ont.—Construction of another unit of the technical school, which is being urged by Principal G. L. Sprague, will likely be started next year.

Hamilton, Ont.—In a report on the city's proposed athletic field, Engineer E. R. Gray estimates the cost of construction to be $106,000, this figure to include two grandstands with a seating capacity of 2,000 each. A by-law will likely be submitted to the ratepayers in January.

Hamilton, Ont.—The ratepayers of Barton township ratified both by-laws providing for a fixed assessment for the Firestone Tire and Rubber Co., which proposes to erect an immense plant in the township. Plans of the buildings have been completed and contracts will be let within a few weeks.

Hamilton, Ont.—A permit has been issued to the Duncan Lithographic Co., for an addition to their plant on Bay St. N., at a cost of $10,000.

Kingston, Ont.—Plans are under way for the erection of a new school building in Seeley's Bay district.

Kingston, Ont.—A movement is on foot by the civic hotel committee for the erection of a new hotel next year.

Kitchener, Ont.—The Kitchener Housing Commission has closed a contract with W. N. McEachren Sons, Ltd., for the erection of houses to relieve the shortage here. It is expected that before spring over a hundred houses will be available.

London, Ont.—The I.O.D.E. will erect a war memorial Children's Hospital, which will likely be located on the grounds of Victoria Hospital.

London, Ont.—The London Life Insurance Co., has announced that it will begin the erection of a new office building next year at a cost of more than half a million dollars.

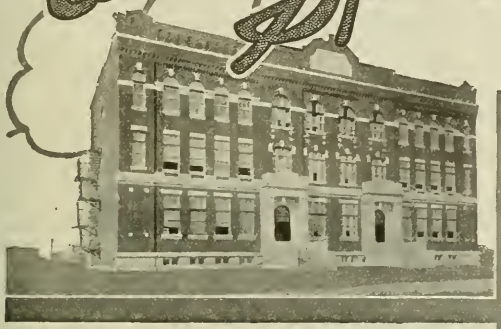
London, Ont.—Contract let to Hyatt Bros. for the erection of a $200,000 addition to the plant of the McClary Manufacturing Co.

London, Ont.—The London Chamber of Commerce has announced that a large factory, requiring several acres of land, has been secured for this city, and that it has already bonded a valuable site. The name of the industry will not be given out until the officers of the concern reach this city, which will be in a few days.

London, Ont.—The Western Fair Board has requested the city council to submit a by-law to the ratepayers on January 1st, authorizing the purchase of additional land and erection of new buildings at the Western Fair Grounds. Approximate cost of buildings, $1,025,000.

Manitoba Province.—Applications for the creation of hospital districts under the Municipal Hospital Act from Birtle, Deloraine, Melita, Pipestone, Souris, Eriksdale and

Barrett Specification Roofs



20-Year Barrett Specification Roof on St. Marc's School, Montreal. Owners: Catholic School Board, Montreal. Architects: Vautrin & Bernier, Montreal. Gen. Cont.: Ulric Boileau, Limited, Montreal. Roofers: Canada Roofing & Paving Company, Montreal.

20-Year Barrett Specification Roof on Old Orchard Avenue School, at Notre Dame de Grace. Owners: School Commissioners of Notre Dame de Grace, Montreal. Architects: Audet & Charbonneau, Montreal. Roofers: Tremblay & Francoeur, Montreal.

The *modern* way to buy a roof—

When the two school buildings shown above were completed, we handed their owners, the Catholic School Board of Montreal, Surety Bonds which *guarantee* the roofs against trouble or maintenance expense for a period of *20 years*.

The probabilities are that these roofs will last for nearer *30 years* without attention.

This is the *modern* way of buying a roof, not merely purchasing so many square feet of roof at so much per square foot, but investing in a long and definite period of *guaranteed service*.

The Barrett Specification first made it possible for building owners everywhere to obtain, through their local contractors, *a standardized roof* built according to the most scientific principles of roof construction.

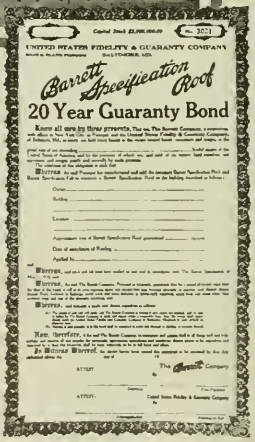
Guarantee 20 Years of Service

Now we offer to go a step further and actually *guarantee* a Barrett Specification Roof *for a period of at least 20 years!*

This guarantee, obtainable on any roof of 50 squares or more, in any town of 25,000 or over, and in smaller places where our Inspection Service is available, is in the form of a Surety Bond, issued by a well-known fidelity company.

To obtain the Bond you have only to insert in your building specifications the following:

"The roof shall be laid according to The Barrett Specification dated May 1, 1916, and the roofing contractor shall secure for me (or us) the 20-Year Guaranty Bond therein mentioned."



UNITED STATES FIDELITY & GUARANTY COMPANY
BALTIMORE, MD.

Barrett Specification Roof
20 Year Guaranty Bond

This is the bond that guarantees your roof for twenty years.

The guarantee costs you nothing. We merely require an opportunity to send our Inspectors to watch the job during construction.

You get a roof that will cost less per year of service than any other type of permanent roof, and that takes the base rate of insurance. We get the satisfaction of knowing that our materials are creditably used.

We should be very glad to send you further details and copy of the Barrett 20-Year Specification, with diagrams, ready for insertion in your building plans.

The Barrett Company
LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Russell have been approved by Hon. J. W. Armstrong, provincial secretary. The aggregate cost will be approximately $200,000.

Mimico, Ont.—Ford and Clark, local real estate agents, will erect an apartment, store and office building.

Moncton, N.B.—A movement is on foot for the erection of a rink. B. E. Reardon is interested.

Moncton, N.B.—Tenders will be received up to noon, November 17th, 1919, for the erection of new offices, etc., for the Atlantic Underwear Co., Ltd. Plans and specifications may be obtained from J. W. Fraser, architect, 132 Steadman St., Moncton, N.B.

Nanoose, B.C.—The Nanoose Lumber Co., Ltd., will erect a mill near here. Manager, Chas. R. Hardy.

New Westminster, B.C.—Contract for the erection of the Canada Western Cordage Company's plant at Sapperton has been let to the E. J. Ryan Contracting Co., Ltd., of Vancouver, at $76,000. The contract calls for the erection of administration buildings, warehouse and factory building 150 by 200 ft., to be constructed of interlocking tile and reinforced concrete.

New Westminster, B.C.—A proposal to utilize the old jail for the purpose of a technical school, making structural alterations to the building, has been placed before Hon. J. D. MacLean, Minister of Education and Provincial Secretary, Victoria, B.C., by the school trustees of this city. Estimated cost of alterations about $12,000.

Niagara Falls, Ont.—The by-law to raise $50,000 for additions to the hospital will be resubmitted to the ratepayers at the January elections.

Oakville, Ont.—Tenders addressed to Molesworth, West & Secord, architects, 808 Royal Bank Building, Toronto, will be received till 12 noon, on November 15th, for the erection of a public school at Oakville. Plans and specifications may be seen at the office of the architects, or of the secretary of the Board of Education, Oakville.

Oakville, Man.—A movement is on foot for the erection of a rink here.

Ottawa, Ont.—It is expected that the work of reconstructing the Parliament buildings will be completed in time for use at the next session of Parliament, according to a statement made by Hon. A. L. Sifton, Minister of Public Works. To date reconstruction has cost in the neighborhood of six million dollars and about two million dollars more will have to be expended.

Ottawa, Ont.—The government have decided to go ahead with the reorganization of the printing bureau and have tabled an estimate in the House for $275,000, part of which is to cover the cost of structural alterations and the purchasing of new machinery.

Ottawa, Ont.—The city council has decided that the Reid Farm property, Parkdale and Carling Avenues, is the best location for the new civic hospital. Twenty-six acres of land is being acquired at a cost of $77,850 and plans will now be prepared.

Ottawa, Ont.—The possibility of Queen's University establishing one of the best medical colleges in Canada, in Ottawa, on a site adjacent to that for the new civic hospital, has almost become a surety. Last Monday a committee from the college faculty conferred with the Board of Control and members of the Civic Hospital Committee.

Penetanguishene, Ont.—The McGibbon Lumber Co. may rebuild their mill which was recently destroyed by fire.

Peterboro, Ont.—The city commissioners have accepted the tender of the Dominion Bridge Co. for the supply of steel for the new telephone building. The amount involved is $18,290, being 148 tons of steel at $123.58 per ton. It is expected that the contract for the construction of the building will be awarded to J. Dunlop at $80,468.

Port Arthur, Ont.—The Great Lakes Paper Co., Ltd., will commence immediately the erection of a huge plant costing between $5,000,000 and $6,000,000, just east of Port Arthur city limits. The plant is to consist of a groundwood mill with an annual output of 30,000 tons, a sulphite mill, annual capacity 7,500 tons and a newsprint paper mill of 3,330 to 3,500 tons annual output. Power from the Hydro-electric plant at Nipigon will be used, from 12,000 to 16,000 h.p. being contracted for delivery at the plant, at a cost of $17.50 per h.p., by December 31, 1920. Engineers headed by Hardy Ferguson, of New York, are to be on the ground within a few days. Foundations will be commenced at once, if weather permits. The plant is to be in full operation by June, 1921. The personnel of the company is: Lewis L. Alsted, president, Combined Locks Paper Co., Wis.; George Seaman, president, Seaman Paper Co., Chicago; and James Whalen, president, Port Arthur Shipbuilding Co. The firm is to employ thousands of men in construction and operation. A site of 100 acres has been given free by J. J. Carrick out of his 600-acre holdings immediately east of Port Arthur. Port Arthur will extend its street railway to the site.

Port Coquitlam, B.C.—The Great War Veterans of this district propose to erect a memorial hall and club headquarters. Committee in charge, Messrs. Kidd and Irvine.

Port Coquitlam, B.C.—The Gregory Tire and Rubber Co. will erect a plant here at a cost of $175,000, providing the provincial government approves of a by-law to grant the company a bonus of $40,000. The managing director of the company is J. A. Cunningham, president of the B.C. Manufacturers' Association.

Port Haney, B.C.—School board is considering the erection of school buildings.

Quebec, Que.—Negotiations are pending which involve the transfer of the Montcalm Hotel property into the hands of an hotel syndicate, of which Frank A. Dudley, of Niagara Falls, N.Y., is president. The erection of a large new hotel on the site is planned.

Quebec, Que.—The Catholic School Commission is considering the erection of new schools in the Sacred Heart parish. Chairman, J. B. Morissette.

Raleigh Tp., Ont.—A new school will be erected in School Section No. 16. Building Committee: Charles Obrey and Fred. Holland.

Redcliff, Alta.—An enlargement is to be made to the plant of the Dominion Glass Co., at a cost of $100,000, the chief expense being the installation of a new furnace.

Regina, Sask.—Contract let to J. G. Traub for the erection of a showroom and service station for the Willams Motor Co., on Cornwall St. Work has started. Estimated cost, $30,000. Architects, Storey & Van Egmond.

Regina, Sask.—Plans are under way for the erection of a community hall in connection with the Imperial Oil Company's works. Estimated cost, $20,000.

Saskatoon, Sask.—At a recent mass meeting held here it was unanimously decided to build a $30,000 hockey rink.

Saskatoon, Sask.—The High School Board decided to urge upon the city council the preparation of a by-law for submission to the ratepayers in December, authorizing the construction of extensions to the present building amounting to $300,000. Chairman, A. M. McIntyre.

Saskatoon, Sask.—Among the buildings to be erected in this city next year are the following: Addition to the Collegiate Institute, $300,000; Normal School, public school, King George Hotel and City Hospital.

Sherbrooke, Que.—A movement is on foot by the I.O.D.E., for the erection of a tubercular sanatorium.

Ste. Agathe, Que.—The Provincial government will shortly grant a large sum of money for the enlargement of the tubercular hospital here, according to a statement made by Hon. Walter G. Mitchell, provincial treasurer.

St. Catharines, Ont.—St. Catharines will be one of the stopping places on the aerial route which is being planned, and the city council has been asked to give its views with reference to the building of an aerodrome here. A committee will make a report on the subject.

St. John, N.B.—After discussing the need for a new municipal building, costing $1,000,000 to $2,000,000, the local board of trade decided to urge the city council instead to restore the municipal court house, which was gutted by fire last winter.

Burlington Steel Co., Ltd.
Hamilton, Canada

STEEL BARS
For
Concrete Reinforcing

THE MOST IMPORTANT FACTOR IN CONCRETE REINFORCEMENT IS THE TENSILE STRENGTH AND ELASTIC LIMIT OF THE REINFORCING BAR.

OTHER THINGS BEING EQUAL, STEEL HAVING THE HIGHEST ELASTIC LIMIT, OR YIELD POINT, WILL BE THE MOST SATISFACTORY FOR REINFORCEMENT. WHEN UNDER STRAIN, AS SOON AS THE ELASTIC LIMIT OF ANY REINFORCING BAR IS REACHED, THE METAL STRETCHES RAPIDLY DECREASING IN SECTION, DRAWING LOOSE FROM THE CONCRETE AND DESTROYING THE MONOLITHIC BOND EXISTING BEFORE THIS POINT IS REACHED THEREFORE, THE SAFETY OF THE ENTIRE CONSTRUCTION IS IN DIRECT PROPORTION TO THE ELASTIC LIMIT OF THE STEEL USED.

THE ELASTIC LIMIT OF RAIL CARBON STEEL IS 50,000 TO 60,000 POUNDS PER SQUARE INCH, EITHER TWISTED OR PLAIN, AS COMPARED WITH AN ELASTIC LIMIT OF 25,000 TO 30,000 POUNDS IN SOFT STEEL.

THAT'S WHY RAIL CARBON STEEL, WITH ITS 80,000 POUNDS MINIMUM TENSILE STRENGTH, IS RECOMMENDED AS BEING FAR SUPERIOR FOR ALL KINDS OF REINFORCED CONCRETE WORK.

AT OUR HAMILTON, ONT., WORKS WE BUY SELECT RAILS, AND ROLL THEM INTO RAIL CARBON STEEL REINFORCING BARS IN A PLANT WHICH IS THE EMBODIMENT OF THE LATEST THOUGHT AND PRACTICE

THESE BARS CAN BE SUPPLIED FROM STOCK IN VARIOUS SIZES, LENGTHS AND SHAPES. WE CAN ALSO ROLL SPECIAL SHAPES AND SIZES TO FIT YOUR PARTICULAR REQUIREMENTS.

Bars bent to shape for Beams, Stirrups, Etc.

PROMPT SHIPMENT

Stratford, Ont.—The Canadian General Electric Co. has purchased the Mooney buildings in this city, and will remodel same and install new machinery for the manufacture of electrical appliances.

Toronto, Ont.—A site has been purchased for the erection of a library building in Earlscourt district and work will likely start next spring. Estimated cost, $50,000.

Toronto, Ont.—The following building permits have been issued by the city architect: H. Grieman, six-story brick warehouse, 129-139 Spadina Ave., near Richmond St., $100,000. Anthracite Briquette Co., two-story warehouse, north side Commissioner St., near Ashbridge's Bay, $9,600. Prince's, Ltd., alter building formerly occupied by Fairweather, 84-88 Yonge St., $30,000.

Toronto, Ont.—M. Mitchell has taken out a permit to erect a five-story solid brick warehouse at the north-east corner of King and Simcoe Streets, at a cost of $681,000.

Toronto, Ont.—The plans for the new sub-post office, corner of Carlaw and Danforth Avenues, have been completed and forwarded to the postmaster-general's department at Ottawa for approval.

Toronto, Ont.—Mayor Church is taking up with the C.P.R. the question of erecting a new station in Riverdale, and with the G.T.R. the erection of a new station north of St. Clair to replace the present Davenport station.

Trenton, Ont.—A new rink will be erected on Quinte St. Clerk, J. W. Delaney.

Unionville, Ont.—The municipal council have instructed the E. A. James Co., Ltd., 36 Toronto St., Toronto, to prepare plans for a township memorial hall. The building will cost approximately $20,000. A by-law will be submitted to the people on January 1st.

Vancouver, B.C.—George Taylor, of the firm of Leitch and Taylor, 413 Granville St., is the man behind the scheme for the erection of a $600,000 apartment house at the corner of Bute and Barclay Streets.

Vancouver, B.C.—The Merchants Bank has purchased a site on the west side of Granville St., and will erect a new bank building early next year. Superintendent, A. C. Fraser.

Victoria, B.C.—Contract let to J. Halkett and E. J. Hunter, at $10,375, for erection of annex to Oakland School.

Walkerville, Ont.—The school board decided to establish a continuation school here.

Waterloo, Ont.—The Waterloo Curling Club has purchased a building for use as a rink, and will erect an addition to same. President, J. J. Weir.

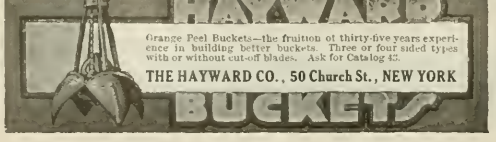
Welland, Ont.—City council received a letter from Lieut.-Col. W. G. Barker, president of the Canadian Aero Club, stating that as Welland is on one of the important aeroplane routes it is desirable that an aerodrome should be erected here.

West Toronto, Ont.—W. Speers will erect a three-story building on Dundas St., opposite Medland St.

White Rock, B.C.—At a recent meeting of the G.W.V.A., local taxpayers and the White Rock A. and H. D. Association, it was decided that the White Rock War Memorial should take the form of a combined club-house for veterans and a public library, the building to be erected at an estimated cost of $10,000.

Windsor, N.S.—The Alumni Association of King's College decided to raise funds to the amount of $50,000 for the erection of a memorial hall.

Windsor, Ont.—The Burroughs Adding Machine Co., Detroit, has purchased a site and will erect a plant here.



HAYWARD
Orange Peel Buckets—the fruition of thirty-five years experience in building better buckets. Three or four sided types with or without cut-off blades. Ask for Catalog 47.
THE HAYWARD CO., 50 Church St., NEW YORK
BUCKETS

Windsor, Ont.—Application for a charter is being made by the Border Cities Hotel Co., which is to erect a million-dollar nine-story hotel here. Among the provisional directors are Hiram H. Walker and Gordon McGregor.

Windsor, Ont.—The St. Clair Country Club, Ltd., plans erection of a new clubhouse next season. President, Col. E. S. Wigle.

Windsor, Ont.—The Auto Specialties Co. have commenced building operations on their 10½-acre site in this city. Their first unit will involve one large and three small buildings, having a total floor space of about 50,000 square ft. When completed and equipped, this unit will represent an investment of fully $200,000. The plant will eventually cover the entire site. Work on the second unit will commence next summer. The construction contract is in the hands of S. E. Dinsmore & Co. The Canadian Bridge Co. are erecting the steel, and J. C. Pennington is associate architect with Davidson & Weiss, of Chicago.

Windsor, Ont.—Tenders will be received up to November 29th for the erection of the new $400,000 public school. Architect, A. H. McPhail.

Windsor, Ont.—Paul Gilbert has purchased a site on Wyandotte St., and will construct a large store and apartment block next summer. Estimated cost, between $20,000 and $25,000.

Winnipeg, Man.—City council is considering the erection of a new market building. City clerk, C. J. Brown.

Winnipeg, Man.—A permit for a $6,000 addition to the Canadian Malting Company's factory has been granted by the building inspector.

Winnipeg, Man.—A permit has been issued for the erection of an $85,000 emergency building to relieve the congestion in the present quarters of the University of Manitoba. Deputy Minister of Public Works, S. C. Oxton.

Woodstock, Ont.—On December 1st an industrial by-law will be submitted to the ratepayers authorizing a loan of $20,000 to the Warren Pipe Organ Co., Ltd., to enlarge their plant.

York Township, Ont.—Township council decided to proceed at once with work on the eight-roomed addition to Secord school. Township clerk, W. A. Clarke, 40 Jarvis St., Toronto.

MISCELLANEOUS

Calgary, Alta.—The following by-laws will be voted on by the electors at the coming municipal elections: Sewage disposal, $350,000; waterworks, $372,316; hospital, $135,000; Louise bridge, $155,978; total, $933,294.

Chilliwack, B.C.—Tenders for the work in connection with the Sumas reclamation scheme will shortly be called for by the provincial government. It is expected that the scheme will involve the expenditure of well over a million dollars, and the reclamation of some 32,000 acres of land in the now low-lying section in the vicinity of Chilliwack.

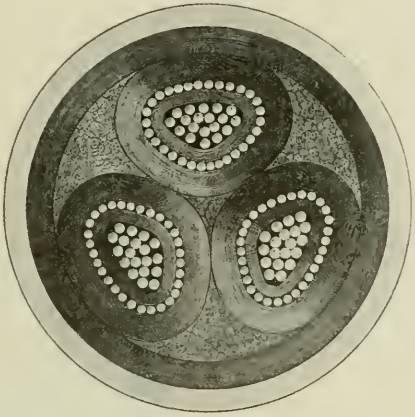
Fort William, Ont.—A large ore dock, capable of handling over 2,000 tons an hour, will be constructed here, according to information received by Mayor Murphy. Estimated cost, $100,000.

Hamilton, Ont.—New plans for the extension of the harbor improvements provide for a wall on the west side of Wellington St., and a slip 600 ft. wide, which will cost in the neighborhood of $160,000. It is proposed to extend the wall across to Wentworth St., filling in all the space behind it.

Hamilton, Ont.—The board of control voted down the recommendation of the Works Committee that a by-law be submitted to the ratepayers in January authorizing the expenditure of $25,000 on civic wading pools and $75,000 for the development of the mountain brow, as suggested in the report of Noulan Cauchon, town-planning expert.

Ladner, B.C.—In order to provide for necessary repair work to the diked area of Delta, the municipal council recently passed a by-law empowering the borrowing of $12,000.

SPLIT-CONDUCTOR CABLES



250,000 C.M. 3-CONDUCTOR 13,200 VOLT
PAPER-INSULATED, LEAD COVERED CABLE

Eugene F. Phillips Electrical Works, Ltd.

MONTREAL

Branches: Toronto, Winnipeg, Regina, Calgary, Vancouver

London, Ont.—By-laws aggregating more than $1,500,000 will go before the people in January next. They include $300,000 for extensions to the Western fair grounds; $200,000 for the London and Port Stanley Railway; $250,000 for the Board of Education for new schools, etc., $200,000 for the commencement of a new city hall; $100,000 for a new reservoir; $100,000 for new bridges; $85,000 for a new stable and shelter for vehicles for the city; $20,000 for additional playgrounds; and many other smaller items. In addition it appears likely that the citizens will be called upon to vote on the question of the purchase of the London Street Railway, which would mean at least another million and a half dollars.

Moose Jaw, Sask.—At the recent meeting held in this city in connection with the Moose Jaw water proposition, delegates from Riverhurst, Sask., raised the question of a much needed bridge across the Saskatchewan River, the extension of the Grand Trunk Pacific west to meet the C.N R. Eston-Dunblane line and the construction of a power dam to supply the country for a radius of 200 miles with power. The matter was introduced by Mr. McDonald, of Riverhurst. While it was considered that it was not a matter that could be taken up with the provincial government at the same time as the water proposal, it was felt that the traffic bridge at least should be pushed at Regina, and that the Dominion government should be communicated with as to the rest of the proposal. No definite action was taken on the matter by the meeting, but the Riverhurst delegates were assured of the heartiest co-operation of Moose Jaw.

Ottawa, Ont.—The time for receiving tenders for kitchen equipment for the Parliament Buildings, has been extended to noon, November 15th, 1919, and the date for the completion of this work has also been extended to February 7th, 1920. John A. Pearson, architect, Centre Block, Parliament Buildings, Ottawa.

Ottawa, Ont.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Wednesday, November 26, 1919, for the supply of eleven pontoon discharge pipes for dredge "P.W.D. No. 5." Plans and specification may be obtained at the offices of the mechanical superintendent of dredges, Birks Building, Ottawa and the superintendent of dredges, St. John, N.B.

Powell River, B.C.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Tuesday, November 25th, 1919, for dredging in front of wharf at Powell River, district of Comox-Atlin, B.C. Combined specification and form of tender may be obtained on application to the secretary, Department of Public Works, Ottawa, at the offices of the district engineers, Victoria, B.C., New Westminster, B.C., and at the post office, Powell River, B.C.

St. John, N.B.—The contract for dredging here has been awarded by the Dominion government to J. A. Gregory, of West St. John, the amount of the contract being twenty thousand yards at 33c. a yard.

Sydney Mines, N.S.—The Dominion Coal Co. will open a colliery in the vicinity, according to a statement made by Mark Workman, president of the company. Mr. Workman said that the new mine would be sunk at Bonner Point, in the Florence district, and intimated further that operations in that locality would be carried out on a large scale. Some two million dollars will be spent in developing these areas, installing the most modern equipment available and building miners' houses, which will be provided with a waterworks system. The president foreshadowed the establishment of steel shipbuilding on a large scale.

Toronto, Ont.—At a private conference with the Board of Control on November 10th, the Harbor Board secured consent to the issue of $4,000,000 of debentures for Toronto harbor development, $2,500,000 will be spent upon the inner harbor between Bathurst and Yonge Streets, and the bulkhead wall will be continued from Yonge St. eastward, with the marginal way and Fleet St. to the north of it, these two great highways, 84 and 86 ft. wide being designed as the great warehouse and loft-building thoroughfares of the Greater City.

Vancouver, B.C.—Aldermen Kirk, Shelly and Owen have been appointed a committee to represent the city council in co-operating with a committee of the Vancouver Real Estate Association to place before the harbor commissioners a definite plan for port improvement.

Vancouver, B.C.—Arrangements are being completed by Percy H. Fraser, of the Vancouver Magnetite Iron and Steel Smelting Co. for the installation of an electric smelter near this city, whereby the ores of this province will be broken and reduced to first-class pig iron. The company is capitalized at $1,000,000, and the plant is expected to cost $35,000.

Vancouver, B.C.—The deep sea shipping interests of Vancouver decided to petition the Dominion government to construct a floating drydock here.

Victoria, B.C.—It is reported here that the Dominion government plans to place contracts for fifty wooden schooners with British Columbia shipyards. According to the report, twenty-five of the ships will be constructed at this port, and the other half will be turned out by yards on the mainland.

A Weekly Paper for Civil Engineers and Contractors

Earth Slides in Winnipeg Aqueduct Construction

Description of the Principal Methods Used by the Contractors in Dealing with the Sloughs and Slides—Bearing Tests Demonstrated Instability of the Soft Dark Clay, Analysis of Which Showed 15% of Moisture and Water of Combination

By DOUGLAS L. McLEAN

Formerly Division Engineer, Greater Winnipeg Water District

EARTH slides in the open trench used for the construction of Winnipeg's 100-mile aqueduct were of such magnitude as to impede seriously the progress of the work. Considered by themselves, they afford an interesting study in the flow of clay under pressure and in the effect of water on the movement of large masses of earth; but viewed together with the other phases of the work, they appear as an index of the difficulties that had to be overcome in order to construct safely the aqueduct through the 10 miles of summit cut where peat bogs, 6 to 14 ft. deep, covered fine

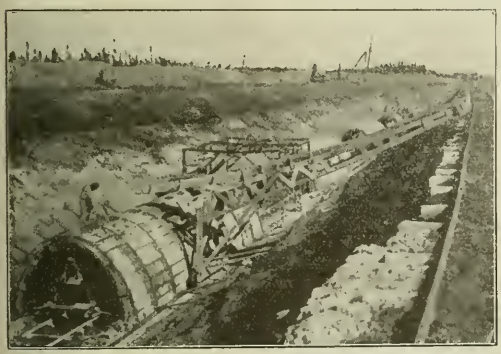

FIG. 1—INDICATING OPERATIONS IN BUILDING AQUEDUCT UNDER NORMAL CONDITIONS

sand, sandy clay and blue clay, which moved readily under comparatively light pressures.

Under normal working conditions, the water of the peat bogs was drained away along the centre line by means of a pilot ditch constructed by the contractor during the first years of his work. The Water District Railway's side-ditches to the south, and protective drainage ditches to the north, of the aqueduct line, also aided in the disposal of surplus surface waters. With the main volume of the water removed by these drains, the contractor's regular program of work was as indicated in Fig. 1.

First, the main trench, about 20 ft. deep, with 16 to 20-ft. base, was excavated with side slopes of 1: 1, by means

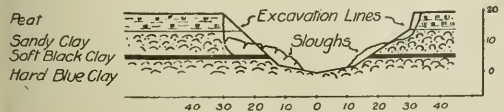

FIG. 2—DIAGRAM SHOWING SMALL SLOUGHS

of a Class No. 24 Bucyrus drag-line excavator, which placed the material removed into spoil banks 75 to 100 ft. on each side of the trench centre line.

With the spoil at such distances, there was ample room on the north for the travelling derrick, which was used to remove the final trimming taken out by hand labor just before the fresh invert concrete was placed; and room

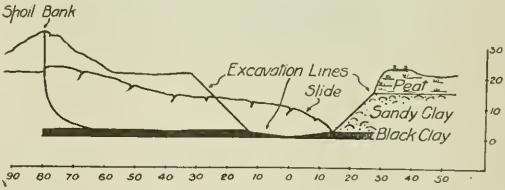

FIG. 3—DIAGRAM SHOWING SLIDE

was also left for the narrow-gauge railway which was used to transport the concrete from a central mixing plant to the forms used for moulding the aqueduct.

Pumps were spaced at intervals, depending upon the quantities of ground water that escaped into the trench, and, by aid of box-drains, kept the foundation in shape for final trimming and permitted the invert concrete to be placed in the dry. The concrete invert, or floor of the structure, was poured in 15-ft. sections, while the arch, or horse-shoe-shaped portion of the concrete pipe, was moulded in

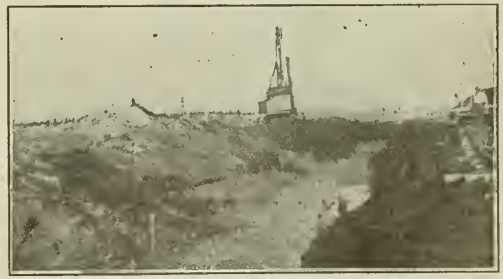

FIG. 4—SLIDE—NOTE SETTLEMENT OF SPOIL BANK

45-ft. lengths by use of steel forms. Reinforcement was placed in the invert where soft foundation was encountered. As soon as the concrete had been properly cured, the pipe was backfilled by the same drag-line that was used for the excavation.

With the spoil divided and placed well back from the trench, with excavation slopes of 1:1, and with drainage, there would appear to have been small possibility of slides; but even these precautions were not sufficient when the soft dark, waxy clay was encountered. This clay varied from a dark black to a pale gray color, depending upon the amount of drying it had received. When in its natural state it was very plastic and soft, but when air-dried it became extremely hard and showed great shrinkage. This stratum of soft clay occurred throughout long stretches of the trench and varied in thickness from 1 ft. to over 50 ft. In some places it occurred 5 or 6 ft. above invert grade, and in other places it occurred at the bottom of the excavation. In such places

FIG. 5—TRAVELLING DERRICK REMOVING PORTION OF SLIDE ALONG CENTRE LINE

as the latter, heavy inverts and piling were used to carry the structure. The chemical analysis of this clay was as follows:—

Moisture and water of combination ..	15.10%	Chromic oxide	1.40%
Silica	34.75%	Calcium	5.30%
Iron oxide	15.20%	Magnesium	3.25%
Alumina	24.10%	Sulphates	2.90%

The accompanying table gives some bearing tests to show the difference between this soft clay and other materials encountered on the work.

Whenever this clay was encountered, movement of the trench walls took place. These movements varied from local sloughing, as shown by typical example in Fig. 2, to large slides, as shown by typical examples in Figs. 3 and 4. In the latter cases, the spoil bank appeared to settle vertically and to squeeze the material into the open trench. This had the effect of cracking the earth and allowing water to get into the mass. This water lubricated the earth and soon accumulated a head which tended to produce further motion. In addition, the water under a head forced its way into otherwise impermeable material and extended its lubrication. This combination of water pressure and lubrication kept the materials moving from time to time at various rates of speed, depending on the local conditions. As an example of the manner in which this clay transmitted vibration: The drag-line runner dropped a cubic yard of solid clay from a height of 10 ft. above the bottom of the trench, to the north of the structure, which was carried on piles (see Fig. 7). Standing on the opposite bank, 60 ft. away and 18 ft. above, one could feel the jar from the impact of the earth on the trench bottom.

The principal methods employed by the contractor to overcome these slides were:—

1. On the section of trench where the soft clay occurred near the bottom of the trench, and where the structure was carried on piles by use of special inverts, the sliding material was moved far back, an extra width of trench bottom was excavated (see Fig. 7) and the bank was sloped at a flat angle. This removal of the slide, as it were, meant the handling of large quantities of excavation, and later, of backfill.

2. Where firm material lay under the sliding materials, the method adopted was to flatten one slope and remove by the Class No. 24 drag-line such material as it could reach from the opposite side of the slide. This flat slope was allowed to drain and harden by air-drying. Then the final excavation along the centre line was made (as shown by Fig. 5) by means of a travelling derrick and hand labor. This method did not involve the handling of as much earth

as did the first method, but it was only successful where the excavation was far ahead of the concrete work.

3. Pole-sheeting of the trench was used through a section of slide when the drag-lines were busy on other slides.

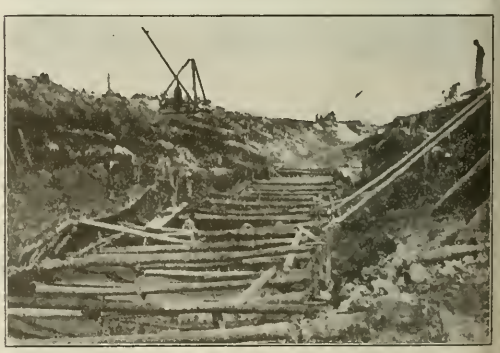

FIG. 6—SHEETING THROUGH SLIDE

This pole-sheeting and bracing is shown in Fig. 6. This was a slow method of work, as special overhead bracing was required to allow the steel forms to be moved along the trench. The overhead bracing used to hold the slides while the arch concrete was being poured, was not as heavy as the first bracing placed, as by drying out the material near the pole sheeting the pressures were reduced. This

method required the moving of the smallest quantities of earth, but used the maximum amount of common labor.

While these were the three principal methods used by the contractor, various other methods of depositing spoil, draining the trench sides and sloping the side of the trench were tried. Each section of slide had peculiarities of its own and had to be dealt with as sound judgment and experience directed. In some places special heavy inverts were all that was required to hold the earth in check, while nearby the side pressure was sufficient to move piling spaced

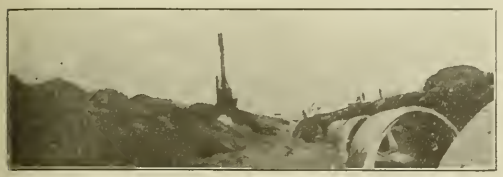

FIG. 7—SLIDE SHOWN IN FIG. 4 REMOVED AND AQUEDUCT CONSTRUCTED

at 3-ft. intervals and cross-braced with 12-in. round timbers. Theoretically, water could be held to be the cause of all these slides, as it destroyed the cohesive qualities of the soft clay; its pressure acted as equivalent of millions of jack-screws and it further helped movement by lubrication; but in such cases as these slides, theory was of little use and reliance had to be placed on experience and sound judgment. In the employment of such, the Winnipeg Aqueduct Construction Co. were fortunate in having Wm. Smaill as field superintendent and manager, while the Greater Winnipeg Water District were equally fortunate in having W. G. Chace as chief engineer.

RECENT PUBLICATIONS

MUELLER BRASS GOODS.—Cloth-bound catalogue, 8¼ by 11 ins., 276 pages and cover, printed on coated paper, profusely illustrated; issued by the H. Mueller Manufacturing Co., Ltd., Sarnia, Ont., describing their water, plumbing and gas brass goods.

CONCRETE TANKS FOR INDUSTRIAL PURPOSES.—A 36-page illustrated pamphlet, 6 by 9 ins., published by the Portland Cement Association, illustrating and describing concrete tanks for water, mineral oils, brine, molasses, vegetable and animal oils, tanning liquids, dairy products, chemical solutions, etc.

QUEBEC STREAMS COMMISSION.—Seventh report, covering year 1918; 120 pages and paper cover; 6¾ by 9¾ ins.; illustrated; accompanied by several folded maps anl diagrams. O. Lefebvre, of Montreal, is chief engineer and secretary of the commission. Two of the three commissioners are civil engineers, namely, W. I. Bishop and Arthur Amos. The chairman of the commission, S. N. Parent, is a lawyer.

WROUGHT TUBULAR PRODUCTS.—Catalogue issued by the Page-Hersey Iron, Tube & Lead Co., Ltd., 100 Church St., Toronto; printed in two colors on coated paper; well illustrated; 76 pages and cover, 4½ by 7½ ins. It includes illustrations, weights, dimensions, diagrams and specifications for lap-welded and butt-welded pipe; pipe with flanged joints and bell and spigot; electric line tubular poles, service clamps, well tubing, etc.

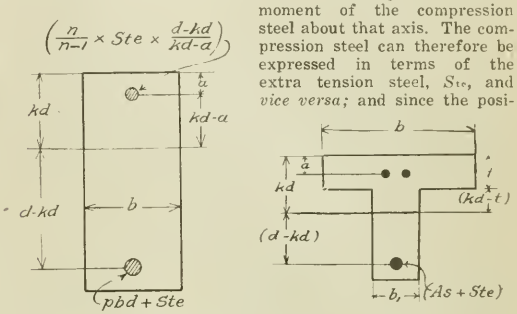
PROVINCE OF SASKATCHEWAN.—Booklet prepared by F. H. Kitto, under the direction of the Superintendent of the Natural Resources and Intelligence Branch, Ottawa; 154 pages and paper cover, 6½ by 9¾ ins. The contents include chapters on historial description, government, transportation, communication, education and religion, climate, soil, agriculture, cities and towns, forests and water powers, minerals, fish and game; illustrated by maps, charts and half-tones.

DOUBLY REINFORCED CONCRETE BEAMS

BY E. MONTGOMERY
Regina, Sask.

AT times structural requirements limit the concrete section of a beam and it becomes necessary to add compression steel to enable it to sustain a given bending moment. In such cases the amount of tensile and compressive reinforcement required can be found by the following method.

When compression steel is used, the amount of ordinary tension steel, pbd, is increased by an amount, S_{te}, the first moment of which about the neutral axis is equal to the first moment of the compression steel about that axis. The compression steel can therefore be expressed in terms of the extra tension steel, S_{te}, and *vice versa;* and since the position of the neutral axis in a reinforced concrete section depends only upon the modular ratio and unit working stresses in concrete and steel, when these and the concrete section are given, the position of the neutral axis is fully known.



With the preceding remarks in mind, the theory applied to the solution of the following problem will be clear.

Example.—It is required to reinforce a concrete section 14 by 27 ins. to sustain a bending moment of 1,081,920 inch-lbs. The depth of embedment of both tensile and compressive reinforcement is to be 3 ins.; working stresses in concrete and steel to be 640 lbs. per sq. in., and 16,000 lbs. per sq. in. respectively, and the modular ratio to be 15.

$$I = Mkd/f_c, \text{ or } nM(d-kd)/f_s.$$

Also, $I = b(kd)^3/3 + npbd(d-kd)^2 + nS_{te}(d-kd)(d-a)$.

For the given stresses and modular ratio, $k = 0.375$ and $p = 0.0075$. Since the effective depth of section is 24 ins., $kd = 9$ ins.; $(d-kd) = 15$ ins.; $(d-a) = 21$ ins.; $pbd = 2.52$ sq. ins.

Substituting and equating:—

$14\times 9^3/3 + 15\times 2.52\times 15^2 + 15S_{te}\times 15\times 21 = 1{,}081{,}920\times 9/640.$

$\therefore$ 4,725 S_{te} = 3,307.5.

$\therefore$ S_{te} = 0.7 sq. in.

pbd = 2.52 sq. ins.

$\therefore$ Total tension steel = 3.22 sq. ins. and compression steel $= 15/14\times 0.7\times 15/6 = 1.875$ sq. ins.

In solving for T-beams of given concrete section, the only variation is in the method of computing the amount of ordinary tensile reinforcement. This is done as follows:—

Sum of compressive stresses $= A_c f_c/2 = b_1 kdf_c/2 + t(b-b_1)[f_c + f_c(kd-t)/kd]\times \frac{1}{2} =$

$$(f_c/2)[b_1 kd + t(b-b_1)(2-t/kd)].$$

Casting out $f_c/2$, concrete compression area $= A_c = b_1 kd + [t(b-b_1)(2-t/kd)]$. This equation appeared in an article by the writer on page 458 of *The Canadian Engineer* for April 15th, 1915.

Ordinary tension steel $= A_s = A_c f_c/2f_s$.

As before, $I = Mkd/f_c$, or $nM(d-kd)/f_c$.

Also, $I = b(kd)^3/3 - (b-b_1)(kd-t)^3/3 + nA_s(d-kd)^2 + nS_{te}(d-kd)(d-a)$.

The Union of Alberta Municipalities has asked the provincial government to make an investigation of the hydro-electric possibilities of Alberta, with a view to formulating a policy for publicly owned power plants. A resolution to this effect was adopted at the Union's recent convention.

THE PLANNING OF LAND IN RELATION TO MUNICIPAL AND SOCIAL PROBLEMS*

By Thos. Adams
Town Planning Adviser to the Dominion Cabinet

IN Canada and the United States the land has been planned, but not scientifically. As a rule, land has been planned on the lines that are easiest, and with little regard to economic use and natural conditions, or on the lines that suit the narrow point of view of the private speculator. We have witnessed the folly of that haphazard and wasteful method; nearly every municipality on this continent is paying the cost of bad planning.

All municipal government centres in the various phases of land development, both in town and country. Every public utility has to obtain its justification from the service it renders to land and improvements erected upon it; and the cost of government is high or low in proportion as the land is wisely or unwisely developed. We need scientific planning in both our rural and our urban districts, and it must have for its primary object the development of our resources (including human life) and the increase of production.

Must Apply Scientific Principles

We need only fear increase of population and over-production if we do not raise the standard of life, of comfort and of efficiency of our population, and to accomplish these things we must lay out and develop the land with these as the main purposes in view.

If we desire to increase wealth, we must apply scientific principles to the planning of the future growth of our cities, towns, villages, rural townships and metropolitan regions comprising portions of each,—so as to increase the productive use of land, lessen the burden of taxation caused by unproductive utilities, create better facilities for carrying on industries (including improved methods of transportation) and promote public health and more agreeable conditions of life for the citizens.

The art of city, town and rural planning is in its infancy, and the scientific data required to afford guidance to the planner is very inadequate. Whatever need there may be for planning, the greater need at the moment is the determination of the right principles on which planning should be carried out and the discovery of the rational order of things to be dealt with in the plan. In other words, city and town planning has to follow the true logical order, and be developed to a greater extent as a science before it can take its rightful place as an art. Investigation, by means of observation and experiment, to discover facts and their mutual relations, must precede all creative work in connection with any reform of our social conditions.

Character of Suitable Areas

We must have a constructive social outlook to which to work, and acquire adequate knowledge of the underlying conditions on which to build up our plans before we start to prepare them. The objective we should aim to reach is the development of a healthy and efficient social and industrial organization which will give us the maximum of production coupled with the highest degree of equality of opportunity. With regard to the methods of acquiring knowledge, we must recognize that we have to deal with a combination of physical and social conditions that overlap at every point. We have to make a survey of both these sets of conditions, and before we do so we must determine the character of the areas that are best adapted both for the preliminary study and for subsequent plans.

Our political units are divided into three main groups, —national, provincial or state, and local. These divisions are arbitrary and are not always best adapted for planning. For instance, in the Niagara region, the planning of future industrial growth is international, in Kansas it is inter-state, and in nearly every city it is inter-municipal or metropolitan.

Manufacturing industry is ceasing less and less to be influenced by city boundaries, and on the other hand the necessary relationship between manufacture and agriculture compels attention to the overlapping problems on both sides of the boundaries of every city and town and creates regional problems. Perhaps the worst housing problem in America is to be found in the "buffer" area, or "no man's land," that lies just over the boundaries of the cities. Something must be done to bring about the co-operative action of adjacent local authorities to deal with this problem.

To plan properly and control industrial and residential areas we have, therefore, to introduce a new geographical unit, namely, the regional area. The Niagara district is such an area, so also are the metropolitan areas of Greater London, Greater New York, Greater Montreal and Greater Boston. The study and comprehensive planning of these regional areas is one of the most pressing of our social needs, and should precede the planning of the local incorporated areas within them.

The division of areas might be given as: (1) National or federal; (2) provincial or state; (3) regional, i.e. any combination of incorporated local areas, or parts of such areas, forming an industrial region; (4) incorporated local (urban or rural), e.g. city, town, village or county area.

National and Provincial Plans

What has been called "nation planning" is incomprehensible in the sense in which we use the term "city planning." You cannot plan a nation, nor yet a state or province in any detail. But there are certain things both in the nation and state or province that should be dealt with from the comprehensive point of view of a central authority.

It should be a rule never to do anything by a centralized form of government that can be efficiently dealt with by a local form of government. The local government authority in a free commonwealth should have the maximum of power and responsibility consistent with efficiency. Granted that this is true, we recognize that the sphere for national or state planning must be very limited. The character and scope of the national operations will depend on the character and scope of the national jurisdiction.

In Canada the federal government has different powers and duties from those of the federal government of the United States, and what I have to say in respect of the former will not apply in detail to the latter,—although the general principles will be applicable to both.

The question may be asked whether the limited scope of planning available to our federal and state or provincial governments is not amply provided for in our political organization. The answer is in the affirmative, so far as power to deal with the matter is concerned. In the exercise of that power, however, the political measures of our central governments in relation to the development of land are not directed with proper care towards the object of the public welfare and are not preceded to a sufficient extent by scientific investigation.

Limits of Governmental Knowledge

This does not question the intentions of governments, but indicates their self-imposed limits of knowledge of the problem as a comprehensive whole.

We have good departmental heads, and experts are employed under them to investigate social problems in compartments within the powers granted by political parties. But too frequently we introduce political measures, and set up administrative machinery to deal with social problems on the basis of isolated examples instead of on the basis of scientific investigation of facts and conditions.

The function of the federal government should be to investigate the broad national aspects of the problems of land development, industrial location, health and transportation. We have our departments available to deal with these prob-

*Excerpts from paper read November 14th, 1919, before the American Society for Municipal Improvements, at New Orleans, La.

lems but more co-ordination and constructive planning is needed. The four things that come directly within the purview of the federal government are:—

(1) Preparation of topographical maps; (2) waterways, railways and main highways; (3) subdivision of areas in undeveloped territory, and land settlement in connection with such areas; (4) co-ordination of provincial schemes of land settlement, railway extension and highway improvement.

Need for Topographical Maps

We greatly need accurate topographical maps in Canada. The gain to local authorities by having such maps would be enormous. Every structure, field and fence and the physical conditions and levels of the land have been accurately mapped in Britain. The result is that local authorities are saved the expense of local surveys to ascertain existing conditions, and to enable them to carry out local improvements economically. Only national governments can adequately undertake that work. Canada and the United States are so large and scattered that the preparation of complete topographical maps could only be undertaken gradually, but it should be undertaken in respect of large extents of area—especially those that are well populated—without delay.

We have effective means of controlling the working of our waterways and railways, but no constructive policy of directing new extensions as a part of a national scheme of development. The interest of the community needs to be safeguarded to a greater extent in connection with the planning of railway enterprises.

We are giving large sums from our federal government for highway construction, but need to keep in mind that the chief interest of the federal government in good roads is in co-ordinating and assisting the provincial schemes of main highways so as to form the skeleton of a national scheme.

The federal government has a direct interest in controlling water powers and directing commerce, and, therefore, in the establishment of new centres of industry. In Canada it owns large sections of unorganized territory and is responsible for the planning of that territory for settlement. In its control of immigration it should have regard to future development according to plans as well as to existing needs.

Scope of Federal Planning

In federal planning we should deal only with the applications of definite principles to matters affecting the country as a whole, such as those I have mentioned. In state or provincial matters the federal authorities should, by consent, help to co-ordinate state functions and schemes, and always be available as a fountain-head of expert advice. To enable it to discharge that duty we need national surveys of existing conditions, such as were advocated in the United States by the Country Life Commission of the late President Roosevelt, and these surveys should include accurate topographical maps on a workable scale.

There should be set up a federal bureau of planning and development to carry out investigations and provide co-ordinating and advisory services. Only such a body could afford to subsidize investigations that go beyond what is of immediate practical utility, and only a government that will go beyond that stage will accomplish greater progress than other governments. In the domain of physical science little progress would have been made if men like Newton had restricted their work to what was of immediate practical utility; but still the "practical" man fails to see that he is deriving his success from the scientific work of those former days and only in a lesser degree from his own organizing ability.

The planning of the state or province follows the general lines of the planning of the nation. It does not get down to details, and should not interfere with local discretion. In all matters already referred to, it can supplement the work of the nation. It should have its state or provincial bureau to act in concert with the federal bureau in preparing topographical maps and surveys; planning waterway, railway and highway extensions and deviations; and planning new territory for permanent settlement. It must, however, go further, without encroaching on the rights of incorporated local authorities.

The state or province is the legislative authority in connection with matters of dispute between municipalities. In Canada the province is the court of appeal in connection with extensions of municipal boundaries. Again, when the rights of owners of property come in conflict with public or local government rights, the power of settlement rests with the state. To develop a proper town-planning policy, you must have co-operation between adjacent local authorities; means of bringing together urban and rural authorities to control properly the "buffer" areas between them; and means of maintaining a balance, in the interests of public welfare and freedom of contracts, between public and private interests in property. Here the power and value of the state or province are supreme.

Moreover, the application of a uniform code of by-laws or ordinances in regard to city and country planning is essential and can only be achieved by state legislation. Subject to state or provincial planning laws that determine the procedure and general principles to be followed in local schemes, especially in regard to the matters of over-lapping jurisdiction and rights of eminent domain, the power of the municipality should be supreme.

Regional and Town Planning

The federal bureau, as an advisory body and the directing agency in regard to topographical maps and inter-state or interprovincial means of communication, and the state or provincial planning and development boards operating under state or provincial planning laws to co-ordinate local schemes and regulate legal procedure, give us the centralized machinery we need. To be effective, each such machine would have to include a skilled director of planning and development to give his whole time to administration, and especially to give aid to the councils of the smaller local authorities.

We now come to consider the local work and machinery, and this brings us in contact with the real work of planning, which must always be dealt with by the local unit of administration. The local units will be incorporated areas except where regional schemes are necessary, and the surveying and planning of areas must be dealt with by joint boards representative of adjacent incorporated areas, in co-operation with the several local councils within the region.

As an example I might cite the regional area comprising five cities and towns known as the Border Cities and a portion of a country area in southwestern Ontario. These cities and towns are growing up side by side, serving the same industrial needs; unable to deal effectively with their public utilities except by co-operation; having a system of transportation and natural conditions that disregard incorporated boundaries; and all lacking control over the sanitary and industrial conditions overflowing their boundaries.

Essex Border Utilities Commission

The best way to illustrate the respective character of regional and town planning schemes is to describe the kind of scheme suggested by the Federal Office of Town Planning for this area. These five authorities have a Border Cities Utilities Commission which exercises some control over their public services. It is proposed that this commission should prepare a regional survey and plan for an area comprising the whole areas of the five cities and towns, and such part of the rural area outside as may be affected by their future growth. This regional survey and map would provide an exhibit of all existing conditions—physical, industrial, means of communication, buildings, local improvements, land values, etc. We thus get the essential foundation on which to plan.

The commission, having secured the survey and map, goes further and suggests the skeleton plan for dealing with the future growth of industry, transportation, residences, park areas, etc. This is only a tentative and skeleton plan of the region and is confined to main features which are common to the six authorities. It binds no one authority and conforms to no definite legal requirement.

When the regional survey and plan is completed, the next step has to be taken by each of the local councils. These

will have before them the town-planning laws of the province, setting out the procedure and confirming the necessary powers to secure proper sanitary conditions, convenience in relation to streets, and air space around buildings; and laying down the legal procedure. They will also have the regional plan, giving accurate details of existing conditions and indicating the matters that affect the neighboring authorities. On this basis, and with this information, they can proceed to prepare a detailed plan for each of their several areas, covering all matters they regard as necessary and special to themselves.

That is one variety of regional planning. There are many other varieties. There are cases like Calgary, Alta., where the city has an area of 24,000 acres for a city of 60,000 people. Here the regional plan is restricted to the incorporated city area, and within it provision is made for industrial, residential and agricultural development. Assessment is graded to suit the different purposes for which land can be used, and public utilities are confined to the parts of the area to be built upon before other parts are permitted to be developed.

The Niagara region is much greater in size and covers all the area in both Canada and the United States affected by the industrial development contingent on the power facilities obtained from Niagara Falls.

Coal mining areas are suitable for regional planning.

We thus see that the regional survey and skeleton plan must precede the city or town plan to get satisfactory schemes carried out.

This paper is of necessity a brief and general introduction to a great subject. It deals with only the outline of the principles that need attention to get more desirable forms of administration and control of land development. One or two arguments in favor of the co-operative action of municipalities under central guidance may be given in conclusion.

We are face to face with the fact that established industries all over this continent are leaving the cities and migrating to semi-rural districts, and that new plants are being erected to a greater extent in the semi-rural areas than in the crowded centres of cities. This tendency suggests two things:—

Frst, that the cities which are losing their industries and revenues should consider how to prevent future disintegration; and second, how to plan the suburban development around cities so as to prevent the recurrence of evils that have caused the dispersal of industries from the existing centres.

Industrial Centres Becoming Congested

It is largely a matter of land development, as the causes of the dispersal are associated with the dearness of land, the opportunities for expansion at reasonable cost, the facilities for transportation over the land, and the planning of residential areas suitable for housing close to the plants.

The proper control of land development is needed to prevent undue density of building in parts of our cities and undue scattering of buildings in other parts. Congestion has reached a point in most large cities where it has become impossible to carry on business with dispatch and efficiency, and where public utilities are strained beyond their capacity and causing severe losses to local authorities.

The scattering of residences and factories over our suburban areas, with the greater intervening areas of vacant lots, served by unproductive public utilities, has the same effect from a different set of causes. As cities grow, the costs of administration increase instead of decrease; transportation, while becoming more centralized, instead of being more economical, becomes more costly; and all the advantages of better sanitary conditions are lost because of lack of air space around the buildings.

The growing cost of food is not entirely due to war conditions. It is partly caused by the growing tendency to divide the city from the country and to create a cleavage between them as if their interests were not dependent on co-operation between the two. One of the biggest blunders on the American continent has been the encouragement of a system of land speculation that has sterilized the use of land in the suburbs of our cities. Tens of thousands of acres are lying idle waiting for buildings that will not come for generations, and producing no food at the door of the consumers.

These conditions need urgent attention if for no other reason than that most of our cities and towns are facing financial problems that will tax the wit of man to solve in the near future. Altering of the system of taxation will have no permanent effect if we do not control the development of land and the social forces of industry by adequate and comprehensive schemes of planning.

Summary

1. All land should be planned with the definite object of securing health, convenience and amenity in connection with industry and residence, and not for any object of speculation.

2. Scientific investigation of regions and municipal areas should precede the preparation of city and country planning schemes. We need to know more of the facts and their mutual relations before we employ the art of the regional or city planner.

3. The division of areas requiring consideration are: (1) National or federal; (2) provincial or state; (3) regional; (4) incorporated local.

4. National surveys and plans should deal with broad national and state aspects of development, such as preparation of topographical maps; planning of waterways, railways and national and state highways; and co-ordination of provincial or state schemes. The national organization should be largely advisory. The state scheme should supplement the federal schemes, and state law should set forth the procedure to be followed in connection with schemes for regional areas and incorporated local areas, and make provision for co-operation of adjacent municipalities and for dealing with conflicting public and private interests in property. A state or provincial planning and development board should be formed in each state or province.

5. Many industrial, mining and other areas are growing up without regard to incorporated boundaries and need to be surveyed and planned in regional units by co-operative action of the several authorities within them. Surveys and skeleton plans of these regions should be prepared in advance of city or town-planning schemes. A joint board, representative of the local authorities, should prepare the regional survey and skeleton plan.

6. The definite detailed plan should be prepared only by the incorporated local authorities, subject to consideration of the broad national and state aspects of the problem and to the regional aspects and conditions as revealed by the regional survey and plan. This local plan should fix the industrial and residential zones; deal with sanitary provisions, air space, convenience, local problems of transportation and amenity; and anticipate future growth for forty or fifty years. A local board, or commission, should give constant study to the planning of the incorporated area and to the execution of the plan, subject to control of the expenditure by the elected council having jurisdiction over the area.

7. Finally, the solution of our social problems and the proper development of our municipal improvements cannot be obtained by the mere art of planning, but by scientific investigation followed by plans based on sound economic principles and prepared with due regard to the ideals that should inspire every community that seeks to follow the path of real progress.

According to a report made recently to the city council of Peterboro, Ont., $116,618 has been spent to date on the Hunter street bridge, which is now being constructed.

Toronto's citizens will vote January 1st on the by-law providing for the guarantee of $4,328,665, Toronto's share of the $8,360,794 which the "Hydro" radial from Toronto to Bowmanville will cost according to the estimates made by the Hydro-Electric Power Commission of Ontario.

SANITATION AND MUNICIPAL DEATH RATES*

By George A. Soper
Major, Sanitary Corps, United States Army

BY sanitation is meant that branch of systematic health work which requires plant and a force to maintain it. Examples are works for the procurement and distribution of wholesome drinking water; the collection and disposal of liquid sewage; and the gathering and final disposition of kitchen waste, ashes and other discarded material. These are obviously sanitary undertakings but the list of improvements which go to make a city sanitary does not end here. Broad, well-paved market places; suitable playgrounds; bright, well ventilated schoolhouses; in short, whatever the city has in the way of plant which goes to prevent the injuries to health which result from too densely segregated masses of people, might properly be comprised under the head of sanitation; but in everyday parlance they are not so included.

Sanitation and Disease

Yielding to works of sanitation are not only typhoid, dysentery and other diarrheal diseases, but many other forms of sickness. To introduce a public supply of pure water in place of a polluted one, or to build sewerage in a town which has had no good way of disposing of excrement, is to reduce the prevalence of nearly every disease from which men suffer and die. Nothing that can be done is so certain to lessen the death rate.

Sanitary works possess a number of advantages as compared with other measures for the prevention of disease. For one thing, they do not require as high a degree of skill in their administration as do boards of health. For another, they have an advantage over personal precautions in not being individual in application and unco-ordinated in action. Sanitary works have a wholesome application. A water supply which is pure is wholesome for every person who has occasion to use it. The street that is well paved and kept clean is of advantage to every one who travels over it by vehicle or foot. And sanitary works do not hide their merits under a bushel. Their good effects are in plain sight —a constant recommendation of the good sense of those who are responsible for the welfare of the community.

Beginning of Municipal Sanitation

From the first, sanitation has been a feature of many American cities. Sanitation, although long delayed, when it came, came like a revolution to the continental cities of Europe. The beginnings of municipal sanitation everywhere are due to European initiative. Public water supplies, as we know them to-day, and sewers to carry away the most offensive and dangerous part of a city's filth, are recent European contrivances. Street lighting, good pavements, adequate transportation, tenement house reforms, the construction of parks and playgrounds, the regulation of vehicular travel and street paving and cleaning have been developed more recently. The American city which ignores foreign practice in these directions fails to take account of experience which can save it a great deal of money.

The sanitary regeneration which European cities have experienced has had no counterpart in the United States. There has been no necessity for such revolutionary changes. American cities were small when the world began to learn that sanitation was an indispensable feature of every municipality. There was never such over-crowding, such slums to clean, such foci of filth to clear up and eliminate, as existed abroad half a century ago. In 1860 there were only 16 cities in the United States with a population of 50,000 or more, as against 148 in Europe.

Municipal Growth in America

The significant feature of municipal growth in America as compared with that in Europe has been less the reconstruction of cities already large than the construction of a great number of small cities. Hundreds of these have passed and are now passing through their periods of infancy, youth and adolescense toward a maturity which foreign cities attained long ago. Their sanitation takes place as they grow.

Water Supply Comes First

The first important sanitary improvement to be made in the growing village is the public water supply. This leads to the use of water closets and, to accommodate the drainage from these, cess-pools are built. The privies, the original provision for the disposal of excrement, are then eliminated. Street pavements are presently considered and the cleaning of the pavement and the collection of house refuse by municipal effort follow. At first garbage is collected by scavengers at the private expense of the householders; later it is done at public expense. The young city may now be said to have passed through its period of infancy and entered that of youth.

A sewerage system is built later in the city's growth. During this period the houses are gradually built closer to one another and in a more permanent form of construction until they stand in a compact mass. More attention is given now to pavements and to the cleaning of them. Parks are laid out, lighting is improved, ordinances are passed regulating many sanitary matters. The city has now reached its period of adolescence.

The period of maturity, that is, the period in which civic responsibility begins fully to express itself, comes last. The regulation of building construction, the control of traffic and the adoption of far-sighted plans to insure public health and safety are often taken up at this time. They should have been considered at a much earlier period.

Business Men the Leaders

It is instructive to observe how often it is that a community owes its sanitary improvements to its business men. It might be supposed that the principles of sanitation were more within the grasp of professional men than of those whose attention was chiefly occupied with manufacture and trade, and that doctors and lawyers and ministers would be foremost to see that the health and welfare of the public were properly looked after. This is not, however, always the fact. There is no disposition to belittle the help which professional men can give, but an experience in public work which covers many years and extends over many cities and states shows that when it comes to municipal improvements, it is the commercial element which usually exercises both the initiating and sustaining influence.

The explanation of this is simple enough. The general subject of sanitation is not so complicated as to be the exclusive province of any class or profession. Certainly the need of sanitation and the benefits of it can be understood by every intelligent person. Business men are accustomed to weigh returns against expenditures and readily appreciate that sanitation is a sound investment. Moreover, they are accustomed to action and when they get together to obtain action for the public welfare they are apt to get it.

Technical Advice is Essential

Often the important thing to know is what to do in order to improve the sanitation of a city. Why is the death rate high? What should be done to reduce it under the particular circumstances which exist? In answering these questions many technical and financial details may have to be considered. This is properly the work of experts. An unprejudiced expert should be called on to make a report based on a study of the local situation and on a knowledge of what other cities have done and are doing under similar circumstances. This report should serve as a program behind which the solid, common sense of the municipality can array itself.

When a city needs a health program, as every city does, the best way to get it is for the business men to demand it of the municipal administration through their commercial organizations. If the municipality does not possess the talent for the work, an expert should be called in from out-

*From a paper presented at the second Pan-American Commercial Conference.

side. In many cases commercial organizations have themselves employed experts to make investigations and reports to serve as a guide to the citizens in demanding what is proper.

Health Should Determine Appropriations

The question is often asked, what can a city afford to spend for sanitation? The answer is that it can afford to spend whatever is necessary in order to make it healthy. If it is already healthy, it need spend but little; if it is unhealthy, it must, of course, spend more. A city, like a man, must have health if it is fully to realize its possibilities. Epidemics paralyze business, and a high death rate is a reflection upon the good business sense of a community. In many cases, investments for sanitation should be looked upon as policies.

Every city and every village ought to have a program of development, a plan to which to build, a settled scheme of construction to which to refer details. This program should be prepared early in order to keep the growth properly proportioned and prevent the excessive development of some relatively unimportant features at the sacrifice of the essential. Paramount in such a scheme should be suitable provisions for health.

Maintenance Charges Not Excessive

Although a considerable investment of capital has to be put into sanitary works, the maintenance charges are not excessive as compared with the administrative costs of hand labor, which is often used as a substitute to accomplish the same result. It must not be expected, however, that good sanitary works can be built or that they can be effectively operated without care. Skill and attention in design and construction and operation are indispensable to the best results.

Among the 219 cities of 30,000 or more population in the United States, for every $10 put out each year for all purposes of administrative effort, $1.10 on the average is expended for health and sanitation. The amount varies among the different cities, according to the natural advantages of the site with reference to water supply, drainage, kind of population and commercial and industrial conditions, and according to th foresight and business ability with which the work is planned and carried out. The percentage of the total yearly expenditure which is devoted to health and sanitation sometimes runs as high as twice the figure stated, and occasionally falls to about one-half of it. The size of the city does not affect the percentage.

The Provincial Builders and Supply Association of Ontario will hold its next annual meeting during the first week of February. The president of the Association is Herbert Elgie, Toronto.

The 1919 membership drive, which will be held by the American Association of Engineers during the first two weeks in December, has as its slogan "10,000 members in 13 days." All of the 90 clubs and chapters of the association are making final arrangements for the drive. Never in the history of engineering organizations has anyone ever before proposed such a great increase in membership within such a brief period.

The Associated Manufacturers of Water Purifying Equipment has now become a permanent organization, and will hold a meeting this month in Omaha, Neb. Although the organization was primarily formed for the purpose of securing necessary priority orders during the war, it will now continue largely for the purpose of taking up work in standardization of equipment sizes, of guarantees to customers and of terms of sales. The officers of the association are: Chairman, F. B. Leopold, Pittsburgh Filter Mfg. Co.; vice-chairman, Arthur M. Crane, New York Continental Jewell Filtration Co.; secretary, H. G. Tate, Borromite Co. of America.

WIDENING RADIUS FOR ELECTRIC POWER*

Transmission Over Lines Exceeding Three Hundred Miles Is Now Commercially Feasible at 220,000 Volts, Making Distant Waterfalls More Valuable

RECENT achievements are increasing the distances of economical transmission of electric energy. In long-distance transmission of electricity high pressures or voltages are required—the higher the voltage, the lower the losses. For several years after long-distance transmission had been introduced, it was the practice to allow a pressure of approximately 1,000 volts per mile. It was found, however, particularly with distances of over 100 miles, that the distance allowed could be increased to as much as two miles per 1,000 volts. In other words, lines operating at about 100,000 volts pressure have been transmitting energy over distances exceeding 200 miles. More recently, lines operating at 150,000 volts have demonstrated their practicability; one of these has been in successful operation for over five years.

Now electrical engineers are of the opinion that pressures of 220,000 volts are quite feasible, and it is stated that "the handling of electrical potentials of 220,000 volts does not appear to involve any disturbing complications or uncertainties. In fact, the manufacturers do not recognize that any serious problem exists. Current design principles and materials now in ordinary use will be employed, the principal difference from present high voltage equipment being the greater amounts of insulation and the larger clearances required. The step to 220,000 volts is relatively no greater than that previously taken from 66,000 volts to 110,000 volts or from 110,000 volts to 150,000 volts. Certain of the manufacturers have already developed designs, and assert readiness to undertake the commercial production of 220,000-volt equipment on short notice."

The advantages of long-distance transmission are of particular interest to Canada, where much of our water-power is found in large units, and, to reach many consumers, it may be necessary to transmit the energy for a considerable distance. It is perhaps of greatest interest in connection with our abundant water-powers in the River St. Lawrence and in the area lying to the north of the settled regions of the prairie provinces. It brings us closer to the possibility of making these vast stores of energy available within the settled portions.

In Saskatchewan, for instance, the power sites of the Churchill river are only some 250 miles from Saskatoon and 350 miles from Regina. The transmission of energy over these distances would be quite feasible at 220,000 volts, and economically possible when the demand of the entire district reaches a high enough figure.

*From "Conservation."

Armstrong Bros. Tool Co., of Chicago, are making extensive additions to their plant, buildings and equipment. The new buildings include an addition to the drop forge department, a new building for the hardening and heat treating department, and a new reinforced concrete building for the general office, finished stock and shipping department.

Among the speakers on the program for the Great Waterways Conference, which was held last Tuesday and Wednesday, November 18th and 19th, at Windsor, Ont., were E. L. Cousins, chief engineer and general manager of the Toronto Harbor Commission; Sir Adam Beck; and W. M. German, of Welland. Mr. Cousins was scheduled to speak upon the canalization of the St. Lawrence River and what it means to Great Lakes points. The subject of Mr. German's address was "Enlargement of the Canal System Between Lake Ontario and Montreal." O. E. Fleming and Alex. Simmers were expected to lead a discussion upon the advisability of forming a Canadian Inland Waterways Association.

TOWN PLANNING, WITH SPECIAL REFERENCE TO OTTAWA

By Noulan Cauchon
Consulting Engineer and Town Planner, Ottawa

(Continued from last week's issue)

It is the intention that both sides of the Rideau river and the Rideau canal shall be a parkway extending out beyond the limits of the city. That is coming; it is simply a question of time. The Rideau canal property is government property; it has been handed over to the Ottawa Improvement Commission with a view to their improving it so far as their funds will allow. Unfortunately the funds are largely tied up in fixed charges, so we cannot expect very much new work until the government helps us. Of course, I am looking at this thing not so much from the local point of view; if this city is to be worthy of being the capital of Canada, any accomplishments in that direction should be the result of the effort of the whole country. As a matter of fact, the only thing here that is truly "capital" is the Parliament Buildings site; on those grounds you cannot run in and do anything without the Dominion police nabbing you. Theoretically, then, the capital is confined to the Parliament grounds and the federal property along the canal.

Dominion Park near Ottawa

There is a very fine mountain range north of the city and not far from it. It was suggested some years ago by Mr. Macoun that this be made a Dominion Park, and that is a splendid suggestion; it is incorporated in the "plan." If that was made a Dominion Park like Banff, people could live there, under proper restrictions, because it is brought right to the door of the city.

I have advocated that the railroads, after they pass through the tunnel, should take the river's edge and eliminate also the barrier which in time will grow up on the present Canadian Pacific Railway tracks. Because that may be ten, fifteen or twenty years off is no reason why this trackage sheuld be left there until it becomes just as objectionable as any other of its kind. The general principle is this: Whatever your barriers may be, you have to go across them or underneath them or over them; get as many of them together as you can, therefore, and thus simplify the problem of dealing with them.

I do not admit that a railway cannot be made a thing of beauty. A proper railway embankment, well planted and kept in good order, carrying the passengers along where they can see the scenery, is just as much a contribution to beautification as is a great boulevard. Why do we build paved roads all over the country? We have visitors who come here who are fortunate enough to be able to ride around in automobiles and see our beautiful parks. But why should we not enable the thousands who travel in trains to get the same impression of this country, of this city, or of any city in America? Why should the only impression we give the stranger who travels on trains be the one that he receives from looking at our back yards and clothes lines? I want the railway to be on a boulevard, so that the thousands of people who travel here on trains will get the same impression as the man who is fortunate enough to be able to go round and view the scenery in an automobile.

Scenery for Railway Passengers

I was in Niagara Falls, N.Y., the other day, at the invitation of the Chamber of Commerce, and I was talking with some of the members of the Michigan Central line on the Canadian side, at Falls View. I said: "By all means preserve that view for the train." They thought it rather funny, and I said, "More people will travel in trains over that line than ever travel on your roads; by all means let the railroads exhibit to the passengers as many of the beauties of Niagara Falls as possible." We make beautiful railway coaches, do we not? I am interested in this because it seems to be ingrained in the public mind that a railroad is something that is objectionable. I repeat that in principle it is one of the finest things we have; it is simply a matter of treating it properly.

The question of industrial development in Ottawa is a big one. A good many people have the idea that you cannot have industrial development and still keep the city a beautiful place to live in. I think that is another popular fallacy. You cannot have a house without a kitchen, and the kitchen is just as useful and may be just as beautiful as the parlor. But if you put the kitchen stove in the parlor and the piano in the kitchen, you have the mix-up that is characteristic of most of our cities in their civic housekeeping. It is exemplified here just as it is elsewhere. Any professor of physics will tell you that the prevailing winds on the northern half of this continent are from the west and northwest; therefore put your industrial development on the east side of your cities. I tried once or twice to reform the world, but it didn't work as fast as I thought it might. However, perhaps it is a matter of time.

Residential and Industrial City

There is nothing to prevent the development of the capital on perfect lines as a residence city and also on perfect lines as an industrial city, provided each is put in its proper place. You cannot get along without industries; they are the maintenance of life; they are the sinews of life; but they should be put in the right place.

My proposal is that all the industries should be east of the city. Of course, the question of local transportation comes in; there is the question of the canal. I got into the same trouble here a few years ago that I got into at Niagara Falls by telling the Chamber of Commerce this: "I do not know what your opinion of small canals is, but my opinion of the small canal is that anything that will not carry an eight or ten thousand ton boat is an economic absurdity."

The Buffalo papers put a two-column heading over the statement of mine that the Erie canal ought to be turned to account as an irrigation ditch. I don't know whom they were hitting at, but it is a fact that canals are an economic absurdity if they are not deep water canals and cannot carry heavy tonnage.

The Rideau canal is a beautiful streak of water through the city, but it is nothing but an open sewer, and I am in favor of removing it. I would like to see the bed of the canal used for a fast radial railroad, so that people could get from the country into the heart of the city in as few minutes as possible. The average time a man will take to go to his work is half an hour—or perhaps I should say the maximum time, for if he is faced with the alternative of living more than half an hour away from his work he will, as a matter of psychology, accept objectionable conditions in the city rather than do that. So the greater the extent to which you can get your people out of the centre of the city and into the surrounding districts within half an hour, the greater will be the area of land made available for homes.

Reducing the Home's Overhead

The great principle that we are seeking in this matter of town planning is to keep down the capitalization of the home. I believe the time will come when the providing of housing will not be, as it is now, an emergency proposition; I believe that it will be the proper function of civic government to provide houses at cost. In other words, all increment will be cut out. You can tax a man in proportion to the money that he is making, but you should not diminish the efficiency of the home. You should not much tax that which is non-productive; it seems to me that that is plain common sense. You should eliminate all taxation possible from the home.

In many cities in Canada the business area, the earning section, is very much under-assessed as compared with the homes. In fact, any laxity in assessment upon the business or earning propositions is naturally going to be doubled back upon the homes. The tax rate is limited by law, and when they get to the limit and find that they need still greater revenue, they raise the assessment. But assessment should be applicable relatively only to productive sources.

The only source of wealth is production—work; you can't take taxes out of a churn like butter; they have to be produced each year, and if you pound them out of the home you reduce the individual and national efficiency.

There is the question of the plaza, or the civic centre. Personally I favor a large, somewhat triangular centre which would couple up with the parliament grounds and give us a large open space; but the development pictured on the plan, built on great piers, would be rather costly. My proposal is that the through railroad tracks should go down on the west side of the canal to the tunnel under Wellington street south of the post office. In the Commission's plan which was submitted to the government, the tracks go through the bottom of the station, circle through the foundations of the plaza and go into the tunnel at the north side of the post office.

Going on the north side instead of the south side does not affect the post office, but going through under the station and under the plaza, means that you cannot have a clearance for your boats in the canal. A 33-ft. clearance is required, and the proposal involved in this is to start from the third lock and carry that canal through in a great canyon, rebuilding the locks a good deal south of the station. This involves a difference in cost of from two to four million dollars, that is all!—just enough to block an ordinary scheme. A few millions does not count in war time, but when you come to get it from a government or city council in time of peace, it is quite a different matter.

The tunnel proposal, I think, has been accepted by everybody. Those who think that a railroad is objectionable could wish it in no better place than underground, so they could not complain if that were done.

Criticism of Public Buildings

There is the question of the great public buildings here, the parliament buildings. The proposals so far submitted to the government for any disposition of ground along Wellington street do not seem satisfactory; it has been acknowledged that the plans which were earlier submitted were not satisfactory. One thing that I have pointed out is that the heating plant for the new parliament buildings has been placed in the centre of the area previously set aside for the new departmental buildings. Without going into the economics of putting your heating plant 3,000 ft. away from the building which is to be heated, how they are going to disguise the chimney I do not know; personally, I would blow it down without a moment's hesitation. No architect nor anybody else has a right to put his heating plant plunk in the middle of what we had hoped, and understood, to be the site in the future of a great set of departmental buildings. A chimney out of place is not a thing of beauty.

The plans of the proposed public buildings, therefore contain certain things which are not up to date. Those who have studied "sunlight engineering," as it is coming to be called, know that it is essential to health and efficiency that sunlight should penetrate at some time of the day to the base of all walls and into rooms. Here is one of the finest sites in America. Buildings are proposed here with triangular courts to the base of which the sun could not reach by any kink in the zenith. The building that the government recently put up on Queen street—I have been told that it is modelled after something up to date in Chicago or somewhere else—contains a well into which the sun cannot penetrate. This well is said to be 100 by about 50 ft. But the size is not the point; I do not care how big it is; if the sun does not go to the bottom, it is not right.

Sunlight and Office Buildings

I urged in the first place that the building be not put where it is. It was the first public building which had been put up after the submission of the plans and should be in all respects an integral part of a larger plan; and I submitted that if it was not erected on Wellington street it should at least be on Sussex street. That was my first objection; the other point of view was this: I said, "If you will not put the building anywhere else, at least open up the south side of it into a court so that the sun will penetrate into it." They did not do it; they thought it was not economical. I say that in the long run they will find that it is far from being economical to exclude the sunlight. The rays of the sun are the ultimate source of all energy on this planet. The sun is the principle of life, and if you keep it out of your buildings, I care not whether you pave them with marble or roof them with gold like the Buddhist temples, the occupants will suffer.

To the extent that sunlight is excluded, to that extent the people will be less efficient and have less vitality. There are fundamental principles of organic life; you cannot twist them or avoid them by any process of imagination or architecture or engineering or anything else. No up-to-date business enterprise would accept plans excluding sunlight from the buildings proposed to be erected. Why should we in Canada accept in public buildings a condition which is absolutely antediluvian?

Architecture of Parliament Buildings

Another point of discussion in connection with the capital is the question of architecture. Our dominating feature here is the parliament building. Originally it is in Gothic—Victorian Gothic, if you will, but whatever may be its defects that is the keynote that was given to our development. You cannot come along and make your other buildings overshadow or overpower these; if you do, you will subsequently have to replace them for something which will be in harmony—either that, or you are going to spoil your scheme.

I do not mean to say that thirteenth century Gothic should be followed in a departmental building. A Minister of the Crown, discussing the matter with me some years ago, said: "I do not like Gothic. My office is as dark as a tomb; I want some kind of architecture that will give me light." I said: "There is no architecture in the world that involves as little wall space as Gothic, if you take the right kind of Gothic." Because somebody, in the exercise of his judgment—or in his lack of judgment, I should say—chose for office buildings a style of Gothic that has the smallest possible window space, does not mean to say that Gothic is not a good style of architecture for light; it is the greatest light architecture in the world if you get the right style. It is not adaptable for office buildings as a general rule, but it is adaptable for great buildings such as are required for the Senate and the House of Commons.

My criticism of the new buildings is this: Gothic is essentially a development of functional parts joined together. That is what is lacking in our buildings here. The functional parts, like the parts of a great cathedral or an ancient castle, are not expressed. The mildest criticism of the whole thing as a matter of principle is that it is a Renaissance plan with a Gothic shirt—and pockets in the shirt. The proper expression of the spirit of Gothic lies in the expression of the functional properties of the building; you cannot cloud these and still have a good Gothic building. A very fine detail will not redeem a bad plan; that is to say, beautiful Gothic detail will not make a Renaissance building a good Gothic building.

Plan Commission Appointed

A few days ago I saw a copy of an order-in-council which has remedied, in principle at least, a great defect which has existed in respect to the submission of plans for the improvement of Ottawa. Plans are made; sometimes they are accepted and sometimes they are not; but even if they are accepted they are put in a pigeon-hole and left there; and when a man wants to build something which is in contravention of that plan, there is nobody to hit him promptly on the head with a club. That is exactly what happened in the case of the office building that I have referred to; there was nobody whose particular business it was to keep alive the spirit of the plans which had been submitted. This order-in-council names three gentlemen as a commission to look after that very thing: David Ewart, consulting architect to the government; R. C. Wright, chief architect, Public Works Department; and Thomas Adams, town planning adviser to the Commission of Conservation and to the Dominion Cabinet.

I hope, therefore, that we shall make progress towards the preservation and employment of what is good in the

plan; we have now a body to which we can go and make suggestions, and I am sure that they will get a sympathetic hearing. I hope it will be their practice, as it has been the practice in connection with town planning schemes in England, to have public hearings in regard to these matters. You cannot put anything through there without the public having their way. Of course, the representations that are made are not always heeded, but opportunity is given for the ventilation of all grievances, and, after all, that is the safety valve of our democratic system of government.

THE CONTRACTOR'S SALARY AS "OVERHEAD"*

By J. F. Lidral
Of Arvesen & Lidral, General Contractors, Seattle, Wash.

THERE are many among you who have been brought up on construction work since boyhood. There are others among you who have perhaps gone to school to equip yourselves more scientifically for your life's work. In either case you have devoted long years of experience and hard work to place yourselves in a position to be able to accomplish something which the ordinary individual cannot do. You have all the marks of a profession if you will demand from the world that you be considered as professional men.

When a calling is placed in the rank of a profession, the world recognizes that the individual engaged thereip has been qualified by virtue of long study and experience and classes him as an expert who is capable of understanding and undertaking difficult problems. With this recognition comes also the inclination to be willing to compensate him in direct proportion and to the extent that he is able to save time and money for the man who engages him.

You have endeavored to build up your organization and working force. You have saved your money and paid your bills in an attempt to build up your credit standing. Why? So that you are able to perform work better and quicker and buy material cheaper than the outsider or the ordinary layman.

Now, laying aside for the moment the fact that you risk your money and reputation in your business, how much in the nature of a salary are you worth to your firm? Are you working simply for the love of work or are you worth a salary of $100, $200 or $1,000? You hire a foreman and you pay him perhaps $10 a day or approximately $250 a month. This foreman is working for you because he lacks something you possess. Either he does not possess the necessary knowledge to run his own business or his credit is gone or he possesses too much knowledge, knowing that he would be minus his $250 if he figured his worth as do some contractors. The foreman works his eight hours per day and his troubles end.

Forty Hours? Probably Eighty!

There are very few of you who limit your week's work to a minimum of 40 hours for your profession. It is more likely that you are on the job at 7.30 and spend the time until 4.30 racing like mad to keep it going. Then you go to the office until 6, trying to catch up with what you missed during the day. In the evening you have an engagement, here, for example, if you wish, or some party wishes a little free information about a building they never intend to erect, or your car needs adjusting after a hard day's abuse hauling nails and wheelbarrows, or you may go back to the office to work on the books and worry about how you are coming out on that job you took too low. Even Saturdays and Sundays are not exempt for most of you, and I'll wager that the majority of you neglect your families almost entirely. It is safe to assume that you put in more than double the time your foreman does. Is it not logical that each and every one of you is worth at least $500 to your firm? This item is just as much an overhead as is your office rent, interest on the money invested and other items. In other words, to the overhead of every firm should be added a salary for each individual engaged therein.

Some of you may not agree with me perhaps and will make the declaration that a man's compensation should come out of the profit. The definition of business is an undertaking to which risk is attached and which is attempted in order to result in a profit. Your overhead does not and cannot include a probable loss on any job. You lose money as all of you have done at different times. Your profit then is solely the necessary compensation over and above everything else to warrant your assuming the risk involved. In other words it is a bonus over and above your overhead and labor which is rightfully yours for the assumption of the undertaking.

It may be well at this point to make comment on some of the work going on this year. There is at present a noticeable shortage of carpenters and bricklayers. All are employed, indicating that there is considerable work under way. Go along any street of this city and you will see evidence of considerable building activity. How many of you contractors have a job at present that you are satisfied is bringing you all the returns to which you are entitled? There seems to be plenty, and still most of you are marking time waiting for more work to turn up at better prices.

Entitled to Fair Profit

We will take a concrete example: The one-story mill type garages, so many of which are under construction at the present time, with brick walls, concrete floor, tar and gravel roof on trusses and cold water paint on the interior. This is the simplest sort of a job to figure and yet our figures vary 100 per cent. Why? There are no slave-drivers among us nowadays. The workmen will give just about the same amount of work to all of us. Your credit, let us assume, is equally good or at most we cannot underbuy each other more than 10 per cent. There are two reasons. First, you are afraid that the other fellow is going to grab it and you cannot get over the idea that you may make a little spending money if all goes well and you are lucky. Second, you have been influenced by owners and real estate operators who convince you that such buildings have always been and are now being built for 6½ cents a cubic foot. It can't be done. You can't put in brickwork for much less than $40 and 8-in. concrete, including form work, much under $18, so what is the use and why worry about the cheap owners and architects who persuade some uninformed mortal to pack their troubles? I plead with you that in these days of plenty for all of us, you figure to come out on top, allowing for your overhead, a salary for yourself and a fair profit.

In closing, I would like to ask each one of you this question: What do you consider you are worth to the business and professional world, standing apart as one who is an expert? Not until you take enough personal pride in yourself and place a fair price on your labor will the world wake up to the fact that you deserve recognition as an expert and are entitled to a fair compensation for the time, money, experience and energy which you have devoted to your life's work.

*Excerpts from an address before the Seattle Master Builders' Association.

There are only four other communities in the world that have gone a greater distance to secure their water supply than has Winnipeg, Man.

The annual meeting of the Union of Manitoba Municipalities is being held this week in Winnipeg. One of the principal speakers will be J. G. Sullivan, on drainage.

Prominent citizens connected with the Board of Trade of Peterboro, Ont., are advocating the formation of a City Development Commission in order to prepare a plan for that city. Thomas Adams has promised his assistance if the commission be formed. James White, deputy head of the Commission of Conservation, who was in Peterboro recently, is reported as having said that Mr. Adams has been offered $100 a day to go to the United States and plan cities there, and that he feared that the commission would lose Mr. Adams' services.

THE LOGICAL CONTRACTOR*

By William S. Wollner

A CONTRACTOR was asked recently to bid upon a piece of work consisting principally of the erection of a timber truss lift bridge with the necessary foundations and approaches, the total cost of the job being estimated in the vicinity of a quarter of a million dollars. The job seemed a desirable one to the contractor and he carefully prepared his bid which he submitted to his bankers to learn if they would finance the work if he should be the successful bidder. The bankers referred him to their consulting engineer who requested him to leave his figures for a few days so that they might be checked. When the contractor returned for the engineer's decision he was told that while his bid had been carefully and accurately figured it would be useless for him to submit it as there was no chance of his being awarded the work.

The contractor was disappointed and proceeded to display his disappointment in an angry arraignment of the engineer, who also lost control of his temper and instead of explaining the reason for his statement remarked that he could even tell the name of the contractor to whom the work would be awarded. Upon the accuracy of his statement being questioned he named "Smith, Jones & Company" as the firm to whom the work would be awarded and showed the contractor the door. When the bids were opened it was found that Smith, Jones & Company were the lowest bidders for the job, their figure for doing the work being many thousands of dollars less than that of the contractor first mentioned. This man called upon the engineer, apologized for his display of anger, and remarked that if the engineer had told him that he was upon the "inside" he would not have questioned his judgment upon his previous visit. The engineer protested that he was not on the "inside" and proceeded to explain the course of reasoning that had led him to believe that Smith, Jones & Company would be the successful bidders. His explanation ran something like this:—

"In checking over the figures from which your bid was made I found that they took in every contingency that might arise; that you have very properly figured upon the safe side wherever there was a question as to what might be encountered in the course of the work. In your foundation excavation, for example, you figured the cost upon the expectation of encountering rock where there might only be mud and shale, it being of course impossible to determine this under-water condition accurately until the work was under way. Likewise, you figured upon using the extreme length of piling and upon paying the highest scale of wages.

"Another thing that I noticed was that a large proportion of your bid represented the cost of getting your outfit onto and off of the job. You have all the machinery necessary to do the work but it is located far from it and it was necessary for you to figure the freight upon it as well as the cost of getting the equipment to the site of the job and back to the railroad.

Competitors Had Strategical Advantage

"From your point of view you had figured the cost of the job properly. That is, you figured how much it would cost you to actually do the work under the worst conditions that might prevail, with a moderate margin for profit. Having assured myself of the accuracy of your figures from this viewpoint I proceeded to the next question—What would it cost someone else to do the work? In surveying the field I learned that Smith, Jones & Company were the *logical contractors* to do this work. They had done considerable work of a similar nature in the same vicinity and had in fact constructed a bridge for a railroad within a few hundred feet of the proposed structure a few years before. They did not have to back up their guess of what material would be encountered by figuring upon encountering the most difficult to handle; they knew what they would find and where they would find it. Likewise, they knew almost to a foot the length of piling that would be needed.

"Then as to wages; Smith and Jones have been working in this same territory for some years and have built up an efficient organization in which they pay the prevailing scale but from which they get a much larger return in work than you or any other contractor not similarly situated could hope to get. Further, not only do they not have to pay freight on their equipment, but as it is located further up the stream that this structure is to bridge, they have merely to float it down to the site of the work at practically no expense for transportation or loading. As they have work to do in the same vicinity when the job is finished, the cost of removing their outfit will be comparatively small.

"Thus they had the advantage over you or any other contractor who might figure on doing this particular piece of work, and I was practically certain that they would be the successful bidders. Furthermore, as the *logical contractors* for this job it was right that the work should be theirs."

As engineers sometimes become contractors and are often called upon to pass upon the bids of contractors, either as the employee of the contractor or as the engineer of the project, it is important that they understand this theory of the logical contractor. As a contractor or a contractor's engineer he should consider his position with reference to other bidders, and determine whether he is the logical contractor, and if not, whether he is willing to cut down his bid to meet the advantage that the logical contractor possesses. As a project engineer he must be certain to see that the logical contractor is not only given the opportunity to bid but that he is urged to do so in order that the project may have the advantage of the lower bid made possible by his strategic position.

Securing Advantageous Highway Bid

An illustration of how an engineer may reduce the cost of having work done by inducing contractors who are in a position to carry it on at a minimum cost bid for it was given in the recent letting of a county highway job. A road was to be built connecting "A" with "B," the construction cost, according to the engineer's estimate, being divided about evenly between grading and paving. The job was just about big enough to attract bidders from a reasonable distance but not big enough to absorb the cost of transporting a complete grading and paving outfit to and from the work without unduly adding to the expense of building the road. There were only two contractors in the vicinity of the work; one at "A," where he was grading the site for an industry, and the other at "B," where he was placing a concrete and asphalt surface on an old road for the State Highway Commission. Each of these contractors had a complete equipment for the work he was doing but was unprepared to do anything but that. The county ordinance under which the road work was to be done called for bids covering the entire job and it was therefore impossible for either contractor to bid for the portion of the work he was prepared to do.

Realizing that these men were the logical ones to do the work, the county engineer invited them to meet him in his office and pointed out to them the opportunity for combining their outfits and bidding jointly for the work. He pointed out to them that they had an advantage over other bidders in that their equipment was practically upon the job and that their forces were already organized to do the work. Being convinced, they followed his suggestion and filed a joint bid for the job which proved to be considerably less than any other offer and which saved the county a part of the cost of building the road.

Of course this engineer opened the way for charges of favoritism toward these particular contractors, but the fact that he was serving the best interests of his principal was sufficient reason for the course he took. It is the manner in which he handles matters of this kind that makes an engineer valuable or otherwise to his employer and indicates whether he belongs with the common run of untrained and inexperienced men or is entitled to his professional status as an engineer. The dollars and cents side of an engineer's duties may not be the most pleasant feature of his employment, but the working out of the business problems of his projects is an important part of the reason for his employment and will well repay close study and attention.

Letters to the Editor

PRESSURES IN PENSTOCKS CAUSED BY THE GRADUAL CLOSING OF TURBINE GATES

Sir,—I am very much pleased to find that you thought my discussion on water-hammer of sufficient interest to publish it in full in your esteemed paper, issue of September 25th. May I ask you to record the following correction in your next issue, in order to avoid possible misunderstandings:—

Seventh line from top, first column, page 329, "to the area of the gate opening at the time, $t = 0$" should be changed to "to the (assumed) constant area of the penstock, i.e.,

$\psi(t) = (1-t/T)[c_o/(2gy_o)^{1/2}]$."

This mistake was discovered too late to be corrected in the original of my discussion.

EUGENE HALMOS

New York City, November 8th, 1919.

ENGINEERING OPPORTUNITIES IN CHINA

Sir,—"For ways that are dark and tricks that are vain, the heathen Chinee is peculiar." When Bret Harte thus summarized his conception of Chinese character, his estimate and ultimatum were accepted by some millions of "whites" as a final proposition. It ends in a cul-de-sac so far as the average man is concerned, and he is content to mentally add "finis" to things Chinese and direct his attention to other matters and other peoples.

In this attitude he is probably justified if his time is limited or his sphere of activities confined to American or Western European fields. The engineer, however, is not, or should not be, included among those who dismiss the Asiatic with a well-turned phrase and a shrug of indifference. He can learn many things to his advantage from the "yellow race" if he is so inclined and will forget (for the time at least) that he is a superior being, and that he has some centuries of human progress and development behind him which the other has not.

It is generally conceded that China, of the individual "promising fields," offers the largest and broadest scope for development, both commercially and industrially. If this be conceded, it naturally follows that the commercial and industrial activites must be supplemented and, in some cases preceded, by engineering activities involving exploration, study, experience and works. The field is undoubtedly there. The need for the engineer who can visualize and initiate development works is great, but it is imperative that the engineer who intends to share in the development, approach his task with the proper perspective.

Blueprints Are Useless There

China is not virgin territory in the sense that was, or is, Canada, the western states, the African colonies and the South American republics. It is older than the pyramids in race, customs, habits and pursuits. The traditional conservatism of the Englishman is vacillating radicalism when compared to that exhibited by the Chinaman in authority until it is indisputably proven to the Chinaman that it is to his advantage to throw over the old for the new.

Do not try to sell an article or a project to a Chinaman from a blueprint! Show him a photograph; or better still, demonstrate on a small scale, and, if you have adapted your proposition to what he requires or would like, and not to what you think he should have, you have a shrewd but open-minded prospect. Here is a wonderfully inviting field for the young engineer of some experience and undoubted ability who finds his progress blocked or his field overcrowded at home by older men already established.

The mercantile and contracting-engineer concerns of Canada who are looking afield for new business and customers, are awakening to the possibilities in the Far East, but they seem to be overlooking one important element to success. They must have technically-trained men on the ground, as a very few American and British firms have. It is not sufficient to sell a Chinaman or the Chinese government a dredge (for example), send a man over to set it up for operation, and consider the transaction closed. In case of a breakdown or a necessary adjustment for different raw material, an engineer should be easily and quickly available to render the necessary service and advice.

Big Plant Stands Idle

A Chinese company manufacturing hosiery and other knitted wear, was prevailed upon to install two American knitting machines of excellent design and output capacity. A qualified mechanic installed them and remained long enough to see that they were operating. Two weeks after his departure the machines stopped. They were still lying idle two years later when one of the owners, happening to meet a mechanical engineer in Hong Kong, took him home to see the factory. Noticing the discarded machines, the engineer asked permission to set them up again. Three days later they were running to capacity and have continued to do so.

A progressive Chinaman decided to substitute steam for man and animal power in his plant. An over-zealous salesman sold him a boiler and engine generating and delivering five times the amount of power the plant required. It was always too costly, but the war came and coal rose in price and was difficult to get in sufficient quantity. The plant is again run by the original power. The solution of this man's problem lies, not in specifying a smaller power plant, but in utilizing a waterfall quite close to the property to generate both light and power. It is probably not yet too late, but Mr. Canton has a mortal fear of being bitten twice in the same place.

Typical cases could be multiplied, but the sight of a $500,000 dredging plant lying idle in one of the fairly important harbors on the coastline, while some two or three hundred primitive, native dredgers are carrying out a fine piece of harbor deepening and reclamation work nearby, is sufficient demonstration of the fact that governments, as well as individuals, have suffered from a lack of advice from technically trained and experienced engineers.

Pioneer and educational work in developing a market for exports and for securing contracts involves considerable expense at best, but the manufacturer or contractor who supplements his sales efforts by an investment in technical service is building up capital in prestige and good-will. Cognizance is taken of this latter fact at home; why lose sight of it when entering a new field?

Group Export Associations Needed

An adaptation of the "grouping" or "circular" export associations being formed by various American firms, is worthy of serious consideration by members of the Canadian Manufacturers' Association and similar bodies. These groups are composed of a varying number of non-competing houses which combine to form a subsidiary export or trading company. An office is opened in Shanghai or some other of the treaty ports or commercial centres, and the expense is shared by the members according to agreement.

This scheme would seem to be meeting with a satisfactory amount of success, but too much effort has been given to the sales end and too little to the educational, constructional and technical features of the campaigns. Each of these groups should, advisedly, have in its employ a general contractor member, and at least one technically-trained engineer, resident at the foreign office and possessed of initiating ability that will not allow of his becoming a mere travelling mechanic or instrument man.

The number of modern manufacturing plants in existence in China is ridiculously small when the consumer market and the raw materials available are taken into consideration. The number of wealthy Chinamen who are good prospective large-scale manufacturers is much greater than

.s generally supposed on this side of the Pacific. An attractive field for development is suggested by these conditions and admit of almost unlimited expansion if attacked in an aggressive and comprehensive manner.

This view, that the Chinaman should be encouraged to manufacture his own raw materials into consumable products, may be a new one, and it probably will not meet with favor on the part of our importers of these raw materials. It is, however, self-evident that if we supply machinery, building materials and equipment for fabricating the finished products, we benefit in the first instance and the Chinese workman earns money to buy more of our distinctively Canadian exportable commodities. The introductory work suggested is not as difficult as it appears in prospect.

Win Feng, compradore for a Canadian trading company, is in a friendly and intimate business standing with a number of prominent Chinese merchants; among these is Sin Foo, an exporter of hides and skins. It is suggested that it would be more profitable for Mr. Foo to erect a tannery and export leather. The trading company stands ready to supply technical service, plans for the building and plant and, if necessary, will arrange for the supply of a skilled foreman. Mr. Foo, and possibly some of his friends, decide to become manufacturers. Contracts and orders for machinery follow.

The engineer who is included in any organization in the Orient will find that he is continually picking up valuable suggestions in the native processes which will assist his principals in designing buildings and machines peculiarly adapted to local conditions and requirements. In this connection it is suggested that a civil and a mechanical or electrical engineer should be attached to each of the Dominion Trade Commissioners' offices in the Far East.

P. E. DONCASTER,
Public Works Department.
New Westminster, B.C., October 18th, 1919.

MINERAL RESOURCES OF CANADA, WITH SPECIAL REFERENCE TO LIGNITES AND THEIR TREATMENT

Sir,—It is no secret to the well-informed, the observer the reader and the traveller that there are enormous mineral deposits in Canada. These deposits are of the richest kind, and of almost every description. It only requires inventiveness, specialized application and practical knowledge and experience, combined with moderate capital, to produce from these raw materials an abundance of the most essential and now greatly needed commodities to replace the depleted stocks destroyed in the great struggle and to meet the increased demands of the future.

The world is gradually approaching an oil age, an age rapidly approaching, due to the progress made in the development of the internal combustion engine. Ships of every description will be adopting this method of propulsion before many years are passed; the heavy oil engine of the Diesel type will be in common use for marine work. The submersible ship of the future will largely depend upon oil for driving; the motor car, the aeroplane and a thousand other applications of the internal combustion engine are becoming more common daily. Oil will vie with "white coal," of which Canada has such an abundance. The demand for fuel spirit, fuel oil and motor spirit is increasing rapidly, and it will go on increasing.

For years to come the world must practise the strictest economy; everything must yield to the utmost. The great wastes of the past must be abolished, and it is only by conservation and economical utilization of the natural resources that we can recover our stability. Canada is in the finest position to perform a great part in this reconstruction. Its resources are such that it could provide for the needs of a great percentage of the human race. Its mineral wealth is as yet barely glimpsed. One has only to leave the beaten trail for a few miles to see the vast riches of the earth cropping out in every direction. Coal, lignite, oil-bearing shales and oil-bearing sand are the commonest but not the least valuable of our mineral deposits.

Observe the east and the west of the country, where there are limitless measures of the finest bituminous coal, only waiting human genius to wrest vast quantities of oil, spirit, chemicals and fertilizer from these stores of raw material. At present much of man's labor is wasted, especially in the coal fields of the west, where no care is taken to conserve the by-products which represent the most valuable portion of the coal mined. These valuable products are "going up in smoke." Beehive ovens are employed to produce coke for the smelters, ignoring other products.

Consider what underlies the prairie provinces: Billions of tons of the finest lignite. The people of that region need not import fuel if the material which lies beneath their feet is properly treated, and as it can be commercially treated. They need not want for cheap power to develop their industries. They need not regret that they have not the vast water powers of other provinces. Nature has provided for them by giving them these vast stores of buried sunshine, fuel, power, light, heat and many useful by-products besides, such as oil, spirit, gas, fertilizer and chemical bases. All that lignite requires is treatment.

Dormant Wealth East and West

Imagine the dormant wealth lying under the surface of the ground in the maritime provinces—billions of tons of rich oil-bearing shale which, under treatment, would yield per ton of shale an average of 50 gallons of crude oil, 60 lbs. of sulphate of ammonia, and other by-products.

Few people realize the great deposits of oil sand and bitumen lying hidden away in the northwest, but they exist, and only need exploiting. The object of generalizing is to remind the reader that we have these advantages, and that Canada must bestir itself and make development rapidly. Unfortunately the reticence which permeates all governments, is preventing progress. Good men are employed but are bound round with red tape. Capital is offered for development, but is rejected on the grounds that private enterprise and development might result in unhealthy monopoly of common property. Whether the enterprise is private or governmental, it must be made, and made soon. Private development is better than governmental, and it can be controlled by sound legislation. Progress and development of a country means progress and betterment of the people of that country. Let us progress!

The great war has brought out latent powers, sharpened wits, and forced development in many directions. It has brought forward more economical methods and processes for the treatment of raw materials. This is very noticeable in processes dealing with fuels, oils and by-products. J. A. Yeadon, of England, a mining engineer, has for many years been working on a system to carbonize coal and to obtain the by-products from it cheaply and to improve the quality and quantity of same. He has for a number of years experimented with automatic retorts to carbonize coal, oil shale, lignite and other analogous materials at low temperatures. With the assistance of other experts, and chemical engineers, he perfected his system, or process, in the early days of the war.

For years attempts have been made to solve this problem, but with indifferent success, but up to the time of Mr. Yeadon's perfecting his process, no one had been able to make the low temperature carbonization process a commercial success. The retort designed by Mr. Yeadon has solved the difficulty.

Retort for Carbonizing Lignites

This revolving horizontal retort is of special design and construction, with a view to dividing up the charge into fine streams and thus effecting perfect carbonization at a uniform rate, at the same time automatically working the charge through the retort in a continous stream. The speed of carbonization is under perfect control, so that the material need only make one passage through the retort from the point where raw material enters to the point where the carbonized material is extracted. During the progress of the material through the retort, the by-products are extracted in gaseous form. This gas passes up to the hydraulic main, the hydro-carbons are extracted, and from thence it can be used for various purposes. The residuum or car-

bonized material, if coal or lignite, can be turned into fuel for domestic purposes, steam raising, power gas plants, or smelting of ores in blast furnaces, depending on the preparation, which is varied to suit requirements.

The process of coal carbonization can be divided into two distinct systems:—

(a) High temperature carbonization, the chief function of which is to extract the maximum amount of gas for illumination purposes, heating, cooking, etc.

(b) Low temperature carbonization, which is specially adapted to the production of the maximum of by-products, comprising crude oil, sulphate of ammonia, chemical bases and carbon residue.

In speaking of coal, it is meant that shale, cannel, lignite and other analogous materials are included, such as can be treated in a heated retort or other closed vessel for the purpose of producing gas and by-products.

New Low Temperature System

In the high temperature system, notwithstanding the high heat applied, the coal must remain in the retort for a long period—6 to 8 hours—before it is considered to be sufficiently carbonized. Thus it naturally follows that the lower the heat of the retort the longer will be the time required for carbonization, and the smaller the quantity carbonized in a given time in a retort of given dimensions.

These difficulties are further increased in proportion as the smaller sizes of coal are fed into the retort, as these lie "dead." In low temperature carbonization various schemes have been adopted to assist this slow process of carbonization, such as internal shafts, travelling chains, stirrer arms, and other appliances to work inside the retort for the purpose of agitating and stirring up the charge and conveying it through the retort, with a view to getting a more rapid and thorough carbonization. So far these efforts have met with but very indifferent success and have proved of no commercial value.

The invention described in this letter was designed to meet and remedy the aforementioned defects by combining the principle of low temperature carbonization with two other important processes, neither of which had hitherto been worked in conjunction with same.

In the first process the coal is pulverized to a granulated condition, thus allowing the use of the smallest and consequently the cheapest grade, also allowing every particle of coal to come into quick contact with the surface or reflected heat inside the retort, and by this means securing rapid and almost instantaneous carbonization, This necessarily finely granulated condition of the charge is further ensured by drying and partially heating the coal before entering the retort.

In the second process this rapid carbonization is secured by the use of a tapered revolving retort into which the coal is continuously fed at the one end and the carbonized material continuously discharged at the other, both operations done mechanically and automatically."

Automatic Feed and Discharge

The retort is corrugated longitudinally, the corrugations serving a dual purpose: (a) To strengthen the retort body; (b) to increase the internal heating surface; and (c) to agitate the layer of finely granulated coal in its passage through the retort. There are no moving parts inside the retort to give trouble. The charge is fed into the retort by a self-sealed revolving screw feed and is discharged by a similar appliance at the opposite end. The feed and discharge are continuous and automatically controlled without any ingress of air or egress of gas.

The discharged carbon is in an ideal state for being agglomerated with a small proportion of bituminous matter or lime, and converted into block fuel, especially valuable for domestic purposes or for manufacturing uses. The fuel is practically smokeless.

The retort can be heated by part of the gas produced in it.

Labor is reduced to a minimum, and no skilled attention is necessary to operate the retort bench. The capacity of the retort is very great and much exceeds any other form of carbonizer, gas works retort or coke oven. The product is more uniform in quality, whether gas, oil or carbon is the objective.

A great feature in favor of this type of retort over the coke oven is the ease with which the plant can be increased without disturbing the existing plant, its great capacity for producing a large amount of the highest quality of blast furnace fuel at a low cost, and the continuous process of manufacture.

As a smelting fuel, the carbon is superior to coke. The granulated carbon is turned into blocks of 20 lbs. weight very cheaply, and in this form it is strong and capable of carrying a very heavy "burden." It takes up a position in the furnace which tends to produce perfect combustion, admitting of the blasts having a free course, and thus producing a more uniform heat throughout the furnace, and reducing the amount of fuel per ton of ore smelted.

This fuel is almost pure carbon; it has no equal for open fires or closed furnaces. It is practically smokeless, whether made from bituminous coal or lignite, and the calorific value is greater, weight for weight, than the raw material.

In the manufacture of smelting fuel, the agglomerate may be hydrated lime, whilst in the manufacture of domestic fuel, very little agglomerate is required if the retort works in direct conjunction with the press. If agglomerant has to be used, it may be the pitch produced from the carbonization, or tar, sulphite pitch or the residuum from oil refineries, or a mixture of the two latter. It depends entirely on local conditions and circumstances.

Says Private Capital Is Available

The carbon makes an excellent fuel for producer gas plants, and in this connection a good yield of sulphate of ammonia is obtained. The volume of good, clean gas of first-class quality is very great. The retort can be adapted to producing gas for domestic use and its adoption places within the reach of every small town a public supply of gas for heating and lighting purposes.

Canada has the raw material; it wants only brains and money to exploit them. There is no dearth of brains, experience and practical knowledge, and the capital is forthcoming providing that the owners have the co-operation and protection of the government. In other words, let the provincial governments grant concessions for the development of these resources by private capital and by men who know how to do it; it is not amateurs' work. Resources, men and money are available and waiting to develop Canada.

WILLIAM ARMSTRONG.

Montreal, November 4th, 1919.

The Ontario Section of the American Society of Mechanical Engineers held its first meeting of this season last Friday evening. The season's work was discussed, and it was decided to hold one meeting per month, the meetings to be alternately a technical session and a dinner with an address. Members of the society came from as far as Chatham, London and Belleville to attend last Friday's dinner, and it was felt that this indicated that considerable interest would be taken in the work this season. After the dinner, which was held at the Engineers' Club, Toronto, Brig.-Gen. C. H. Mitchell delivered an address upon some phases of mechanical engineering which had come under his observation in France and Italy during the war. He particularly covered transportation and the mobile shops in the advanced areas in France. He made some interesting observations regarding Italian hydro-electric power developments as he found them at the end of the war in comparison with their condition and size in 1906. He also gave a vivid description of the Italian engineering feats in the construction of the "teleferrica," or wire cableways, which transported munitions and men in hanging carriers over mountainous peaks and across great chasms even when subject to heavy shell fire.

PROBLEMS AFFECTING DESIGN AND CONSTRUCTION OF HIGHWAYS*

By W. G. Thompson
State Highway Engineer of New Jersey

IT has been said by a well-known railroad executive that the railroad of the future may find it more economical to tear up short-line tracks and develop motor truck transportation in their place. Although the supplying of tonnage is the freight traffic manager's problem, it is also a problem which should engage the serious attention of the engineering department, from the viewpoint that every means should be employed to reduce the cost of supplying tonnage to the main lines, just as careful attention is given in location and construction, to reducing grades and curvature to the minimum. It is claimed that, considered as a unit, few branch lines pay expenses, but as gatherers of freight and passengers to increase density of main-line traffic, they are sources of profit. As, however, traffic gathered by them is turned over to the main lines with a deficit attached, which has to be overcome during the main-line movement before any profit is made, it might be a decided advantage if this traffic could be delivered to the trunk line by means of the motor truck or tractor, without this bill of expense attached.

May Eliminate One Handling

Since it is a fact that it is now necessary to truck products of all kinds, and especially farm products, to the short branch line, and load them into cars, a serious investigation of the matter may disclose that one handling might be obviated and considerable expense saved if the tracks were removed from many branch lines and the grade used for an improved motor road, which could be entered from every intersecting highway. Such an arrangement would mean increased facilities at main-line points for freight handling, but with the present rapid improvement of country and interurban highways, it would relieve the railroads of the burden of maintaining freight stations, water systems, coaling stations, track and other structures, and the inevitable overhead expense during seasons when traffic is light.

It is inconceivable that trunk highways paralleling trunk lines of railroads will ever seriously affect the tonnage carried by the railroads, but it is quite conceivable that with the extensive building of hard, smooth, all-year highways, the tonnage of branch line roads will be very seriously affected, and in my opinion this problem should from now on engage the attention and induce careful investigation by the engineering departments of railroads, whose managers are looking to the future and the economical handling and transportation of freight.

There are, at present, approximately 6,000,000 passenger motor cars in the United States. Conservative estimates place the passenger mileage of automobiles in the United States at 45,000,000,000 per annum. Commercial motor cars increased from 60,000 in 1912 to approximately 600,000 in 1918. The mileage for all kinds of commercial motor cars is now estimated at 5,000,000,000 ton-miles per year. It is estimated there will be in use at the end of the next 10 years 20,000,000 passenger and 5,000,000 commercial motor cars. Surely the above figures should cause railroad officials more than casual concern and lead to consideration of the matter of short-line hauls from the highway viewpoint.

Same Principles of Design

Highway engineering to-day differs little from railway engineering. The same fundamental principles are involved in the original design of both—viz.: Alignment, grades, curves, drainage of subgrade, bridges, superelevation of curves, etc. There must also be traffic regulations and signals, danger signs, distance and direction markers, etc. Particular attention is being given to grades and curves, especially on the New Jersey state highway system, where, except in very hilly country, 5 per cent. grades and 6 deg. curves are the maximum.

*From an address before the New York Chapter of the American Association of Engineers.

The advent of the swiftly moving motor vehicle soon demonstrated that the earth and macadam pavements were unsuitable and uneconomical for that class of traffic, therefore the most durable types such as concrete, stone block, asphalt and brick pavements are now being laid. Light foundations and inadequate drainage are the most fruitful causes of pavement failure, as they are in track construction. Systems should be provided for thorough drainage of the sub-foundation, such as lateral drains under the pavement, leading to longitudinal drains; the construction of storm sewers on a grade in long, level sections; and the construction of side ditches and gutters. In the preparation of sub-foundation, all areas of permanent saturation are removed and replaced with coarse sand or broken stone placed directly beneath the pavement. Experience is developing the fact that concrete provides the most durable and lasting foundation under heavy traffic. It is being used in rapidly increasing amount as a pavement and as a foundation for other types of pavement.

Widths, Thicknesses, Curves, etc.

On country and interurban highways, graded widths from gutter to gutter are not less than 30 ft. and the hard pavement not less than 18 ft., widening to 24 to 30 ft. where several roads converge, or when approaching large cities. All curves exceeding 3 degs. are superelevated, as in railroad practice, in accordance with a formula devised for the purpose and based on a speed of 30 miles per hour, though some of our banked curves have been driven at 60 miles per hour, presumably because the driver liked the sensation of rounding a curve at high speed without the effort of resisting the overturning force.

Laws of most eastern states permit gross loads of from 24,000 to 30,000 lbs. on trucks, therefore bridges are being designed for 20-ton loads, assuming 75% of the load as being on the rear axle.

Rapid increase in use of motor vehicles makes pertinent the question as to whether we are building pavements sufficiently wide and foundations sufficiently heavy. The first is a matter of local finances; the second is one which can be determined only by experience and observation, extended over a period of years. On our most heavily traveled route, that between Newark and Trenton, we are laying a concrete pavement 8 ins. thick at the sides and 10½ ins. at the centre. On all other routes the pavement is being laid 6 ins. at the sides and 8¾ ins. at the centre. It is believed these will suffice for 15 or 20 years.

Public Service Conditions Changing

A comprehensive system of marking the highways with danger, distance and direction markers is being installed to enable the motorist to travel from place to place with convenience and safety, if he will but observe the traffic regulations and ordinary courtesy to others.

Highway and highway transportation engineering offer a broad, promising field to young engineers in the future. There are objections to employment in public service, the principal one being uncertain tenure of office, due to changing political administrations, but it is within the power of the engineers of this continent, by united and persistent effort, by educational propaganda, the exercise of tact, good judgment and constant adherence to the high ideals which actuate 99% of our engineers, to so mould public opinion that within a very few years the civil engineer may attain the social and economic status which is rightfully his, especially in the administration of public business and affairs. To most engineers, the idea of mixing or entering into politics is repugnant, but the present political system and the appointment and election of misfits and unfits will continue until the people of this great nation are educated to demand trained, experienced, practical men for the conduct of public affairs.

METHODS OF PUMPING IN ONTARIO

ACCORDING to a private report recently made by an engineer who had investigated the water works and fire protection systems of practically all the municipalities of Ontario, three-quarters of the municipalities depend for their water pressure upon steam only, electric power only, gravity only or a combination of steam and electric power. No less than 43 municipalities out of a total of 171 (or 25%) last year had facilities for pumping by steam only; while 39 (or 22.8%) had both steam and electric pumping; and 27 (or 15.8%) pumped by electric power only; 18 municipalities (or 10.5%) having gravity systems. The following table indicates comparatively little change in the situation since 1916:—

NUMBER OF MUNICIPALITIES IN ONTARIO, IN YEARS 1916-8, HAVING WATER SUPPLY AND FIRE PROTECTION SYSTEMS, AND KIND OF POWER UPON WHICH THE PRESSURE DEPENDED

	1918	1917	1916
Steam only	43	46	50
Water power only	6	7	8
Electric only	27	23	24

STRAIT OF BELLE ISLE DAM

REFERENCE was made in a recent issue of *The Canadian Engineer* to a daily newspaper dispatch stating that "the climate of Newfoundland would be changed if a breakwater were built across the strait of Belle Isle, between the island and the mainland, and the cold Labrador current shunted out into the Atlantic Ocean.

"Such a dam is being seriously considered," continued the newspaper article. "It would cost an immense sum of money, but engineers say it presents few difficulties. The Labrador current, at present, is the chief factor in moulding the climate, not only of Newfoundland, but of the Maritime Provinces and New England. Coming down from the Arctic Ocean, it pours through the strait of Belle Isle, and, circulating around the gulf of St. Lawrence, washes with its cold flood the coasts of Newfoundland, Quebec, New Brunswick and Nova Scotia."

James White, deputy head of the Commission of Conservation, Ottawa, calls our attention to the fact that the strait of Belle Isle, at its narrowest point, is 11 miles wide, and that it has a maximum depth of 330 feet and an average depth of 215 feet.

Ignoring such "details," moreover, there is the further drawback that the Labrador current does not "pour through the strait" and does not wash with its cold flood the coasts of our Maritime Provinces. Several years ago Dr. W. Bell Dawson, superintendent of Tidal and Current Surveys, ascertained beyond doubt that such current as there is, ebbs and flows with the tide, and does not set through the strait, either from the east or from the west.

PULVERIZED FUEL

THE Commission of Conservation has just issued a report on "Pulverized Fuel: Its Use and Possibilities," by W. J. Dick, which may be had on request by those interested in economy of fuel for power and large heating plants.

One of the pressing problems of industry in Canada is that of fuel supply. This is especially the case in manufacturing processes requiring heat. The rising costs of coal and the difficulty of transportation have proved handicaps of considerable importance, and are rapidly becoming accentuated. This situation demands that all the available heat contained in the coal be made use of. In the utilization of run-of-mine coal, a large proportion is lost in the form of cinders and clinkers. To overcome this waste, a process for using coal in pulverized form is now in successful use.

Under this process the coal is first dried to reduce the moisture content to approximately 1%. It must then be ground until 95% will pass through a 100-mesh screen and 85% through a 200-mesh screen. The coal is then transferred, usually by screw conveyors, to the furnace supply, whence it is blown into the fire-box by means of compressed air. Consumed in this way, the coal burns like a gas and the flame has the characteristics and appearance of a gas flame. Results of tests have shown that there is no formation of slag in the furnace or on the tubes, there is no shower of cinders or ashes emitted from the smokestack, and there is no damage done the boilers from heavy overload conditions.

Canada is particularly interested in the use of pulverized coal. At the pit-head and underground at the mines in Nova Scotia and British Columbia are great piles of unmarketable coal dust and slack, while in Alberta and Saskatchewan there are immense reserves of lignite which is high in moisture content. This lignite rapidly disintegrates on evaporation of the moisture, and, consequently, will not stand transportation. It is also unsuitable for locomotive fuel on account of its liability to start fires from excessive sparking. But these coals, by drying and pulverizing, make excellent fuels for either heating or power-development purposes. They are lower in price, less expensive to handle and give greater heating value. The Dominion Coal Co., at New Waterford, N.S.; the International Nickel Co., at Copper Cliff, Ont.; the

British Columbia Sugar Refining Co., at Vancouver; and, with one exception, all the cement companies in Canada, are using pulverized coal with very satisfactory results.

PERSONALS

LEWIS W. WYNNE-ROBERTS, who has just returned to Canada after three years' military service in India and Mesopotamia, was born November 14th, 1891, in Carnarvon, Wales. His father is R. O. Wynne-Roberts, consulting engineer, Toronto, who went to South Africa in 1898 as city engineer of Capetown. Consequently L. W. Wynne-Roberts received his primary education at the South African College School in Capetown, subsequently studying engineering at the Day Technical College, University of London, Eng., where he was a gold medallist and graduated with honors in 1912. Shortly after his graduation he followed his father to Canada and joined the staff of the Provincial Board of Highway Commissioners at Regina, Sask., as assistant engineer on design of concrete bridges.

Among other work, he assisted in the design of the Saskatoon bridge, one of the largest and most notable of its kind in Canada. In October, 1915, he resigned from the staff of the Highway Board in order to go to England for the purpose of enlisting in the army. He obtained a commission as lieutenant in the Royal Engineers; and in the fall of 1916 was sent to India, where he was loaned to the Indian government and became engineering instructor to British officers who were connected with the 2nd Sappers and Miners of Bangalore. After six months of this work, he requested a more active post and was sent to Mesopotamia with reinforcements for a field company of engineers. In Mesopotamia Mr. Wynne-Roberts was engaged under Generals Maude and Marshall in general field engineering work, including water supply, bridges, demolition work, etc. In July, 1918, he was promoted to the rank of captain and was sent to Northern Persia as one of a party of five engineers who were entrusted with the contruction of a water-bound macadam road from Ruz to Hamadan, a distance of 370 miles This road formed a part of the Bagdad to Baku route and was necessary for the transportation of supplies to the British force operating in the vicinity of the Caspian Sea. The five engineers divided the work and each had less than 10 weeks in which to make passable over 50 miles of highway solely with the aid of native labor and without any machinery or tools excepting those made for them in the Persian bazaars. The entire route had been impassable the previous spring, and there were also a large number of antediluvian bridges that needed repair in order to carry the army's motor trucks. The stone for the repair of the road was broken with sledges by women and children and carried to the job in bags on the backs of donkeys, in some cases for a distance of 6 miles. These animals also transported the water in old kerosene oil cans. Mr. Wynne-Roberts left Persia in April of this year but upon his arrival in India was sent to the Afghanistan frontier for several months and was unable to sail to England until August. He was released from military duties upon his arrival in England and landed in Halifax two weeks ago.

L. D. WALKER, of Ottawa, has received an appointment on the Welland Ship Canal engineering staff.

W. S. ATWOOD and A. D. NEALE have been appointed vice-presidents of the Canadian Car and Foundry Co., Ltd., Montreal.

H. H. VAUGHAN, general manager of the Dominion Bridge Co., Ltd., Montreal, has resigned in order to devote his attention to other interests.

W. F. MCKNIGHT, sales manager of the wire and cable department, Northern Electric Co., Ltd., Toronto, has been transferred to the head office at Montreal and has been appointed educational director for the company.

S. L. SQUIRE, of Toronto, and GEO. A. MCNAMEE, of Montreal, who are respectively president and secretary of the Canadian Good Roads Association, expect to visit Winnipeg at an early date in order to arrange the details of the annual convention which will be held in that city next May.

C. A. MAGRATH, of Ottawa, chairman of the Canadian section of the International Joint Commission, has been reappointed to the office of Dominion Fuel Controller in view of the serious situation that has arisen in regard to the importation of bituminous coal from the United States, due to labor troubles in that country.

OBITUARY

JOSEPH A. DOWNEY, contractor, Toronto, died last Saturday, at the age of 45. The late Mr. Downey was born in Dixie, Ont., but entered contracting work in Toronto when he was 20 years of age.

TOWN PLANNING CONFERENCE AT HAMILTON

THE preliminary program for the third annual Town Planning Conference of South-Western Ontario, which is to be held next Thursday and Friday in Hamilton, Ontario, includes suggestions for discussion on the following proposed legislation: Power to adopt a town planning scheme with suitable regulations for housing, sanitation, height of buildings, width of streets, etc., and for establishing zones for industrial, commercial and residential purposes; the formation of town planning commissions on which city councils are to be represented, these commissions to have their powers limited by having to submit to the city councils any schemes involving large expenditures; power to provide for gradual and economical street widening in congested areas by fixing a building line; reasonable limitation of damages claimed on account of town planning schemes, and permission for town planning commissions to share in increased values caused by the carrying out of their schemes; permission to buy, own and sell land other than that actually required by town planning commissions, such purchase to be for the purpose of profiting by the increased values caused by the carrying out of the schemes, thus assisting in paying for same; power to co-operate with suburban areas in developing along lines consistent with mutual interests. Other discussions will be on housing problems in the United States and Canada, municipal government and reconstruction, legislation and town planning, beauty and health in relation to town planning, town planning in relation to industrial development, zoning, and the question of whether town planning is profitable. The speakers at the conference will include Lawrence Veiller, Dr. Horace L. Brittain, S. Baker, J. A. Ellis, Sir John Willison, Thomas Adams, Noulan Cauchon, Mrs. Dr. S. Lyle, C. A. Kirkpatrick, and W. J. Donald.

J. C. Davies, managing director, and Roger Beck, director, of Baldwin's, Ltd., Swansea, Wales, are in Toronto to supervise the initial operations of Baldwin's Canadian Steel Corporation, Ltd.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

ADDITIONAL TENDERS PENDING

Not Including Those Reported in This Issue

BRIDGES, ROADS AND STREETS

Brandon, Man.—Brandon will probably link up with Crystal City in a good roads scheme, the city council having received a letter from F. H. Barnard, secretary of the Sunshine Highway, recommending this action being taken. The matter has been referred to the Good Roads Committee of the city council.

Carstairs, Alta.—Town council plans construction of concrete walks. Cement mixer may be purchased. Secretary-treasurer, L. Aldrich.

Chippawa, Ont.—Tenders, addressed to Sir Adam Beck, Chairman, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, will be received until 12 o'clock noon, November 28th, 1919, for the construction of the Chippawa Highway Bridge. Plans and specifications may be obtained from the chief engineer.

Hull, Que.—City council plans erection of bridge. Engineer, J. P. A. Laforest.

Kingston, Ont.—City council passed a by-law for the construction next spring of a bituminous pavement on a new macadam base on Nelson St., from Princess to Johnson. City engineer, R. J. McClelland.

Millardville, B.C.—Repairs to the Clarke Rd., which connects Port Moody and New Westminster, will be commenced in the near future. Repairs will also be made to the Brunette River bridge.

Niagara Falls, Ont.—The C.P.R. has surveyed a line from the north of Welland city, touching the boulevard about one and a half miles above Black Creek, where an international bridge will be built, crossing the river to Buffalo. It is supposed that the bridge will be built to carry electric cars and other vehicular traffic. According to the estimates, the bridge will be the last word in engineering.

Quebec, Que.—The private secretary to the Minister of Roads states that while Quebec's highway work will be continued along the same construction lines as in the past, there is no definite plan at present of spending many millions of dollars as recently reported or of building as much as 6,000 miles of roads next season.

Simcoe, Ont.—Plans for construction of five bridges are being prepared by G. R. Marston, engineer.

St. Athanase de Bleury, Que.—Tenders will shortly be called for construction of gravel road. Engineer, M. Henry, Roads Department, Parliament Buildings, Quebec

Ste. Cecil de Whitton, Que.—Tenders will shortly be called for gravelling road at cost of $85,000 for municipality of North Whitton. Engineer, M. Henry, Roads Department, Parliament Buildings, Quebec.

St. John, N.B.—Plans and specifications will be prepared for the paving of Douglas Ave., City Road, Brussels St., and Marsh Road, the work to be done by contract. City engineer, G. N. Hatfield.

St. Pamphile, Que.—Tenders will shortly be called by municipal council for construction of steel bridge. Engineer, Ivan Vallee, Public Works Department, Parliament Buildings, Quebec.

Three Rivers, Que.—Plans prepared for railroad bridge for C.P.R., Montreal. Cost, $50,000. Engineer, W. B. Harper.

Toronto, Ont.—Board of Control let contract to the London Concrete Machinery Co., Ltd., London, Ont., for one No. 4 special concrete mixer with 3 h.p. Novo gasoline engine.

Toronto, Ont.—Works committee recommended adoption of Works Commissioner's report for the grading of Stacy St., Coxwell Ave. to Drayton Ave. Estimated cost, $4,685. Also grading of Hillingdon Ave., Hanson St. to Danforth Ave., cost, $4,920.

Toronto, Ont.—The plan to extend University Ave. through from Queen St. to Front St. was adversely reported on by Finance Commissioner Bradshaw, Works Commissioner R. C. Harris and Assessment Commissioner Forman at a recent meeting of the Board of Control. The officials estimated that the project would be too costly. They favored an alternative plan for a new street midway between York and Bay Sts., from Queen to Front. The work, however, will not be undertaken at present owing to the general financial situation. However, the Board of Trade will hold a conference with regard to University Ave. extension plan.

Toronto, Ont.—Board of Control let contract for the construction of concrete curbing on Bristol Ave., to the Con-

TENDERS WANTED

Sealed tenders will be received by the undersigned, addressed to Chas. G. Booker Esq., Mayor, Chairman, Board of Control, City Hall, Hamilton, up to 5 o'clock p.m., on Monday, December 1st, 1919, for the manufacture of 1,994 lineal feet of 33-inch diameter Reinforced Concrete Pipe.

Tenders must be on forms supplied and plainly marked on the outside as to contents.

Specifications and form of tender for the above can be obtained at the office of the City Engineer, where any other information may be secured.

The lowest or any tender not necessarily accepted.

S. H. KENT,
City Clerk.

Hamilton, November 19th, 1919. 380

structing and Paving Co., Ltd., Confederation Life Chambers, Toronto, at 78c. per lineal ft.

Toronto, Ont.—Board of Control awarded contracts to R. C. Harris, Commissioner of Works for the construction of the following asphalt pavements: Bristol Ave., price, $9,-908; Herman Ave., $3,379; Hiawatha Road, $13,926; Sackville St., $11,257. Also for granite block pavement on Eastern Ave., from St. Lawrence St. to Broadview Ave., $37,-440.

Toronto, Ont.—The Board of Control recommended that the construction of the undermentioned local improvement works, authorized to be carried out by day labor, be transferred from the Commissioner of Works to the contractors named at the estimates submitted by the Commissioner of Works, as follows: Bitulithic pavement on Exeter Ave., from Laughton Ave. to the east end, to the Warren Bituminous Paving Co., McKinnon Bldg., Toronto, price $5,871; concrete sidewalk on Erie Terrace, e.s., from Queen St. to Gerrard St., to the Ramsay Contracting Co., 39 Indian Rd., Toronto, at $2.23 per lineal foot., to the Godson Contracting Co., Manning Chambers, Toronto; asphalt pavements on Kenilworth Ave., from Queen St. to 200 ft. north, price $3,157; Alvin Ave., from Heath St. E., to Glen Elm Ave., $4,959; Don Crest Road, from Third St. to Ozark Crescent, $7,661; Weston Road, $3,481.

Toronto, Ont.—Works Committee recommended the adoption of the Commissioner of Works' report for the construction of an asphalt pavement on Gerrard St., from Main St. to east city limits, at a probable cost of $182,441; asphalt pavement on Swanwick Ave., Main St. to Pickering Ave., cost, $36,720; bitulithic pavement on Edna Ave., Indian Road to Indian Grove, cost, $7,520; asphalt pavement on Crown Park Road, cost, $6,609.

Victoria, B.C.—City Engineer F. M. Preston submitted a report to the city council, recommending the preparation of a by-law authorizing the construction of the Johnson St. bridge on the basis of a city-owned structure for vehicular, pedestrian and street car traffic, costing in the neighborhood of $420,000.

Winnipeg, Man.—Tenders will be called by the Dominion government for construction of roads and sidewalks for military hospital. Plans with H. E. Matthews, Lindsay Building.

Winnipeg, Man.—The works committee's recommendation that $46,417 worth of improvements be proceeded with was passed by the city council. The works include a 24-foot asphalt pavement on River Ave., from Main to Osborne Sts. at a cost of $43,237. City engineer, W. P. Brereton.

WATER, SEWAGE AND REFUSE

Assiniboia, Man.—Contract for laying water main let to Dominion Construction Co., Winnipeg, and for sewer to Fowler & Young. Total estimated cost, $21,000.

Brooke Tp., Ont.—Township council plans construction of drain. Clerk, W. J. Weed, Inwood, Ont.

Chatham Ont.—The E. A. James Co., Ltd., engineers, 36 Toronto St., Toronto, who were consulted by the city to solve Chatham's water problem, have recommended to the water commission that the city should undertake a new waterworks scheme with Lake Erie as the source of supply. The report estimates the cost of such a scheme at $600,000. The water would be pumped to Erie Ridge, and flow by gravity to the city nearly 13 miles. The engineers were instructed to investigate the River Thames, the Snye Carte, and the lake as feasible sources of supply. The engineers estimate the cost of the Snye scheme at $700,000, and the Thames, $300,000. W. H. Westman, chairman of the water commission also favored the Lake Erie scheme. The three propositions will be submitted to the electors to decide upon at the municipal elections in January.

Crowland Tp., Ont.—Tenders will be received up to December 18th by H. L. Pratt, township clerk, Welland, Ont., for the excavating and laying of water mains in the Welland South district. Plans and specifications may be seen at the clerk's office, police station, Welland.

Elma and Blanshard Tps., Ont.—Plans for the construction of drains for Blanshard and Elma townships are being prepared by John Rogers, engineer, Mitchell. Tenders will be called.

Hamilton, Ont.—Tenders, addressed to Chas. G. Booker, mayor, chairman, Board of Control, City Hall, will be received by S. H. Kent, city clerk, up to 5 o'clock p.m., on Monday, December 1st, 1919, for the manufacture of 1,994 lineal feet of 33-inch diameter reinforced concrete pipe. Specifications may be obtained at the office of the city engineer.

Kitchener, Ont.—Water Commissioners decided to lay a 4-inch main on Onward Ave.

Logan Tp., Ont.—Tenders will be received by L. G. Rock, clerk, R.R. No. 1, Bornholm, Ont., until November 24th, for the construction of the Nicholson drain. Plans at clerk's office.

Milverton, Ont.—The town council have employed the E. A. James Co., Ltd., consulting engineers, Toronto, to prepare plans and specifications for complete water works installation. The plans contemplate deep wells, stand pipe, mains, together with electric pumping plant.

Montreal, Que.—The sum of $8,000 has been voted by the Administrative Commission for repairing a broken sewer in St. James St, between Richmond and St. Martin. It is estimated that 425 feet of the sewer will require to be renewed.

North Bay, Ont.—Town council is considering the construction of a water main on Fourth Ave. Town engineer, H. J. McAuslan.

Plympton Tp., Ont.—Plans and estimates for construction of drain are being prepared. Clerk, Thos. Nisbet, Wyoming, Ont.

Raymond, Alta.—The Southern Irrigation district, consisting of the lands tributary to Raymond, Magrath and Stirling, will, within the course of a few weeks be created into an irrigation district. At a special meeting held recently, attended by representatives from all these towns, the matter of organization was discussed, Hon. A. J. MacLean, Minister of Public Works, has advised the organization of the district.

South Vancouver, B.C.—Five tenders were received for ditch construction in the Collingwood East district as follows: $28,700, $18,000, $18,650, $14,343 and $14,343. The lowest, that of A. J. McDonald, of Vancouver, was accepted. The contract includes a monolithic sewer, 32,060 ft., and a 12-in. pipe sewer on Kerr Rd.

St. Thomas, Ont.—Ald. Curtis, Chairman Board of Works, will prepare plans for tile drain and septic tank.

Toronto, Ont.—Works committee recommended adoption of Commissioner of Works' report for construction of sewers on McKinley Ave. at probable cost of $8,480, and on Blake St. at cost of $7,630.

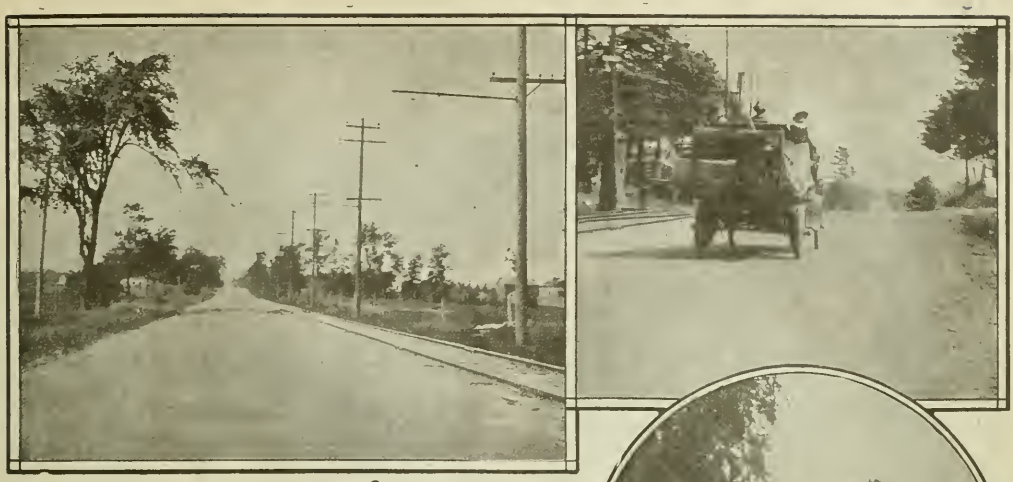
Toronto, Ont.—Board of Control let contract for an overflow storm sewer on College St. to John Maguire, Toronto. It is an $82,000 contract, and Mr. Maguire's tender was $140 higher than that of the lowest tenderer, W. C. Brennan, of Hamilton.

Toronto, Ont.—Board of Control let following contracts for construction of brick storm overflow sewers: College St., Beatrice St. to Palmerston Ave., to T. C. Agnew, 350 Concord Ave., Toronto, price, $35.50 per lineal foot; College St., Palmerston Ave. to Spadina Ave., to John Maguire, 265 Russell Hill Road, Toronto, $28.85 per lineal foot.

LIGHT, HEAT AND POWER

Hampton, N.B.—Town council plans installation of electric light plant. Cost, $18,000. Clerk, A. W. Hicks.

Lloydminster, Sask.—Contract let to Stewart & McPhee by town council for installation of electric light and power machinery.



Three views of Tarvia-filled macadam roads in County of York, Ont. Built with "Tarvia X" 1917, Toronto and York Roads Commission.

County of York (Ont.) Highways—Built and Maintained with Tarvia

THE highways shown in the three photographs are splendid examples of Tarvia roads.

All of these highways were constructed in 1917 with "Tarvia-X."

The photographs were taken more than a year later. Note the excellent condition of the roads—the smooth, firm, easy traction surface.

Tarvia Ideal for the Roads of the Dominion

Using Tarvia for a binder makes a road waterproof and frost-proof, and for that reason Tarvia construction is particularly suited to the requirements of the roads of the Dominion which must be able to come through the severe Canadian winters without damage.

Experience has proved that Tarvia does away with the extensive spring repairs that untreated roads nearly always need after a hard winter.

Indeed, Tarvia proves to be a good investment of the taxpayer's money, not an expense, for in the long run Tarvia *pays for itself in lower maintenance cost.*

For instance, an occasional Tarvia treatment will keep these County of York highways mudless and dustless, and in fine condition indefinitely at very small cost.

We shall be glad to give you further information about these County of York roads on request. *Booklets free.*

Tarvia

Preserves Roads-Prevents Dust

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by anyone interested.

If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention.

MONTREAL TORONTO WINNIPEG VANCOUVER

The Barrett Company LIMITED

ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Winnipeg, Man.—Officials of the Bruce Consolidated Mining Co. are investigating cost of construction of a power line into the Rice Lake district.

Winnipeg, Man.—Work on a new 110,000-volt transmission cable, to run from the Winnipeg power plant at Point du Bois, Man., parallel to the present cable, will be started immediately and completed before November, 1920, according to an announcement made by J. G. Glassco, manager of the city power and light department. The new line will cost the city $750,000. Extension to the city office, 54 King St., and to the power plant on the Winnipeg River will bring the total to be spent on improvements to $1,270,000.

RAILWAYS

Alberni, B.C.—The C.P.R. has let the contract to the Foundation Co. for the building of the extension of its railway line from Alberni to Great Central Lake, a distance of 10½ miles. It is expected it will be completed by next July.

Bulyea, Sask.—C.P.R. may construct a branch line to connect up Foam Lake with Bulyea.

Hamilton, Ont.—Ratepayers of Hamilton, on January 1st, are going to be asked to guarantee an additional $607,000 for the proposed Hydro-radial in this district. According to a statement made by Sir Adam Beck at the recent Hydro-radial meeting at Galt, Hamilton is one of seventeen municipalities which will be called upon to pass further by-laws. The extra $607,000 which Hamilton is to be asked to guarantee is for the work of tunneling under Hamilton cemetery and Harvey park, and connecting up the line from Kitchener, Guelph, Galt and Dundas with the main line to the border.

Ottawa, Ont.—The Department of Railways will in the near future link up the National Transcontinental Railway with the Canadian Northern, by the construction of a spur from Grant to Long Lake, about 200 miles east of Fort William.

Prince Albert, Sask.—Provided the Dominion government grants the needed appropriation, the C.N.R. will begin grading two branch lines in the Prince Albert district next spring. The first branch will extend for a distance of 45 miles in a northeasterly direction to Birch Bark Lake, and the other will extend a distance of 25 miles in a westerly direction from Shellbrook.

Quebec, Que.—Application will be made at the next session of the legislature for the incorporation of the Quebec and Chibougamau Railway, which intends to build a railway in this province. The names given among the applicants are Joseph C. Cote, agent, Quebec; William James Ewing, registrar, Richmond, Que.

St. John's, Nfld.—St. Georges Coal Fields, Ltd., plan extensive development work, and construction of new branch lines of railway. Manager, T. J. Freeman.

Toronto, Ont.—City council decided to submit to the ratepayers at the next civic election the agreement covering Toronto's participation in the construction of the proposed hydro-radial between this city and Bowmanville. The bond issue involved is for $4,328,665.

Whitby, Ont.—Whitby town and West Whitby township passed the by-law to guarantee the bonds of the proposed Toronto and Eastern radial.

FACTORIES AND LARGE BUILDINGS

Belleville, Ont.—Contract let to Thomas Manley & Son, of this city, for erection of new main building for Ontario School for the Deaf. Work of excavation has started.

Belleville, Ont.—The Ontario Oakoal Co., Ltd., will erect and equip a plant to convert the city's garbage and waste material into fuel. Estimated cost, $40,000.

Big Valley, Alta.—Municipal Hospital Board plans erection of hospital. By-law will be submitted.

Brandon, Man.—Contract let to F. Lissaman for alterations to the post office to cost $6,000.

Brandon, Ont.—Tentative plans for a new fireproof building at the Brandon General Hospital have been prepared by Stevens and Lee, architects, Toronto.

Brantford, Ont.—A Roman Catholic hospital will be erected here.

Bridgeburg, Ont.—An issue of $50,000 debentures is being made for additions to the public school. Town clerk, R. A. Land.

Calgary, Alta.—City commissioners are considering the erection of a municipal abattoir.

Calgary, Alta.—Premier Charles Stewart, Edmonton, has notified Mayor R. C. Marshall that the construction of the new Normal School may be started this winter.

Calgary, Alta.—Contract let to A. B. Himmelman for alterations to building on Eighth Ave. for the Standard Agencies. Estimated cost, $5,000.

Chatham, Ont.—C. H. Crane, architect, Detroit, Mich., will prepare plans for the erection on King St., of a large theatre.

Chatham, Ont.—Negotiations have been reopened by the government with the directors of the Hotel Sanita, for the purchase of the building to be converted into a sanatorium for returned soldiers.

Chatham, Ont.—Additions are being constructed to the plant of the Canadian Fertilizer Co., and the mill of the T. H. Taylor Co.

Clyde, Alta.—Clyde Consolidated School District plans erection of school.

Dartmouth, N.S.—Imperial Oil Co. plans to enlarge its refinery here very shortly. An expenditure of approximately $1,000,000 will be involved in connection with the work. Chief engineer, Thos. Montgomery, 56 Church St., Toronto.

Edmonton, Alta.—Edmonton, Dunvegan & B.C. Railway plans additions to depot.

Edmonton, Alta.—Edmonton Public School Board and the University of Alberta plan erection of large school. President of University, Dr. Torn.

Edmundston, N.B.—A school costing $100,000 will be erected here next spring. Mayor, Mr. Michaud.

Elmira, Ont.—A movement is on foot by the Ladies' Patriotic League for the erection of a soldiers' memorial hospital.

Fort William, Ont.—Provincial government may build additions to the Industrial Experiment Station here. Architect of the Department of Agriculture, C. J. Govson, Parliament Buildings, Toronto.

Fort William, Ont.—Fire recently destroyed the city's car barns. The burned building was insured for $85,000, and the rolling stock for $195,000. Plans are under way for rebuilding the barns. Clerk, Alex. McNaughton.

Fraserville, Que.—New tenders will be called for addition to St. Joseph's Hospital. Cost, $100,000. Architect, Pierre Levesque, 115 St. John St., Quebec.

Guelph, Ont.—The Dominion Bank has purchased a site at the corner of Wyndham and Macdonnell Sts., and will erect a new building.

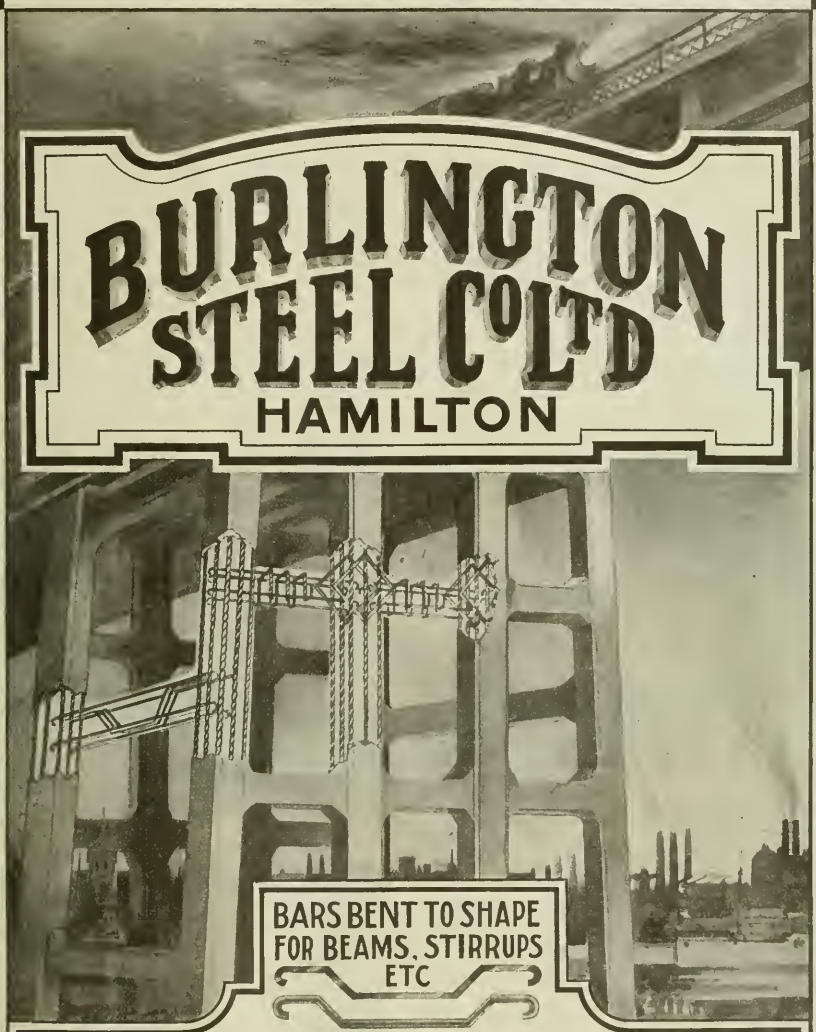
Guelph, Ont.—This year the local Housing Commission is erecting 24 houses at a total expenditure of $66,000, and next year it is hoped to build several hundred houses.

Hamilton, Ont.—A new branch post office is being erected on Barton St. Estimated cost, $40,000.

Hamilton, Ont.—The International Plow Works Co. will erect a $100,000 extension to its present large plant.

Hamilton, Ont.—The United Aircraft Engineering Corporation of New York has offered to erect and operate a municipal airdrome if the city will provide a site.

BURLINGTON STEEL CO LTD
HAMILTON



BARS BENT TO SHAPE FOR BEAMS, STIRRUPS ETC

STEEL BARS
FOR CONCRETE REINFORCEMENT
ROUNDS, SQUARES, TWISTED SQUARES, FLATS, ANGLES.

Kitchener, Ont.—The erection of an addition to the House of Refuge is being considered by the board of management.

Kitchener, Ont.—The Dominion Rubber System will start work immediately on the erection of a number of houses in Kitchener and Waterloo.

London, Ont.—A deputation will go to Ottawa to ask the government to build a new railway station.

London, Ont.—The London and Western Trust Co., Ltd., will shortly erect a new building on Richmond St.

London, Ont.—Tentative plans are being considered by the directors for the expansion of the arts departments of the Western University, including the erection of a new dormitory building.

London, Ont.—The board of governors of Western University appointed E. V. Buchanan, of the Utilities Commission, to superintend the erection of the new medical school building. Mr. Buchanan's services will be given gratis. The contract for the general construction work to cost $234,000, was awarded to John Puterbough. Bennett & Wright, of Toronto, were awarded the plumbing work at a cost of $70,000. The electrical work and painting have not yet been let. It is expected that the entire cost of the building, including furnishings, etc., will be $350,000.

Montreal, Que.—Building permit granted to the Alaska Bedding Co.., for the erection of a $200,000 building.

Moosomin, Sask.—The question of enlarging the Union Hospital is under consideration. Commissioner of Public Works for Saskatchewan, Dr. M. M. Seymour, Regina.

Nanaimo, B.C.—A movement is on foot here for the establishment of an isolation hospital. Medical health officer, Dr. Drysdale.

Newdale, Man.—The municipal council will be asked to submit a by-law to the ratepayers authorizing the erection of a municipal memorial hall.

New Toronto, Ont.—Lake Shore Road G.W.V.A. contemplate erection of memorial hall. Secretary, J. Neil, Box 206, New Toronto.

Ottawa, Ont.—The Swift Canadian Co. will erect a large warehouse on Besserer St.

Ottawa, Ont.—Public School Board plans additions to two schools. Chairman, R. W. Hamilton.

Owen Sound, Ont.—There is a strong probability that a large addition will be made to the Patterson Hotel in the spring. Proprietor, Mr. Douglas.

Quebec, Que.—Price Bros. & Co. will erect a large office building on St. Lawrence St.

Quebec, Que.—Sir William Price, president of Price Brothers and Co., has announced that the company will start work, without delay, on a large newsprint mill in the Saguenay district.

Raymond, Alta.—The Standard Bank of Canada has taken a lease on the front half of the King and Green Building for the purpose of converting it into a new branch office.

Rossland, B.C.—The Consolidated Mining and Smelter Co. contemplates the installation of a new concentrator, which will involve the outlay of at least a million dollars.

Sandwich, Ont.—The Fisher-Wilkie Foundry Co. proposes to build a $200,000 factory here.

Sarnia, Ont.—Tenders will be received by R. W. Fawcett, architect, up to noon, Tuesday, November 18th, 1919, for the erection of a public school building. Plans and specifications may be seen at the architect's office, 116½ Front St., Sarnia.

Saskatoon, Sask.—The local government board has given consent to the by-law authorizing the expenditure of $300,000 for an extension to the collegiate institute. The board also advised that additional equipment be allowed for at the same time, and included an extra $50,000 for this purpose.

Seaforth, Ont.—Ratepayers defeated the by-law for a soldiers' memorial and clubhouse.

Sherbrooke, Que.—The Cluett-Peabody Co. will locate a branch in this city.

Sherbrooke, Que.—The Walter Blue Co. propose to enlarge their factory.

St. John, N.B.—The Dominion government may proceed shortly with the construction of the new baggage and passenger shed and other facilities at West St. John docks, which will cost approximately $276,000. In addition, the extension of the grain conveyors to berth No. 15 has been recommended.

St. Jules, Que.—Quebec Central Railway plan erection of station. Manager, M. Walsh, Sherbrooke, Que.

St. Mary's, Ont.—Ratepayers defeated the by-law to provide $5,000 for a clubhouse for the returned men.

St. Thomas, Ont.—The Board of Trade will promote a campaign to raise funds for the erection of a memorial hospital. Secretary, Mr. Lodge.

Toronto, Ont.—The Fred Victor Mission, Queen and Jarvis Sts., will erect a new building at 341 Jarvis St.

Toronto, Ont.—Fire completely destroyed the sheds and garage of the Lambton Golf and Country Club. Loss, $16,500.

Toronto, Ont.—Holy Name parish, Danforth Ave. district, will erect a public hall on Carlaw Ave. Approximate cost, $25 000.

Toronto, Ont.—Board of Control decided to ask the Harbor Board to provide a site for a fire station in the Ashbridge's Bay industrial district.

Toronto, Ont.—The works committee approved the plans of the General Fire Extinguisher Co. for a factory on Dundas St. Approximate cost, $500,000.

Toronto, Ont.—Permit issued to the A. D. Gorrie Co. for the erection of a reinforced concrete garage at 354-60 Victoria St., at a cost of $80,000.

Toronto, Ont.—Permit granted for the erection by the Merchants Bank of Canada of a four-story granite, limestone and brick building at 12 King St. West. Estimated cost, $180,000.

Toronto, Ont.—Contract let to the Frid Construction Co., Ltd., 61 Adelaide St. E., for the erection of new building on east side of Yonge St., south of Shuter St., for the Adams Furniture Co. Approximate cost, $325,000.

Toronto, Ont.—Ten acres of the western section of the Hillcrest race track property have been purchased by the Prest-O-Lite Co., Ltd., corner Elm St. and Centre Ave., Toronto, for the erection of a large manufacturing plant.

Toronto, Ont.—The following building permits have been issued: Grand Trunk Railway, additional story to present building, Station Street, southeast corner York Street, $52,000. William Davies Co., alterations to building, 804 Yonge Street, $10 000.

Toronto, Ont.—Contract let to the John V. Gray Construction Co., Confederation Life Building, for reinforced concrete work on manufacturing building for Dunlop Tire and Rubber Goods Co., 244 Booth Ave. Estimated total cost of building, $250 000. Architect and engineer, B. H. Prack, Lumsden Building.

Toronto, Ont.—A $1,000,000 extension is being built by Baldwin's, Ltd., to the plant of the British Forgings Co., which they have acquired. The present buildings are also being refitted and equipped. A 125-ton power wheel is now being installed. Power will be secured from the Hydro-Electric Power Commission of Ontario.

Toronto, Ont.—Board of Control awarded the following contracts in connection with the erection of a new public lavatory building at Island Park: Masonry, Teagle & Son, price $6,176; plumbing and drainage, Crawford & Hodgson, $2,160; painting and glazing, R. G. Johnston; carpentering, F. J. Murphy, $4,440; electric wiring, Harris & Marson; plastering, John Boyce & Son.

Toronto, Ont.—John Catto & Son will spend $30,000 on improving the property at the corner of Yonge and Shuter Sts., to which building they will shortly remove. The store at present occupied by them on King St. has been purchased by the King Edward Hotel Co. for large extensions to that hostelry.

Best Known Cable Reel In Canada

THE demand for Northern Electric products and the fact that they are made by the largest manufacturers of bare and insulated wires and cables for electrical distribution is a positive assurance of quality.

They are as near perfection in both dependability and durability as experience, workmanship and superior materials, combined with the most modern machinery, can make them.

Bare copper, rubber covered and paper insulated, lead covered cables of Northern Electric manufacture—are designed by the most capable engineering skill and tested to ensure safety and efficiency to the fullest degree possible.

Our nearest House will be pleased to submit specifications and prices upon request.

Toronto, Ont.—Tenders, addressed to W. C. Wilkinson, secretary-treasurer, Board of Education, Administration Building, 155 College Street, will be received until Thursday, November 27th, 1919, for plastering, John Fisher School. Electric wiring, Bolton Avenue and Duke Street schools. Telephones, Jesse Ketchum and Queen Alexandra schools. Fresh air inlets, Perth Avenue and Harbord Street Collegiate Institute. Pipe covering, various schools. Plumbing, Bolton Avenue school. Specifications may be seen at the office of the Superintendent of Buildings, 155 College Street.

Trenton, Ont.—W. J. Carmichael, architect and engineer, 29 Hospital St., Montreal, will prepare plans for exchange office for Bell Telephone Co.

Vancouver, B.C.—The Canadian Northwest Steel Co. has taken out a permit for a crane shed to cost $6,500.

Vancouver, B.C.—The establishment of a curling rink is being considered. Publicity Commissioner, J. R. Davison.

Victoria, B.C.—The Dominion government plans are now ready and the necessary appropriation for construction has been made for the erection of the new offices of the Marine Department on the Songhees Reserve. The new building will cost between $50,000 and $100,000.

Victoria, B.C.—City council decided to adopt the federal Housing scheme, and to accept Victoria's $180,000 housing allocation.

Walkerville, Ont.—The school board requested the town council to grant $25,000 for the purpose of establishing a technical school.

Waterdown, Ont.—Council decided to submit a by-law in January next to raise $20,000 for the erection of a memorial hall. Clerk, J. C. Medlar.

Welland, Ont.—In his report to the city council, W. M. German, industrial commissioner, states that the following industrial companies are likely to locate plants in this city: McCaskey Systems, Ltd., Toronto; Smith & Sons, of Buffalo, manufacturers of wire specialties; a firm manufacturing high speed tools at Albany, N.Y., and an automobile concern.

Wentworth County, Ont.—County Council will consider erection of a new school in Saltfleet township. Reeve, T. J. Mahoney.

Weston, Ont.—Contract let to B. G. McCallum for erection of factory for McCallum, McLaren, Ltd. Cost, $3,000.

Windsor, Ont.—The Bank of Hamilton propose to erect a branch bank at the corner of Ouellette Ave. and Chatham St.

Windsor, Ont.—A site of 63 ft. on Wyandotte and Lincoln Avenues has been secured by the Imperial Bank of Canada, and next season a new branch building will be erected.

Winnipeg, Man.—Contract let to Gray & Davidson for erection of garage costing $25,000 for Grey-Ogletree Motor Co., 621 Wall St.

Winnipeg, Man.—Plans have been prepared by the provincial government for the erection of a deaf and dumb institute. Estimated cost, $600,000. Deputy Minister of Public Works, S. C. Oxton.

York Township, Ont.—Separate and bulk tenders for one or both of two eleven-roomed schools to be built in Fairbank near Eglinton Avenue and Vaughan Road, S. S. No. 15, will be received until November 25th, 1919. Contracts call for brick work, hollow tile, terrazzo floors, steel casement sash, carpentry work, electric work, plastering, painting, plumbing and heating, etc. Plans and specifications may be obtained at the office of S. B. Coon & Son, architects, 810 Excelsior Life Building, Toronto.

MISCELLANEOUS

Guelph, Ont.—The E. A. Lowry Power Equipment Co., Herald Building, has recently been incorporated under provincial charter with an authorized capital of $50,000. The company specializes in contracting for electrical power equipment for operating all manufacturing industries using electric motors, generators, transformers, etc., in the larger sizes. Contracts are held with the Canadian Westinghouse Co., Ltd., for supplying motors, etc., and with whom a large order for motors has just been placed. E. A. Lowry is president of the company.

Hamilton, Ont.—A by-law to raise $150,000 for the development of Scott Park as an athletic field and for improvements to Victoria and North End parks will be submitted to the ratepayers in January.

Hamilton, Ont.—Fire Chief A. B. TenEyck has recommended the installation of a new fire alarm system at an estimated cost of $10,000. A by-law may be submitted to the ratepayers in January.

Lakefield, Ont.—Tenders, addressed to J. W. Pugsley, secretary, Department of Railways and Canals, Ottawa, and endorsed, "Tender for Rebuilding Dam at Lakefield, Trent Canal," will be received until 12 o'clock noon on Saturday, November 29th, 1919. Plans and specifications may be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Trent Canal, Peterborough, Ont.

Levis, Que.—The newly formed National Shipbuilding Co. has taken over the old-time Veilleux shipyards here and will build at least fifteen large vessels for which contracts have been secured.

Naramata, B.C.—Contract let to S. Mills, New Westminster, by Dominion government, for construction of wharf.

North Vancouver, B.C.—Contracts for two steel steamers of 8,350 deadweight tons each have been awarded to the Wallace shipyards, North Vancouver, by the Dominion government. Work will commence immediately.

Ottawa, Ont.—Incorporation has been granted to the following joint stock companies: Electric Machinery Co., Ltd., Montreal, capital $100,000; Rex Oil Burner, Ltd., Montreal, $50,000; Frontenac Construction Co., Ltd., Quebec, $75,000; Canadian Coal Briquette & Liquid Fuel Co., Ltd., Montreal, $70,000; St. Lawrence Dock & Shipbuilding Co., Ltd., Levis, $100,000; the American Fuel Co., Ltd., Toronto, $100,000.

Portage la Prairie, Man.—On December 16th next, by-laws calling for the issuance of debentures will be submitted to the ratepayers as follows: City hall and community building, $100,000; waterworks, $12,000; electric light, $16,000. Clerk, W. R. Grieve.

Queensville, Ont.—The council of East Gwillimbury have instructed the E. A. James Co., Ltd., Toronto, to prepare plans for the drainage of a section of the Holland Marsh. The first area reclaimed will comprise some 6,000 acres, and the work contemplated includes a 12-foot dike, bridges and a pumping plant to keep the water in this area some two feet lower than Lake Simcoe.

St. John, N.B.—Debentures will be issued to the amount of $389,000 for various local improvements as follows: Waterworks, $318,500; wharf repairs, $33,500; roads, $37,500. City engineer, G. N. Hatfield.

The Pas, Man.—Dominion government let contract to M. J. Wylie and L. Perry, Winnipeg, for construction of wharf.

Vancouver, B.C.—Dominion government will prepare plans and specifications, and call for tenders for the construction of a large pier on Burrard Inlet. Plans are also being prepared for two steamers for service from Vancouver, Victoria and Seattle, and tenders will be called for these ships from Canadian shipyards.

Vancouver, B.C.—Tenders will be received by F. H. Shepherd, Superintendent of Dredges, Department of Public Works, Canada, Vancouver, B.C., until 4 p.m., on Monday, November 24th, 1919, for repairs and general overhaul of the Departmental Dredge No. 303 ("Fruhling"). Specifications may be seen at the offices of A. F. Mitchell, Acting District Engineer, Victoria, B.C.; C. C. Worsfold, District Engineer, New Westminster, B.C., and of F. H. Shepherd, 710-713 Birks Building, Vancouver, B.C.

Victoria, B.C.—H. M. Davey, engineer, Public Works Department, Ottawa, was in this city recently and looked over the plans for the proposed new drydock for Victoria. Mr. Davey took the borings of the proposed site, and stated

"A valuable publication for the municipal engineer."—*American City*

Waterproofing Engineering

For Engineers, Architects, Builders, Roofers and Waterproofers

By JOSEPH ROSS, B.S., C.E., Waterproofing Engineer.

Covers very thoroughly the subject of the need and function of waterproofing, systems of waterproofing, impervious roofing, waterproofing expansion joints in masonry, waterproofing materials, implements and machinery, technical and practical tests on waterproofing and cost data.

Architects and contractors, as well as engineers engaged in construction work, will find this book a valuable work of reference.

x+442 pages. 6 by 9. 138 figures. Cloth, $5.00 net.

"Considered as a standard of its kind"

Automatic Sprinkler Protection

Second Edition

By GORHAM DANA, S.B., Manager The Underwriters' Bureau of New England.

The above reference to Mr. Dana's book was made by the National Fire Protection Association. The work, as a matter of fact, is most interesting and instructive to any student of automatic sprinkler protection. The new edition has been thoroughly revised, information on many new devices being added. It is the most complete work of the kind on the market.

vii+443 pages. 5¾ by 8¼. 349 figures. Cloth, $3.50 net.

"A well-arranged encyclopedia of information"

Kidder's Architects' and Builders' Pocket Book

By the late FRANK E. KIDDER. Sixteenth Edition by THOMAS NOLAN, Editor-in-Chief, and a staff of specialists.

Presents in condensed form the knowledge and experience of a score of experts in every phase of building design and construction. Information is given on all classes of frame, masonry, steel and concrete structures. In all, this book should be on every architect's and builder's desk for constant reference.

xxiii+1816 pages. 4¼ by 7. Flexible binding, $6.00 net.

that he expected construction work would begin at an early date.

Walkerville, Ont.—Bell Telephone Co. will erect a new exchange building here early next year. In addition to this development the company proposes to erect cables on every street, replacing the wires which now serve in many cases. The estimates call for an expenditure of between $150,000 and $200,000 on this cable scheme. The plans also call for much underground work. A new switch board will also be installed in Windsor.

Woodstock, Ont.—Tenders, addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Friday, November 21st, 1919, for Woodstock, Ont., post office fittings. Plans and specifications may be seen at the offices of the Chief Architect, Department of Public Works, Ottawa; the Caretaker, Public Building, Woodstock, Ont., and the Superintendent of Dominion Buildings, Postal Station "F," Yonge Street, Toronto, Ont.

Tenders Called For

HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO

RAILWAY DEPARTMENT

SUPERSTRUCTURE OF HIGHWAY BRIDGE ACROSS WELLAND RIVER AT CHIPPAWA, ONTARIO

ADVERTISEMENT FOR TENDERS

Sealed tenders will be received until November 28th, 1919, at 12 o'clock noon, addressed to Sir Adam Beck, Chairman, Hydro-Electric Power Commission of Ontario, 190 University Avenue, Toronto, Ontario, and marked "Tender for Chippawa Highway Bridge." Plans, specifications, and other information may be obtained by applying to the office of Chief Engineer. The Commission reserves the right to reject any or all tenders received.

Hydro-Electric Power Commission of Ontario.

W. W. POPE,
Secretary.

Dated at Toronto, November 14th, 1919. 375

ESSEX BORDER UTILITIES COMMISSION

Proposals will be received by the Essex Border Utilities Commission until November 27th for completing the South Sewage Interceptor in Sandwich and Ojibway, Ont.

The work consists of laying approximately the following lengths of reinforced concrete lock-joint pipe in four-foot lengths, which is now on the work.

42" diameter—16'
39" " —4360'
27" " —4320'

Building fifteen (15) concrete and brick manholes and setting cast-iron frames and covers; pumping and clearing out four thousand (4,000)feet of existing sewer 42" and 27" in diameter, and shaping up ditches; replacing 80 sq. yds. of concrete street pavement.

The depth of the excavation is approximately 13—15 feet consisting of sand and clay.

The work lies along a concrete-paved roadway, and is readily accessible. The contractor will be required to furnish suitable pumping equipment.

Plans and specifications may be obtained at the office of Morris Knowles, Ltd., 66 Ouellette Ave.

Essex Border Utilities Commission.

GORDON McGREGOR, Chairman. W. J. BAXTER, Secretary. 374

Condensed Advs.

Advertisements under this heading at following rates per insertion, with fifty cents per insertion as minimum rate in any case; "Positions Wanted," one cent per word; all other condensed advertisements, three cents per word. Payable in advance; 50 per cent. extra if charged.

GENERAL SUPERINTENDENT wanted for hydraulic construction. Must be able to take complete charge. Reply stating age and experience. Box 23, *The Canadian Engineer*, Toronto.

DRAFTSMAN WANTED.—Good general draftsman used to designing and drafting. State experience and salary expected. William Hamilton Company, Limited, Peterborough, Ont. 379

WANTED.—Engineer-draftsman, 18 years' experience, Structural Steel, Plant Design and Maintenance, desires position of responsibility, executive or otherwise. Box 21, *Canadian Engineer*, Toronto.

ENGINEER.—Research Mechanical Engineer, with very best education and experience as such wanted by Pulp and Paper Manufacturing Plant. State education, experience, age, married or single, and salary asked for. Also send copies of references. Only very best men need apply. Box 25, *The Canadian Engineer*, Toronto.

MANUFACTURER in Eastern Townships, having good facilities and considerable experience in the production of a wide variety of machinery lines, desires to undertake the manufacture (for the Canadian or export trade) of American or English machinery. Full particulars gladly upon request. Box 396, *Canadian Engineer*, Toronto.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian patent No. 179286, granted September 11th, 1917, to Whitmore Brothers, Corporation of Cambridge, Massachusetts, U.S.A., for box, may do so upon application to the undersigned, who are prepared to supply all demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh & Co., 5 Elgin Street, Ottawa, Canada; Russel S. Smart, resident. 377

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian patent No. 180382, granted on November 13th, 1917, to the L. Moore Dry Kiln Company, assignee of Chas. J. Williams, Jr., both of Jacksonville, Florida, U.S.A., for hanger, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention, and from whom full information can be obtained. A Weekly Paper for Civil Engineers and Contractors

Analysis of Concrete-Proportioning Theories

Data Upon Which Abrams' Fineness Modulus and Edwards' Surface Area Methods Are Based Show Validity of Water-Cement Ratio Theory and Demonstrate That Fineness Modulus Varies With Surface Area—Tests All Agree But Interpretations Differ

By RODERICK B. YOUNG

Engineering Materials Laboratory, Hydro-Electric Power Commission of Ontario

IN the last eighteen months, much new information has been published on the laws underlying concrete mixtures, and at least two different methods of proportioning based on this new data have been proposed. These two methods, the "fineness modulus method" of Prof. Duff A. Abrams, and the "surface area method" of Lewellyn N. Edwards, have been described in detail in *The Canadian Engineer*. The two methods would seem to be conflicting. The discussion both for and against, which the publication of these methods has occasioned, and the direct contradiction of their basic principles made by the engineers of the Bureau of Standards, has further tended to strengthen this impression and to obscure the fact that the published data of the different parties to this controversy, if not the conclusions derived therefrom, are in striking agreement.

Prof. Abrams' method is based primarily upon a relationship which he has discovered between the compressive

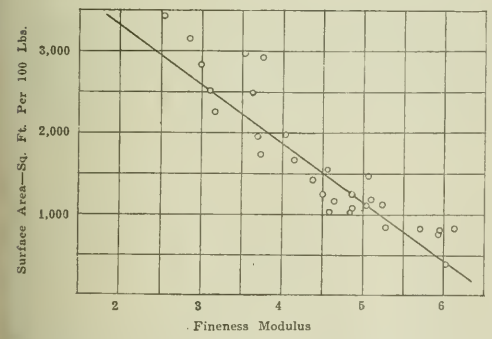

FIG. 1—RELATION BETWEEN FINENESS MODULUS AND SURFACE AREA OF GRADED AGGREGATES (FROM H. E. P. C. TESTS)

strength of a concrete and the ratio between the volume of water and volume of cement used in producing it. He claims that for given concrete materials, the strength depends on only one factor, the ratio of water to cement, called for convenience the water-cement ratio, that this relation holds so long as the concrete is workable, and that the character of the aggregate makes little difference so long as it is clean and not structurally deficient, and so long as proper account is taken of differences in their absorptive qualities. From this he concludes that the size and grading of the aggregate, and the quantity of cement, are of no importance except in so far as these factors influence the quantity of mixing water required to produce a workable concrete.

The fineness modulus of an aggregate is obtained from its sieve analysis. The percentages of material coarser than each of the sieves used, is summed and the result divided by 100. Prof. Abrams has standardized on a particular set of sieves, the basic sieve of which is the No. 100, having a sieve

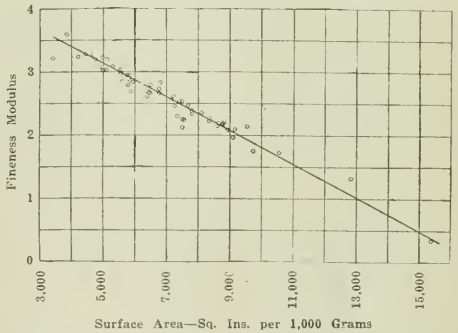

FIG. 2—MR. EDWARDS' DIAGRAM SHOWING RELATION BETWEEN SURFACE AREA AND FINENESS MODULUS

opening of 0.0058 in. In each succeeding sieve of the series, the opening is double the width of the preceding one.

Prof. Abrams claims that this fineness modulus enables one to interpret properly the sieve analyses of an aggregate, and that all aggregates of the same fineness modulus require the same quantity of water to produce a mix of the same

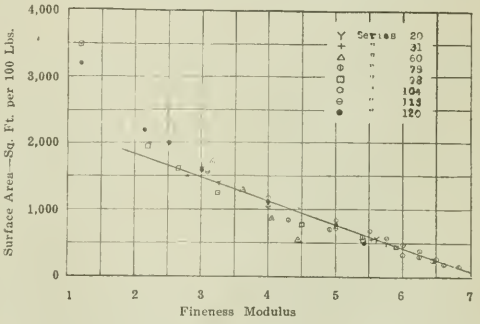

FIG. 3—RELATION BETWEEN FINENESS MODULUS AND SURFACE AREA—DERIVED FROM RESULTS OF PROF. ABRAMS' TESTS

plasticity and to give concrete of the same strength, so long as the aggregate is not too coarse for the quantity of cement used. This, he says, is because the fineness modulus simply reflects the changes in water-cement ratio necessary to produce a given plastic condition.

Mr. Edwards' method is based on the theory that for uniform plasticity and uniform strength, the cement varies

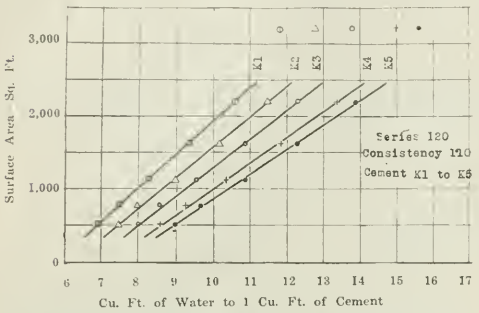

FIG. 4—RELATION BETWEEN MIXING WATER AND SURFACE AREA TO GIVE CONSTANT PLASTICITY (DERIVED FROM PROF. ABRAMS' TESTS)

as the surface area of the aggregate; and further that the quantity of water required to produce mortars of uniform consistency is a function of the water required to reduce the cement to a "normal" paste and of the surface area of the sand particles to be wetted.

In other words, Mr. Edwards claims a relation between strength and surface area, and between mobility and surface area and his tests support his theories so far as mortar mixtures are concerned. Later tests by the Hydro-Electric

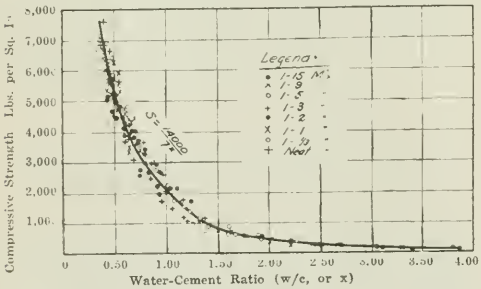

FIG. 5—PROF. ABRAMS' DIAGRAM SHOWING RELATION BETWEEN WATER-CEMENT RATIO AND STRENGTH OF CONCRETE

Power Commission of Ontario, under the direction of the writer, show that these conclusions are equally applicable to concrete mixtures.

Mr. Edwards obtains the surface area of an aggregate by counting and weighing some of each size of aggregate obtained in a sieve analysis, and from this data determining the average number of particles per unit weight for each size. Then, assuming these to be spherical, and knowing their specific gravity, he calculates the average volume per particle, the surface area per particle, and hence the total surface area per unit weight for each size of separation.

The surface area of any mixed material can be found by multiplying the surface area per unit weight of each size of separation by the weight of that size present in the material, and adding these. The value thus obtained is not the true surface area, for the latter cannot be obtained, as the particles are not true spheres, are variable in shape and have not smooth surfaces. However, this value undoubtedly bears a constant relation to the true surface area, and for all practical purposes is equally as useful.

The Bureau of Standards, Washington, D.C., made a limited series of tests to check the findings of these investigators. As a result the Bureau claims that the water-cement ratio is only an incidental relation of no direct value to the engineer in proportioning concrete, that a wide difference in strength is found with constant water-cement ratio and that there is no relation between surface area and strength. These conclusions directly contradict the findings of the two last-mentioned investigators.

At a later time, however, the Bureau makes this interesting statement: "Our tests indicate that for constant flow-

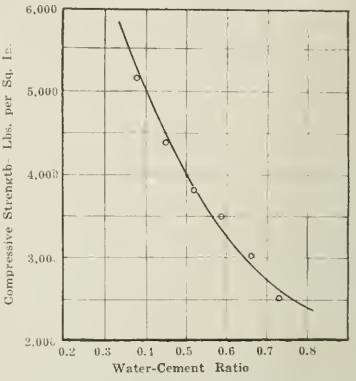

FIG. 6—RELATION BETWEEN WATER-CEMENT RATIO AND STRENGTH OF CONCRETE (PLATTED FROM MR. EDWARDS' TESTS)

ability the water required varies with the surface area of the aggregate."

Other investigators are working upon these different theories, although their results have not yet found their way into print. Prof. A. N. Talbot, of the University of Illinois, has said of his investigations, carried out upon concretes of one consistency and cement content:—

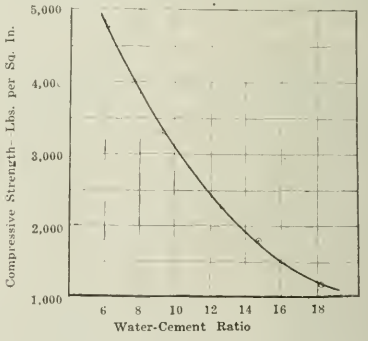

FIG. 7—RELATION BETWEEN WATER-CEMENT RATIO AND STRENGTH OF CONCRETE (PLATTED FROM BUREAU OF STANDARDS' TESTS)

"The tests indicate that for an aggregate having a given size of particles, the amount of mixing water required to produce a concrete of a given consistency, or mobility, is equal to a constant plus a term which is dependent upon the surface area. The tests show that the strengths of these con-

cretes, made up to have the same mobility, are also dependent upon the surface area. Concretes having the same water-cement ratio give nearly the same strength through a part of the range of water-cement ratio values, but for each maximum size of particle, the results diverge from the main curve,—this occurring at places along the curve which vary with the maximum size of particle and which are quite far apart."

The Hydro-Electric Power Commission of Ontario has been conducting investigations along similar lines. Some of the conclusions so far reached are:—

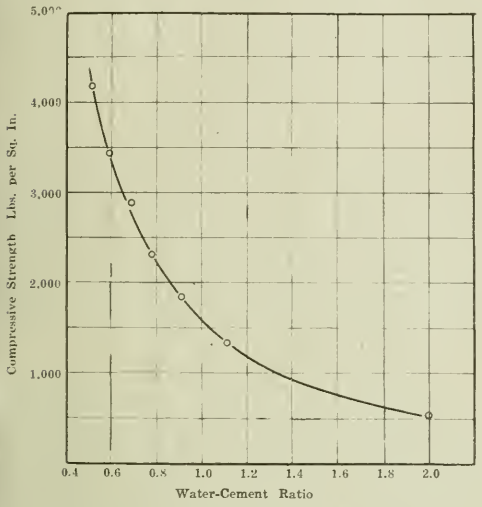

FIG. 8—RELATION BETWEEN WATER-CEMENT RATIO AND STRENGTH OF CONCRETE (H. E. P. C. TESTS)

1. That the fineness modulus is but another and somewhat approximate method of defining the surface area.

2. That within the range of workable mixtures, both the "strength" and "water required to bring a mixture to a uniform degree of plasticity" vary with the surface area, the relation being actually that described by Messrs. Talbot and Edwards.

3. That there is a fixed relation between water-cement ratio and strength for mixtures of the same cement, same aggregate and same age.

Fineness Modulus and Surface Area

Fig. 1 shows the relation found when the fineness moduli of mixed aggregates are platted against their surface areas as determined by the Edwards method.

This figure is similar to one given by the writer in *The Canadian Engineer*, June 26th, 1919, issue, except that it covers materials from dust to 1½ ins., while the former included only sands graded from dust to ¼ in. In the article just referred to, algebraical expressions for both the fineness modulus and surface area were derived, and it was shown that no mathematical relation exists between them. While an infinite number of values of fineness modulus may be found for any one value of surface area, and vice versa, yet it is a remarkable fact that for the materials ordinarily encountered, fineness modulus varies approximately with the surface area.

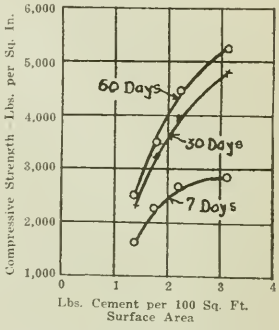

FIG. 12—RELATION BETWEEN CEMENT CONTENT AND COMPRESSIVE STRENGTH (PLATTED FROM MR. EDWARDS' TESTS)

Figs. 2 and 3 show similar curves obtained from the data of Mr. Edwards and Prof. Abrams, respectively.

Fig. 2 was reported by Mr. Edwards in *The Canadian Engineer* for October 9th, 1919, while Fig. 3 was worked up from Prof. Abrams' published results, and includes materials graded from 0-No. 28 sieve to 0-1½-in. sieve, a wider range than is included in either Figs. 1 or 2.

The relationship is probably the explanation of the reason that Prof. Abrams has found fineness modulus to be a measure of the effective size and grading of the aggregate.

Consistency and Surface Area

Prof. Talbot's conclusion that the water in concretes of equal cement content, necessary to produce a concrete of a given consistency, is equal to a constant plus a term which

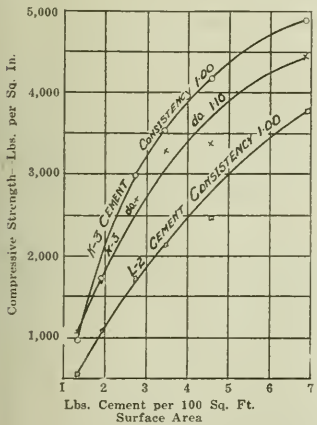

FIG. 9—*Derived from Prof. Abrams' Tests*

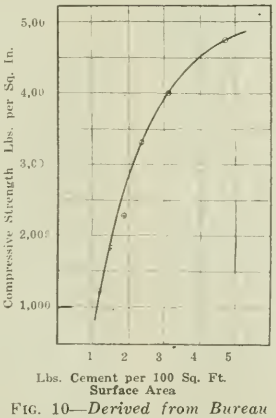

FIG. 10—*Derived from Bureau of Standards' Tests*

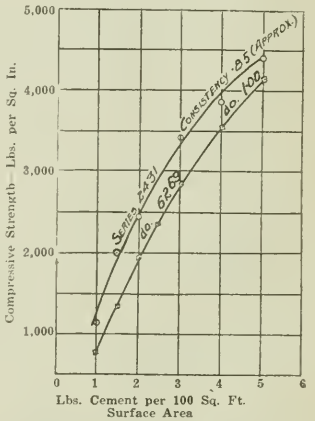

FIG. 11.—*H. E. P. C. Tests*

RELATION BETWEEN CEMENT CONTENT AND COMPRESSIVE STRENGTH OF CONCRETE

is dependent on the surface area, is the same conclusion arrived at by Mr. Edwards in his study of mortars. The writer's studies of both theoretical and experimental data corroborate this conclusion. The engineers of the Bureau of Standards confirm this partially when they state that their tests indicate that for constant flowability the water required varies with the surface area of the aggregate. Prof. Abrams uses his fineness modulus to proportion mixtures to a given consistency, and to do this uses a formula in which the water required is the sum of a quantity dependent on the amount of cement used and a quantity varying with the fineness modulus. Assuming fineness modulus to be another way of stating surface area, or vice versa, it is evident that the work of each of these investigators point to the same end.

Unnecessary to Make Assumption

It is, however, unnecessary to make the foregoing assumption to show that Prof. Abrams' results bear proof of this relation between mixing water and surface area at a given consistency. Fig. 4, which was worked up from the data in his paper* on "Effect of Fineness of Cement," shows five series of mixtures in which cements of different fineness were used, each proportioned 1:4 by volume with six different aggregates of a wide range in grading. The mixtures were all gauged to a uniform consistency, the water to do this being determined by means of Prof. Abrams' water formula. It is a striking confirmation of the law outlined in the last paragraph, that in the case of each of the different cements, when the amount of mixing water used is platted against the surface area of the aggregate in the mixtures, five of the six points lie on a straight line. The sixth point represents a mixture in which the material was a very fine sand, 10% of which was dust or silt. Under these conditions it is hardly to be expected that this point would agree with the other and more usual materials, because our means of determining equal mobilities are not such as to function accurately under these conditions.

The results of Fig. 4 cannot be explained by the fact that the surface area and fineness modulus have approximately a linear relation, for in the series represented (see Fig. 3, Series 120), this relation is a slight curve.

Water-Cement Ratio and Strength

Fig. 5, taken from the article by Prof. Abrams which was published in *The Canadian Engineer* for June 6th, 1918, shows the general relation found by Prof. Abrams between compressive strength and water-cement ratio. This curve covers an extremely wide range of mixtures, materials and consistencies. Fig. 6 is platted from the results of Mr. Edwards' mortar tests and show a similar relationship for the range covered by his tests. In these tests the proportions were constant, but the consistency varied. Fig. 7 is platted from data published by the Bureau of Standards from tests in which the consistency was nearly uniform, but in which the proportions varied. Fig. 8 is a similar series, carried out by the writer in the laboratories of the Hydro-Electric Power Commission of Ontario. Similar curves have been obtained in the same laboratory where the proportions were constant and the consistency varied. In all of these curves the mixtures used were plastic. The relationships are practically identical in each of these figures, showing very good agreement on this point.

Prof. Abrams has shown that for given materials and age, approximately equal strength will be obtained even with widely different grading of aggregate and consistency, provided that the mixtures are plastic and that the grading is not too coarse for the quantity of cement used.

Mr. Edwards in his early tests on surface area proved the same things, for he varied both the cement and water according to the surface area and obtained a constant water-cement ratio, and his mortar mixtures were of nearly equal strengths.

It is hard to reconcile the Bureau of Standards' claim that "a wide difference in strength is found with constant water-cement ratio even with the same aggregate and cement," unless it is that these tests were designed to give unusual conditions.

Prof. Abrams, in commenting on the Bureau's tests, has said of the aggregate used: " Over 40% of the aggregates were too coarse for the quantity of cement used; 26% of the mixes were too dry; 21% were both too coarse and too dry; 72% of the aggregates were of freakish grading." The writer agrees with Prof. Abrams' criticism, and considers this to be the explanation of the unusual results obtained.

It is interesting to note that Fig. 7, drawn from data obtained by the Bureau of Standards before the controversy arose, while not bearing upon the disputed question of equal water-cement ratios having equal strengths, shows that a consistent relationship is being obtained in this laboratory for commercial aggregates and plastic consistencies.

Surface Area and Strength

If, for workable mixtures of similar materials, a given strength concides with a fixed water-cement ratio, then it is evident that if the quantity of water required to bring a concrete mixture to a uniform degree of plasticity is a function of the surface area of the aggregate, the quantity of cement required to maintain this fixed water-cement ratio is likewise a function of surface area.

Conversely, if a fixed plasticity is maintained, and the cement content of the mixtures are constant, then the compressive strength varies with the surface area of the aggregate. Both of these points have been brought out nicely in the tests by Mr. Edwards.

Compressive Strength and Cement Content

In the writer's article published in the June 26th, 19 issue of *The Canadian Engineer*, the form of the theoretical relation between compressive strength and the cement content of a mixture was derived. The cement content was given in terms, of "pounds of cement per 100 sq. ft. of surface area," a unit which has been adopted by the Hydro-Electric Power Commission in all of its work. Figs. 9 to 12 show curves of the same form obtained from the experimental data of the investigators referred to, with the exception of Prof. Talbot. In the case of the tests of Figs. 9 and 12, the original results were obtained by other than the surface area method of proportioning. These curves are strikingly similar and are further evidence of the agreement between the data of the different investigators.

It is not within the scope of this article to discuss the relative merits of either the fineness modulus or the surface area methods of proportioning. Enough has been brought out, the writer believes, to show that they are simply different adaptions of essentially the same data.

Shortcoming of "Fineness Modulus"

The fineness modulus method of evaluating an aggregate has one serious shortcoming not present in the surface area method: It is dependent upon the number and sizes of the sieves used in its determination.

The surface area method is not so dependent; the same result can be obtained with any one of the commercial series of sieves in common use, because the surface area of an aggregate is a property of the material and not of both the material and the size and number of the sieves used in the sieve analysis.

A modification of Mr. Edwards' surface area method is being successfully applied by the Hydro-Electric Power Commission in the construction of several of its power developments. It is working satisfactorily and is giving better concrete with less cement than is being obtained on work where it is not in use. It is simple, and has been found easy to introduce into the field. It is not a panacea for all the ills of concrete, and its successful use requires careful inspection, intelligent supervision and a certain amount of laboratory assistance, but these are necessary with any method if good concrete is to be produced. It can be made to do all that is claimed for the "fineness modulus method," and it has certainly been found simpler to "put over" in actual field work.

*Presented June, 1919, before the American Society for Testing Materials; see *The Canadian Engineer*, November 6th, 1919, issue for summary of this paper.

Letters to the Editor

EFFECT OF RODDING CONCRETE

Sir,—Prof. F. E. Giesecke's tests on rodded concrete, reported in your August 14th issue, are of interest in showing the increased strength due to this treatment, and in illustrating the extent to which fresh concrete may be disturbed without adversely affecting its strength. The author properly attributes the increase in strength to the removal of the excess water by rodding.

The writer believes, however, that Prof. Giesecke is not on safe ground when he compares his tests directly with certain results from this laboratory, and depends on that comparison for a measure of the effect of rodding when using concrete of different consistencies. It is unfortunate that he did not make a parallel group of tests from which the water-ratio strength relation could have been platted for the unrodded concrete. (The water-ratio is the ratio of the volume of water in the batch to the volume of cement, considering cement to weigh 94 lbs. per cu. ft.) The strength of his concrete was probably different from ours, due to many factors which had no relation whatever to the effect of rodding. In other words, in his Fig. 1 the water-ratio strength curve for unrodded concrete may have been entirely different from the curve shown (which is based on certain of our tests), due to differences in the quality of the cement, temperature, curing conditions, time of mixing, or numerous other variations which affected all tests alike. The comparison of his earlier tests with our curve is not very convincing.

In our discussions of the water-ratio strength relation for concrete, we have pointed out that the constants in the formula quoted by Prof. Giesecke ($14{,}000/7^R$ where R is the water-ratio, an exponent) depend on the quality of the cement, age of concrete and other conditions of the test.

Other tests made in this laboratory give different values of these constants, although the general relation between water-ratio and strength has been found to hold true for different proportions of given materials so long as the concrete has water enough to make it plastic and the aggregate is not too coarse for the quantity of cement used.

Prof. Giesecke's Error

Prof. Giesecke has fallen into an error in plotting his tests in Fig. 1, since no allowance was made for the reduction in the water-ratio of the concrete as a result of rodding, due to one or more of the following factors:—

1. Working water to the surface, which escaped, and consequently did not influence the final water-ratio.
2. Evaporation due to long exposure of the cylinder during rodding.
3. Absorption of water by the aggregate during rodding.

Concrete which was originally mixed with a water-ratio of 1.00, may after rodding have a water-ratio of 0.7, consequently the strength should be platted with reference to the latter figure and not the former. In other words, the curves from Prof. Giesecke's tests should all be moved to the left, the exact position being unknown on account of the uncertain effect of rodding on the final water-ratio. If this were done, we would find a very different relation from that given by the original figure, and at the same time attribute the increase in strength to the proper cause; that is, the artificial reduction in the water-ratio.

The time of setting of the cement used in Prof. Giesecke's tests would have been of interest. Undoubtedly the plastic condition was quite different for the concrete which had been rodded for long periods than at the beginning. This should be borne in mind in considering applications of this method. It seems probable that the strength would have been quite similar had the concrete been permitted to stand for the periods shown, before being placed in the forms, provided that sufficient water were used in the beginning to provide a plastic mix after the absorption and evaporation had occurred.

In a series of tests carried out by the writer several months ago, a study was made of the effect on the strength of the concrete of using different methods of moulding the specimen. We were interested only in methods which could be used in moulding test cylinders in the laboratory. Compression tests were made on 6 by 12-in. cylinders at the age of 28 days, using sand and pebbles graded up to 1½ in. A 1: 5 normal consistency mix was used, with a water-ratio of 0.87. For 12 strokes of the ⅝-in. steel bar on each 4-in. layer of concrete, we secured a strength of 2,680 lbs. per sq. in.; for 25 strokes, 2,780; and for 50 strokes 2,810; an increase of about 4% for 25 strokes as compared with 12, and an increase of about 5% for 50 strokes as compared with 12.

The first and third values were the average of 5 tests; the second, the average of 15 tests made on different days. Puddling was done during the moulding of the specimen and the concrete was not subsequently disturbed.

Water-Ratio Determines Strength

These tests showed a comparatively slight effect due to the different number of strokes used on each layer. Twenty-five strokes for each 4-in. layer is the number regularly used in making our test pieces. It will be noted that the water-ratio of this concrete was not changed, consequently we would expect little effect due to the number of strokes, so long as the minimum number of strokes gave compact concrete. Several methods of tamping were also used. The same series covered a study of the effect of vibration, jigging and pressure. These tests brought out clearly that the increase in strength due to pressure on fresh concrete may be measured by the quantity of water which is forced out by the pressure. In other words, *it is the reduction in the water-ratio of the concrete which increases the strength.*

It is the writer's belief that much of the effect due to workmanship in handling and placing concrete can be traced to the influence of any particular practice on the final water-ratio of the mixture.

DUFF A. ABRAMS,
Professor-in-Charge,
Structural Materials Research Laboratory,
Lewis Institute.

Chicago, Ill., November 22nd, 1919.

EFFECT OF WATER UPLIFT ON OVERTURNING OF DAMS

Sir,—Replying to your comments in your issue of November 6th, regarding article on "Effect of Water Uplift on Overturning of Dams," the writer wishes to make a few explanatory remarks.

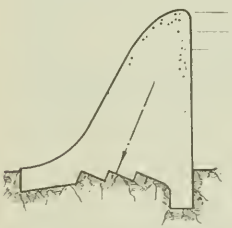

FIG. 1—GRAVITY DAM, ROCK FOUNDATION

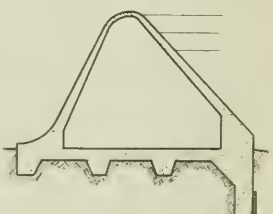

FIG. 2—REINFORCED HOLLOW DAM, EARTH FOUNDATION

Safety against sliding can be provided for in several ways: (1) Roughening between surfaces of contact; (2) increase in weight; (3) anchoring, by means of anchoring walls; (4) any combination of above.

Fig. 1 shows gravity dam section with rock surface roughened so that stability against sliding depends on shearing strength of concrete or rock.

Fig. 2 shows hollow reinforced dam section on earth foundation provided with toothing and anchoring wall. This method is comparatively new and has been described fully in the transactions of the American Society of Civil Engineers, December, 1917, in the article on the "Reconstruction of the Stony River Dam."

In both cases, Figs. 1 and 2, no concrete has been added to the amount required for stability against overturning, except in that in the second case a small amount of concrete was added to form toothing and anchoring wall. Inasmuch as this anchoring wall is merely an extension of a cut-off wall, but heavily reinforced and thicker, it serves two purposes—namely, (a) safety against sliding; and (b) increase in percolation distance in conjunction with sheet piling.

E. MAERKER.

Jackson, Mich., November 21st, 1919.

ECONOMIC STATUS OF GUARANTEES FOR PAVEMENTS ON ROADS AND STREETS*

THIS committee has very carefully considered the points brought up in the discussion of its progress report† during the annual convention held in New York, February, 1919, and in the technical press thereafter. It feels that certain of the criticisms of its report were based upon an incomplete understanding of its aim and scope, but realizes the difficulty of discussing a subject of this kind after listening to the reading of a somewhat lengthy and comprehensive report without having had opportunity to study it thoroughly

It has been suggested that it would be helpful if the committee were to indicate what it considers a proper period of reasonable life without repairs for various kinds of pavement under different conditions. An earnest effort to compile such a table, which would cover all possible conditions, clearly showed however that the wide variation necessary in a general schedule would render the figures worthless and would probably lead to a very heated discussion as to whether the figures cited were to be regarded as a measure of the life of various types of pavement when laid upon different kinds of foundations and subjected to traffic of various densities, and the attempt was therefore abandoned. Each set of conditions must be given individual consideration, and the committee believes that the determination of such reasonable periods in any particular case would not be extremely difficult and that any competent engineer can do this satisfactorily.

The committee's recommendation that the guarantee bond be supplemented by a cash retainer was based largely upon the difficulty sometimes experienced in having necessary repairs made within a reasonable time and was designed to provide a means of enforcing this necessary provision of any paving contract without first having to resort to a lawsuit. As a rule, a municipality has no fund available for this class of work and the cash retainer therefore serves two purposes:—

1. It tends to bring the contractor back to make the repairs, as he knows he will collect some money toward the expense involved.

2. It gives the municipality cash with which to make the repairs and thus avoids the necessity of going through the formalities and oftentimes difficulties of securing an appropriation, with all the attendant delays.

In this connection the committee recommended that a greater percentage be retained on resurfacing work as compared with new construction, in order to provide for approximately the same amount of retained money per square yard of finished pavement in both cases. This did not mean, as was assumed by some members, that the committee felt that resurfacing work, properly conducted, involved any greater guarantee liability than new construction work. On further consideration of the matter, your committee believes that reasonably adequate protection would be assured to the municipality by a reduction of the amount of the retained moneys from 10% to 20%, as at first recommended, to 5% and 8%, respectively. It further feels that such a provision cannot be justly held to be a curtailment of a contractor's working capital.

Fifteen Cents Per Square Yard

In arriving at this conclusion, your committee takes the position that fifteen cents per square yard to cover guarantee liabilities may be assumed as a fair average. On this basis the following figures may be considered as typical and illustrative of the principle involved:—

	Resurfacing.	New work.
Construction cost per sq. yd.	$1.50	$2.50
10% profit	.15	.25
Guarantee	.15	.15
Total	$1.80	$2.90
Retained (8%)	.15	(5%) .15
Payment on completion	$1.65	$2.75

In both cases the contractor receives a payment equal to his construction cost plus profit, the municipality retaining an amount practically equal to the sum included by the contractor in his bid as necessary to cover the guarantee provisions. This amount per square yard is the same for both types of construction and has not been expended by the contractor in his work and will not be expended by him except where defects in construction have occurred. While held by the municipality, the contractor will be paid interest on it. This amount, while sufficient to cover ordinary defects in workmanship and insure the making within a reasonable time of necessary repairs, is totally insufficient to cover extensive repairs rendered necessary by serious defects or failure of the work, protection against this being assured by the guarantee bond.

Your committee further believes that the criticism that its provision as to forfeiture of all retained moneys in case of failure to make ordered and necessary repairs is too drastic, is well founded and has modified its progress report in that respect by providing that the city may make these repairs at the expense of the contractor and such expense shall be deducted from the retained money. When any part of the retained money is due to the contractor, only such balance as has not been expended by the municipality shall be considered to be due and payable. When the cost to the city of such repairs exceeds the amount of retained money, the balance shall be recoverable from the sureties.

Amendments to Progress Report

It therefore submits as its final report, all of its progress report down to the paragraph commencing: "For new construction involving grading," etc., and adds thereto the following:—

"For new construction involving grading, foundation and wearing surface, we would recommend that an amount equal to 5% of the aggregate cost of these items be retained.

"For surfacing on an old foundation, we would recommend retaining an amount equal to 8% of the cost of surfacing.

"In the case of a two-year guarantee, the whole of the retained money should be payable at its expiration and not before. In the case of a five-year guarantee, one-fourth of the retained moneys should be payable two years after the completion of the pavement and the balance in three equal instalments. The date when payments of retained moneys become due shall be governed by the clause previously recommended for pavements completed and accepted between November 1st and May 15th.

"If the contractor, having received notice from the engineer, fails to make and complete the ordered repairs within a reasonable time (not to exceed thirty days in any case), the city shall have the right to undertake and complete the ordered repairs at the expense of the contractor or his sureties."

*Final report of committee (Francis P. Smith, consulting engineer, New York, chairman) to the American Road Builders' Association.

†Published in *The Canadian Engineer*, June 12th, 1919.

SIX HUNDRED MANITOBA "GOOD ROADSTERS"

Assembled at Joint Roads and Municipal Associations' Banquet to Consider Province's Future Highways Policy and Welcome President S. L. Squire

WINNIPEG has been definitely chosen as the meeting place for the annual convention of the Canadian Good Roads Association to be held the second week in June, 1920, S. L. Squire, president of the association, announced last week at a joint banquet of the Manitoba Good Roads Association and the Union of Manitoba Municipalities. Over six hundred were present, representing every organized municipality in Manitoba.

The speakers of the evening were Sir James Aikins, Premier T. C. Norris, Mayor Charles F. Gray (Winnipeg), S. L. Squire and several others. Sir James Aikins said:—

"At this gathering are representatives of all organized Manitoba, who show their spirit by action as well as words in the upbuilding of our system of roads. Roads are now recognized as one of our greatest necessities."

Most Successful Year in History

S. R. Henderson, president of the Manitoba Good Roads Association, acted as chairman. "Ten years ago the Good Roads Association of Manitoba was inaugurated," he said, "and since the drafting of the Good Roads Act great strides have been made in the development of our roads. This has been the most successful year in our history."

Premier T. C. Norris declared that "the Good Roads Association and the Union of Municipalities are among our two most useful organizations. We have representative men here—men who carry on the good government of our municipalities. Co-ordination and co-operation is shown in this gathering. The question of good roads is one of the great problems of the day. The time has arrived when we must have a 365-day road in Manitoba. It will be some time yet before we reach such a standard, but we are gradually working there. The main trunk roads of the province should be dealt with first, and then the market roads should be built up. It is the intention of the province to have trunk roads extending across the province within a short time. Large sums will necessarily have to be expended and they must be spent well. In order to maintain our position as one of Canada's foremost provinces, we must have good roads. Good roads will have a good effect on community life. It will result in more of our young people staying on farms and will continue farming as our basic industry. The people of Winnipeg are taking a great interest in the building of roads, and if Winnipeg progresses other parts of the province will progress also."

No Particular Types Recommended

Mr. Squire outlined the work of the association during the past few years. Winnipeg was chosen for the next convention, he said, because of the great interest taken by that city and the west in the development of the roads. "We do not say what kind of roads should be built," said Mr. Squire, "as long as they are good roads. Every dollar spent on roads is an investment for the country. We are past the experimenting stage.

"There is no such a thing as a permanent road. The only thing that is permanent is the location. Roads must continually be repaired. Roads must be built to take care of the traffic to which they are subjected. Expensive roads should not be built where there is little traffic, and cheap roads should not be built where there is a great deal of traffic. We have come to the time when the government must take over the initiative and lay plans for the building of roads. It is purely the work of the government.

"In the past roads have followed colonization, but we have reached the period when colonization must follow the roads, just as immigration follows transportation. The building of roads will fill up the vacant lands of the west and result in greatly increased production. It will be a good investment and will mean the upbuilding of the country. The people will support the government which lays a good system of roads throughout the province."

FROST HEAVES STREET RAILWAY PAVING SLABS IN EDMONTON

By C. L. De Vall
General Contractor, Edmonton, Alta.

CONSIDERABLE inconvenience, and some delays to Edmonton's street railway system were caused recently by the early "freeze-up." The triangular-mesh-reinforced concrete pavement between the rails was heaved for several inches by the action of the frost—enough to interfere with the gear casings of the street car motors, causing suspension of traffic until the heaved slabs were removed.

TRACTOR DERRICK LOADING THE SLABS

This condition, arising quickly, required prompt action by the city's officials. The slabs varied in length from 6 to 16 ft., the larger ones weighing about 1½ tons each, presenting a rather awkward bundle to handle on account of their shape and weight.

The first operation was to remove the slabs from their location between the rails and skid them to the curb; this was done to open the lines quickly and to find temporary storage for the obstructions, although in a measure they were still more or less obstructions for vehicular traffic. Special equipment was necessary to remove these slabs

UNLOADING AND PILING SLABS AT POOL

from the curb advantageously. A tractor hoist and derrick was secured from a local contractor, and with its aid the slabs were loaded on flat cars, special hooks being used for grappling the slab.

This work was necessarily carried on in the early hours of the morning and was suspended when the cars started running. The time available each night proved too short to make sufficient headway with the work, so teams and sleighs were secured and the work carried on in daylight, this proving to be the more satisfactory method.

The problem of salvage and disposal was partially solved by deciding to line the children's swimming pool at the park with the slabs, which work will use up a large quantity of the slabs. For the unloading, a small stiff leg derrick was used to pile the slabs in accessible locations convenient for rehandling when the time arrives to line the pool.

INLAND WATERWAYS CONFERENCE

WITH the object of obtaining an inland waterway suitable for ocean-going freighters and extending from the Atlantic Ocean to the head of the great lakes, an organization to be known as the "Canadian Deep Waterways and Power Association" was perfected at a two-day conference held November 18th and 19th at Windsor, Ont.

This conference was the first of its kind in Canada, and was attended by representatives from many cities throughout the Dominion. The opening address was by E. L. Cousins, chief engineer and general manager, Toronto Harbor Commission, who took as his subject, "What the Canalization of the St. Lawrence Means to Great Lakes Points." He spoke of the work Toronto is doing in developing its waterfront and stated that approximately $25,000,000 will be spent in deepening the bay and reclaiming marshland.

Already $19,000,000 has been expended by the city, several millions by the government, and several millions remain to be spent. The returns on the money invested for the past year were still less than the expenditure, but Toronto is not disappointed, and believes that the large investment has been well made. On land which a few years ago was only marsh and shallow water, factories are now located which employ upwards of 6,000 men, and Toronto estimates that an additional population of 20,000—a small city in itself—has been attracted to the city by the harbor improvements and the new industrial sites built up from waste land to attract manufacturers.

Until Canada extends her export trade, said Mr. Cousins, she cannot expect to get a full dollar's worth for a Canadian dollar, and her citizens would have the experience which he had had in Detroit of having to pay five cents to get a Canadian dollar changed.

Toronto had undertaken great harbor improvements because Toronto is the logical importing and distributing point for the province of Ontario, and because she needed deep draft vessels to call at her port to carry her manufactures chiefly to distributing points. Last year the imports of Toronto were $17,000,000 in excess of Montreal.

A British investor who recently opened a factory in Toronto had said he would not have located there had he not anticipated that in a very near day he would be able to load his own boat with raw materials at Swansea, and unload it at his own wharf at the door of his Toronto factory.

Toronto now controls 99 per cent. of its water front, an advantage which no other city in America possesses. Out of the total appropriation Toronto has spent $2,000,000 in parks and boulevards, preserving a part of its water front for the recreation of its citizens. The newspapers supported the project strongly, and even the railroads gave it encouragement.

Dwelling upon the wonderful natural resources of Canada still untouched, Mr. Cousins mentioned a new discovery of what he believes to be the greatest iron deposits in the world, near James Bay.

Since Toronto improved her harbor, private capital has invested over $5,000,000 in land that was formerly marsh and water. A New York amusement firm had offered millions for amusement privileges on one point of the reclaimed land which has been kept for park purposes.

The possibilities of the development of ocean commerce on the Great Lakes were discussed by C. P. Craig, of Duluth, secretary of the Great Lakes-St. Lawrence Tidewater Association; Hon. Frank H. Keefer, Port Arthur, under secretary of state for Canada; and R. J. McLean, Detroit, ex-director of the Atlantic Deeper Waterways' Association.

Mr. Craig pointed out that the Canadian Northwest must have a market, which could only be obtained when greater transportation facilities are provided for ever-increasing production. He urged co-operation between Canada and the United States in furthering the project of canalizing the St. Lawrence. He asserted that the deepening of the St. Lawrence would reduce the cost of carrying a bushel of wheat from Duluth to Liverpool from 15 cents to 9 cents.

Mr. Keefer thought that the time is not far off when waters of the Long Sault will be harnessed to supply light and power for the homes and factories of Michigan cities. He said that the governments of the United States and Canada have been so interested in railways, and the railways themselves have been so selfish, that development of the Great Lakes as highways for deep-water vessels has been overlooked. The problem of carrying the increased production of the local northwest, which, he said, the railways had wholly failed to meet, can only be solved by deepening the St. Lawrence.

With more than a million horsepower available by proper development of the St. Lawrence, there is no reason why the whole of Ontario and a great portion of the State of New York should not be using "white coal," thereby releasing many million tons of coal for use in other sections of the two countries.

At the afternoon conference November 19th, Sir Adam Beck spoke on power development. He stated that by means of deepening the Welland Canal to from 25 to 30 ft., and deepening the St. Lawrence at one or two points, 90 per cent. of all ocean-going vessels in the world would be able to traverse the Great Lakes freely.

The power possibilities of the St. Lawrence were unexceeded anywhere. For four years the Hydro Power Commission had had a skilled staff of engineers and investigators, in constant research and investigation, collecting information and data regarding the possibilities of this development.

For the whole Great Lakes-St. Lawrence development scheme, not much more than $100,000,000 would be required. To carry the coal used in this territory 285,000 cars were required. By building one dam and deepening a waterway to 30 ft., half a million carloads of coal would be saved by the power developed for Ontario and New York.

Ninety per cent. of all ocean-going vessels could traverse a passageway 24 ft. deep.

The building of the Morrisburg dam would make possible the control of the levels of Lake Ontario, with a regulation of from two to four feet. It would also increase the depth of Montreal harbor from two to three feet, while now at certain times of the year vessels cannot dock at Montreal for lack of six additional inches of water.

Remedial works would also increase the levels of Lake Erie from two to three feet and 50,000 second feet would be gained without impairing the scenic beauty of Niagara Falls. On the American side 20,000 second feet would be gained.

W. M. German, K.C., the newly elected honorary president of the Canadian Deep Waterways and Power Association, said that before the St. Lawrence river could be navigable for ships 600 ft. long and requiring a 30-ft. draft, the expenditure would amount to about $200,000,000.

A resolution calling for the joint undertaking of the deepening of the Great Lakes waterways for ocean-going shipping by the governments of the United States and Canada was moved by O. E. Fleming, of Windsor, and seconded by Clarence R. May, of London, Ont. The resolution follows:—

"That this association is of the opinion that the work to be undertaken in the deepening of the natural watercourses for ocean-going shipping should be undertaken by the governments of the United States and Canada jointly, and that it should be operated as a joint undertaking, so far as the watercourses may be international, and that the water powers of the St. Lawrence should be developed to their fullest extent for the purpose of producing a revenue, such revenue to be used to provide a sinking fund for the retirement of the capital expenditure, payment of interest and maintenance and operation of the canal system and hydro-electric operation; and that in this way, in our opinion, the project should be made self-supporting."

Recovery of Valuable Constituents of Garbage

Summary of the Various Methods of Disposal of Municipal Wastes, Including Hog-Feeding, Incineration, Sorting, Reduction, Alcohol Production, Etc.—Paper Read Two Weeks Ago at Annual Convention of American Society for Municipal Improvements

By SAMUEL A. GREELEY
Consulting Engineer, Chicago, Ill.

THE subject-matter of this paper covers a large and important field of municipal activity. It is not within its scope to reach many of the details of the processes required for the economic recovery of valuable materials from municipal refuse; the paper deals very largely with general principles and the limitations attending their application.

The term "valuable" is, furthermore, difficult to use with any degree of certainty under present market conditions Only the most careful consideration of local conditions, with projects tempered by a measure of flexibility, can justify definite conclusions.

Particular attention is directed to the importance of local conditions in developing methods of garbage disposal. Apparently satisfactory garbage disposal is obtained in one place by incineration, in another by hog feeding, another by reduction, etc. Matters of administration, stage of city development, past experience and training in garbage disposal, location, climate, character of population, topography, soil and many other factors are pertinent.

Fundamental Considerations

Broadly speaking, a method of final disposal of municipal refuse should serve three functions as follows: (a) It should render satisfactory service to householders; (b) it should be measurably clean and sanitary; (c) it should be reasonably economical.

In accomplishing these three ends, there are four parts, or phases, of the problem to be developed, as follows: (1) The house treatment; (2) the collection; (3) the transportation; (4) the final disposal.

The problem of garbage disposal is the proper development and adjustment of these parts of the problem to local conditions. The house treatment more directly affects the people; the collection is generally the more costly part of the work; transportation other than in collection wagons is needed only in the larger communities; while final disposal involves more engineering work and in general stimulates more discussion than the others. In the author's opinion each of the four phases is equally important, and a limitation of what follows primarily to disposal is not intended to eliminate or discard the influence of "house treatment" and "collection" upon the disposal.

Two other fundamental considerations are important, viz.: (a) The so-called relative values in sanitation; and (b) the fact that a successful handling of the refuse problem revolves primarily about operation.

By relative values is meant such items as, for instance, the stage of other municipal improvements possibly more directly affecting the public health, as well as the question of the proper cost of measures for eliminating odors not constituting a general nuisance. It is also obvious that "operation" looms large in refuse disposal work and must be given first consideration during the development of new works.

Valuable Constituents

Refuse is the term for the solid waste resulting from community activities as distinguished from sewage. Refuse is made up of garbage, ashes, rubbish, manure and many other materials. The valuable constituents contained in them are as many as the varied activities of the community These constituents may, however, be roughly classified by the disposal methods used to recover them, thus:—

1. Dumping, or land fill, makes the fullest use of the inert constituents of refuse not otherwise generally useful. Sometimes valuable land can thus be made.

2. Burial, or ploughing into the soil, makes possible the recovery of those constituents of refuse which are valuable for fertilizing the soil. Manure is quite generally disposed of in this way and some cities have developed its collection and transportation to farming districts very advantageously to the public comfort and the municipal pocket book. At Columbus, Ohio, a gross revenue of about $4,000 per annum is derived from the sale of manure. Street sweepings are also used in this way; sometimes, for instance, to cover dumps of mixed refuse for park purposes.

3. Mixed refuse can be burned at high temperature, producing steam suitable for power development, thus recovering or using the carbon and hydrogen contained in the refuse. With the increased demand for power, the higher price of coal and oil, and the gradual reduction in available close-by dumping areas, the value of refuse for steam production is increasing.

4. Garbage contains grease and tankage, both valuable constituents which are being economically recovered on a large scale by the reduction process.

5. From rubbish many marketable materials can be recovered, such as paper, rags, leather, old metals and the like. The process is commonly termed "rubbish sorting."

6. An old and universal method of recovering the valuable food constituents from garbage, is by feeding to hogs. This is one of the most interesting and useful methods of garbage disposal which has recently been given much prominence by war shortage of food.

7. There are many other processes for the recovery of valuable constituents from garbage which have been more recently studied, such as the production of alcohol and the preparation of a stock and chicken food.

Hog Feeding

For garbage alone, feeding to hogs is a method of disposal which undoubtedly has a wide field. By this method the food constituents of garbage are recovered in part. Some tests during an investigation of the refuse disposal problem made by the writer in Louisville, Ky., showed that 32.4 pounds of city garbage were required to add one pound to the weight of the hogs. The tests lasted seven weeks and covered observations on the feeding and growth of 25 to 40 hogs. The garbage was taken from several collection districts, but contained a somewhat smaller amount of other refuse materials than does much city garbage. With pork on the hoof at 15 cents a pound, the garbage would have a gross value of $9.26 per ton. It was actually sold by the city at that time (September, 1918), at $3 to $3.50 per ton for feeding to hogs.

At Worcester, Mass., where the separation of garbage is very good, it takes 37.5 pounds of garbage per pound gained by the hogs.

Hotel garbage has a higher food value. Mr. Gaumnitz, who feeds such hotel garbage in St. Louis, states that it takes only 25 pounds of such garbage to make one pound of gain on a hog; and this data is confirmed by tests at the Iowa Agricultural Experiment Station. At 15 cts. per pound of pork, hotel garbage should thus have a gross value for feeding purposes of $12 per ton.

From the gross indicated value of garbage for hog feeding, it is, of course, necessary to deduct plant operation, risk overhead, fixed charges, etc. These vary with the location of the hog farm, the value of the land, the climate, the length of the contract and the care with which the operation of the farm is conducted. In 1916, in connection with a study of

garbage disposal in Worcester, Mass., the writer estimated the total annual cost at $2.30 per ton, which was considered rather liberal at that time, but was predicted on an ample plant and good operation. As a matter of fact, contractors seem willing to pay not much over $1 per ton for city garbage, and in some cases less, some contract prices being as follows:—

Town.	Year.	Price paid by contractor to city per ton of delivered garbage.
Minneapolis, Minn.	1918	$1.26
Grand Rapids, Mich.	1917	0.45
Portland, Ore.	1918	3.90
Newark, N.J.	1919	1.20*
St. Paul, Minn.	1917	0.80
South Bend, Ind.		....
Anderson, Ind.	1917	1.00

*Figured at 8 times the pound price of live pork in Chicago.

The operation of hog farms is not an easy matter and varies considerably in different places, which may possibly explain the abandonment of hog feeding as a method of disposal in some cities. Of first importance is a superintendent who knows the feeding and care of hogs. But sanitary considerations are likewise important and must supplement the experience of the hog feeder. The more important items are:—

(a) Methods of feeding, (b) area required, (c) pens and runways, (d) vaccination, (e) disposal of unconsumed garbage, and (f) suppression of rats and flies.

The design will depend somewhat upon the location of the hog farm. For instance, in a report on hog feeding of garbage at Rockford, Ill., the writer recommended that "no garbage be fed to hogs in buildings closer than 300 ft. from a traveled roadway, and that garbage fed out of doors on platforms should be at least 600 ft. away."

Of paramount importance, however ,are matters of house treatment, frequency and adequacy of collection, and other items affecting the public comfort and the quality of the garbage.

Incineration

The carbon contained in refuse is a valuable constituent. The carbon content of garbage is low, generally less than 5%, and is not sufficient to warrant economical recovery. However, the carbon content of ashes and rubbish is higher, and so-called "mixed refuse" (garbage, ashes, and rubbish as collected from houses) contains as much as 20% of carbon. This gives it a value of about one-fourth that of coal (80% carbon), and as many municipalities are now paying upwards of $5 per ton for coal for pumping stations and lighting plants, the indicated gross value of a ton of mixed refuse is $1.25. Assuming an average evaporation of one pound of steam from and at 212 deg. F. per pound of refuse, this is equivalent to 6¼ cts. cost per 100 lbs. of steam, as compared with 4 cts. per 100 lbs. of steam used in the Milwaukee incineration tests in 1910.

A plant to burn mixed refuse should be especially designed for that purpose. The details of design cannot be taken up in this paper, but there are a number of plants which have been giving good service for periods up to 12 years as at Westmount, Savannah, Altanta, Milwaukee, West New Brighton and elsewhere. A record of power production at the Milwaukee refuse incinerator is shown in Table 2, and a record of operation of the refuse incinerator at Westmount, P.Q., in Table 1.

In projects for mixed refuse incineration, the effect (of collecting the refuse mixed) on the house treatment and cost of collection are important factors.

Rubbish Sorting

Rubbish contains much material which can be sorted out and sold, such as paper, rags, metals, rubber, shoes, and the like. During the war, the government urged that this should be done as a conservation measure, and there appears to be no reason why the practice is not good.

The gross value of rubbish varies with the market over a wide range. From 35% to 50% of the rubbish by weight can usually be recovered under normal city conditions. These materials bring in a gross revenue of about $2 per ton of rubbish on pre-war prices. The figures from the Columbus municipal rubbish sorting plant are given in Table 3. The selling price of rubbish materials in the Chicago market from quotations dated November 7th, 1919, are as follows:—

Metals—

A rubbish sorting plant comprises a receiving room and a wide belt conveyor travelling slowly up between two platforms on which the sorters stand. Along the outside of each platform are bins for storing the sorted materials. Below the bins are baling presses and other apparatus used to prepare the materials for shipment. An incinerator, usually with a boiler, is required to burn the unsorted rubbish. Such plants are in operation at Buffalo, Rochester, Pittsburgh, Columbus and elsewhere; and in many places rubbish materials are sorted on the dump and sold. The revenue from the sale of the sorted materials does not usually much more than pay for the cost of operation.

Reduction of Garbage

Reduction of garbage is a chemical and mechanical process whereby the garbage is separated into four parts, viz.: Volatile matter driven off as gas; water; grease; and dry material which is somewhat stable, mostly fibrous, and of vegetable and animal origin, and called "tankage." The grease and tankage have market values.

TABLE 4—VALUE OF PRODUCTS FROM GARBAGE

Market price of grease, per pound.

1919	.....	10.00	.....

*To August 1st. **Balance of year.

The amount of these materials which can be recovered depends upon the character of the garbage and the process used for recovery; 2½% of grease and 11% of tankage by weight of raw garbage may be recovered. The gross value of these constituents depends upon the market price, which varies greatly, as shown in Table 4. The present market price of grease is about 6 cts., and of tankage about $10 per ton, which would indicate a gross value of garbage for the reduction process of $4.10 per ton. During the war these prices were doubled.

Many processes have been devised for reducing garbage, cost of which fall into one of three groups designated as follows:—Drying method, cooking method, and Cobwell process.

The Cobwell process is the most recent and may be described as the "dehydration, or drying, of the garbage by cooking at low temperature while immersed in a solvent, the extraction of grease from the dried garbage by the same solvent, the recovery of the solvent for further use, and the production of grease and dry tankage for the market." Almost all of the action takes place in closed reducers and the connections. At New Bedford, Mass., the recovery by the process is stated to be 4% of grease and 15% of tankage, and at Los Angeles, Cal., 15.5% of grease and 3.1% of tankage.

1913	20,711	2.72	10.5
1914	21,629	2.73	9.7
1915	22,909	2.21	10.0
1916	21,862	3.08	10.3
1917	17,127	2.26	10.21
1918	15,630	2.16	10.26

*At Columbus operation was begun in July, 1910, and there was no percolation until January, 1912.

In the drying method, the garbage is first dried and then degreased in naphtha percolators. The grease recovery is comparatively low and the tankage recovery somewhat higher than in other processes. At the Chicago reduction plant, which uses the drying method, the percentage of grease recovered is 2.0, and of tankage 22.7, for the year 1918.

The cooking method comprises a first cooking of the garbage with live steam under pressure, then pressing out the free water and grease, then drying the pressed material, and finally recovering additional grease by percolation with a solvent. This process is used at Cleveland, Columbus and elsewhere. The percentage of grease and tankage recovered is shown in Table 5. Garbage reduction plants are usually located at some distance from built-up districts, which requires a transportation of the garbage. This and other local factors, such as size of city, should be considered in connection with this method of disposal.

There are, in addition to the more generally used methods mentioned above, several comparatively new methods not yet tried out on a very large scale. The Union Poultry Food Co.,

of Los Angeles, have a process which consists in placing the garbage, as collected, in a direct heat steam dryer. The dried product, which amounts to about 18% by weight of the garbage, is sold for poultry food, bringing as high as $40 per ton. This would indicate a gross value of the garbage of $7.20 per ton. The process has been considered at Kansas City, Mo.

A process for the production of alcohol from garbage, under patents held by Dr. S. J. Morgan, has been tested (1916) on an experimental basis at Columbus, Ohio. These tests showed a possible yield of 4.8 gals. of alcohol per ton of garbage, which, at 40 cts. per gallon, indicates a gross value of $1.92 per ton of garbage. It appeared from the tests that the recovery of grease and tankage was not materially affected by the alcohol recovery process.

There are, of course, other processes, such as that of Dr. Marsh, recently considered at St. Louis, which the inventor guarantees will yield "at ordinary market prices" not less than $3.60 per ton of garbage; the "Nufuel" or "Oakoal" process for making fuel briquettes; and others.

Summary

The writer does not feel justified in offering any conclusions in this paper except that garbage disposal should be considered with a view, where possible, to an economic recovery of valuable constituents. The lure of profit, however, should not overshadow the development of operation for the convenience and comfort of the householder and for the economy of collection.

It is a mistake to arouse public opinion on the matter of disposal where other parts of the problem are of equal importance and sometimes more costly. Nevertheless, economy of operation, elimination of waste, the salvage of useful and essential materials, are matters of vital importance in the present development of society, and the skill and efficiency with which they are done will reflect the general progress of the community.

This means that the economic value of valuable constituents of garbage and other refuse materials must be considered with the house treatment and collection, first cost of plant, overhead and fixed charges, and costs of operation. When and where the problem is approached in this broad, sound way, the writer believes that methods of disposal involving the recovery of valuable constituents will endure and will permit of operation without the interruptions and changes of method which now occasionally occur.

The Mechanical Engineering Department of the University of Manitoba, Winnipeg, Man., requests all firms manufacturing mechanical machinery and apparatus of all kinds to place the department on their mailing lists for catalogues, bulletins, etc.

Boynton & Williams, dealers in contractors' supplies, have moved to new and larger offices and warerooms at 42 Lombard St., Toronto. George P. Beswick, secretary of the Purchasing Agents' Association, and for twenty years with the Polson Iron Works, Toronto, has been appointed office manager and purchasing agent of the Boynton & Williams organization. At the new warehouse a large stock of pipe, valves and fittings is being carried. The firm also acts as representatives for a number of American manufacturers, and deals in new and used machinery.

In a circular letter sent to water companies and departments by the American Water Works Association, the formation of the American Committee on Electrolysis is announced, with representatives from water, electrical and railway engineers' and gas associations, etc., the purpose of this committee being to gather and classify information regarding electrolysis and to study and report on methods of construction and means of mitigation. The committee will co-operate with the Bureau of Standards in carrying out experiments and investigations and it is proposed that Prof. Lewis Allen Hazeltine, of Stevens Institute, should serve as a technical expert on the consulting board, on behalf of the interests of the water companies and departments. Subscriptions towards a fund of $3 000 to finance this work are now being solicited.

NO ROOM FOR TRADE UNIONISM IN ENGINEERING PROFESSION, SAY DIRECTORS OF AMERICAN ASSOCIATION OF ENGINEERS

FOLLOWING is a statement that has been issued by the executive committee of the American Association of Engineers, setting forth the position of that association in regard to trade unionism in the engineering profession:—

Reason for Statement.—In the present state of industrial unrest, the Board of Directors of the American Association of Engineers considers it desirable to make a statement defining the position of the association.

Responsibility.—The American Association of Engineers is an incorporated organization responsible for its acts.

Economic Position of the Engineer.—The engineer is the medium through which both capital and labor are used in production and in industrial development. The aim of the profession is to advance civilization and render the highest service to society. Except when their acts further this aim, it is an advocate of neither capital nor labor.

Increased Production.—Production should be increased—not limited. The profession cannot support strikes or lockouts or any other methods that may benefit any class at the expense of the nation as a whole. They are unsound and must inevitably lead to economic disaster. The law of supply and demand for men or material must ultimately prevail. Attempts may be made to limit the supply of either, but looking toward the upbuilding of civilization, we believe rather in increasing the demand through the promotion of legitimate enterprises.

Reward According to Merit.—Rewards should be according to ability, initiative and constructive effort. Men are not equal in these respects. Each man should be encouraged to do his utmost and be given compensation according to ability and will to increase production and to achieve large results.

Methods.—The engineer, as an educated professional man, believes in basing his claims for proper and just reward for his services upon the justice of the facts presented, upon enlightenment of public opinion, upon loyalty between employer and employee, and upon the underlying fundamental desire of the great majority to do what is fair and right when the merits of the case in question are clearly presented and demonstrated. We believe in organized representation for the correction of wrong, the advancement of the profession and service to the public, but are opposed to methods inconsistent with the dignity of the profession and which would lessen public confidence.

Conclusion.—The American Association of Engineers, through its Board of Directors, who have signed this statement, recognizing the many fundamental differences between the principles and objectives of the trade union and of an organization of professional men, expresses the opinion that an engineer cannot subscribe to the tenets of both.

Signed by Dr. F. H. Newell, head of department of civil engineering, University of Illinois; W. W. DeBerard, western editor, Engineering News-Record, Chicago; T. A. Evans, assistant engineer, Jacobson & Schraeder, Chicago; R. Burnham, consulting engineer, Chicago; W. W. K. Sparrow, chief engineer C. M. & St. P. Ry., Chicago; Harold Almert, consulting engineer, Chicago; J. N. Hatch, consulting engineer, Chicago; F. K. Bennett, principal assistant engineer, M. & St. L. Ry., Minneapolis; H. W. Clausen, general office manager, C. D. Osborne Co., Chicago; C. A. Soans, patent attorney, Chicago; W. D. Wilcox, past president, American Association of Engineers; L. K. Sherman, U. S. Housing Corporation, Washington, D.C.; Isham Randolph, consulting engineer, Chicago; Alexander Potter, civil engineer, New York; E. F. Collins, valuation engineer, St. L.S.F. Ry., St. Louis; C. H. Crawford, manager, Baldwin Locomotive Works, Philadelphia; John Ericson, consulting engineer, Department of Public Works, Chicago; and C. E. Drayer, secretary, American Association of Engineers.

(NOTE.—Since the above statement was received, we have been advised by C. E. Drayer, secretary of the American Association of Engineers, that all of the other directors of the association have added their signatures to the statement, making it unanimous.—EDITOR.)

AWARD HIGHWAY CONTRACTS EARLY!

IN a letter addressed to the heads of the State Highway Departments, Thomas H. MacDonald, chief of the Bureau of Public Roads, United States Department of Agriculture, urges the state departments to place under contract during December and January as great a mileage of roads as possible.

Mr. MacDonald estimates the amount of money available for road work in the United States during 1920 to be $633,000,000, or more than four times as much as has been expended during any previous year for like purposes. He calls attention to the lack of open top cars for transporting road materials, and says that this deficiency must be made good by using these cars more efficiently and by awarding contracts sufficiently early to permit contractors to obtain their materials during the season when the open top cars are not in the greatest demand.

Last spring the number of open top cars that were idle in the United States was estimated at over 250 000, but as the season advanced and road contracts were actually under way, acute car shortage manifested itself generally throughout the country.

Should the movement of coal demand the cars, or should there be any railroad labor trouble, highway work would be sadly interfered with in case the contracts are awarded too late, inasmuch as road materials are not perishable and are among the last things that would be moved on the rails.

What Mr. MacDonald says in regard to conditions in the United States applies with equal or greater force to Canada. The placing of materials in storage piles involves some expense, but this cost is small in comparison to the loss occasioned by the lack of materials when the contractor's organization is waiting. Contracts which are not awarded during the winter months may have little opportunity of being supplied with materials which require railway transportation.

Another good feature of the early award of highway contracts is that the contractors are encouraged to place their orders early, and material producers are given an opportunity to operate their plants during all seasonable weather. Not only does this help the car shortage, but it generally results in lower prices.

THE ASPHALT ASSOCIATION

THOSE who are interested in the movement for better roads and streets in Canada will note with pleasure the strong engineering staff which is being built up by the Asphalt Association. As is now undoubtedly well known by the readers of our paper, this association was formed a few months ago by a number of competing asphalt producers for the purpose of ensuring not only the widest possible use of their product, but also the most efficient use. In forming an association of this kind for general promotion and research work, the asphalt producers are merely getting into line with the service policy that is now rapidly being adopted by all industries that are conducted upon the best business principles.

Highway engineering in Canada will undoubtedly benefit by the formation of the Asphalt Association. The service which its engineers and laboratories can render will not be any the less appreciated for the fact that these engineers are at the same time promoting the sale and use of asphalt. All service has a *raison d'être*, and good service, whether in engineering or other fields, is always entitled to recognition and reward. The service which the Asphalt Association will render will undoubtedly be met with a marked increase in the use of that material.

The officers of the Asphalt Association indicate its high standing in point of responsibility for data published, and also its independence from a competitive standpoint. They are as follows:—

President, J. R. Draney, of the United States Asphalt Refining Co.; vice-president, W. W. McFarland, of the Warner-Quinlan Asphalt Co.; treasurer, N. G. M. Lykx, of the Freeport Mexican Fuel Oil Co.; secretary, J. E. Pennybacker, formerly secretary of the U. S. Highways Council and formerly of the U. S. Bureau of Public Roads; chief of research department, Prevost Hubbard, former chief of tests and research of the U. S. Office of Public Roads.

The intimate relation which both Mr. Pennybacker and Mr. Hubbard have had with the good roads movement on this continent for the past fifteen or twenty years is too well known for them to need any introduction to Canadian engineers. Bruce Aldrich, the engineer who will be in charge of the affairs of the association in Canada, is not so well known in this country, but among engineers in the United States, particularly in the south, his experience and ability have long been recognized. His work in connection with street improvement and maintenance in Baltimore has well trained him for his new duties. Mr. Aldrich will not endeavor alone to solve the many paving and other problems which may be placed before him, but will merely serve to a certain extent as a link between the Canadian territory and the authoritative laboratory and engineering facilities which the Asphalt Association is rapidly establishing.

AMERICAN ASSOCIATION OF ENGINEERS

REMARKABLY rapid has been the growth of the American Association of Engineers. Founded in 1915, this association had a membership of approximately 250 at the beginning of 1916, 750 at the beginning of 1917, 1,500 at the beginning of 1918 and 2,500 at the beginning of this year. The membership of the association last Thursday was 8,866, and the officers have arranged a membership drive, to be carried out the first two weeks of December, which will undoubtedly boost the number to five figures.

Compared with the growth of the four main engineering societies in the United States, the American Association of Engineers has had a record-breaking career. It now has about

1,500 more members than has the American Institute of Mining and Metallurgical Engineers, and it has practically the same number as the American Society of Civil Engineers; moreover, it is only about 1,000 short of equalling the membership of either the American Institute of Electrical Engineers or the American Society of Mechanical Engineers. All four of these societies were, of course, founded many years ago, and have a tried and established membership which is immune from any fluctuations such as may or may not occur in the membership of the American Association before that organization is as old as is any of the other four societies.

During the past 10½ months the American Association of Engineers has grown almost as much as has the average membership of the other four societies during the last 17 or 18 years. The executive committee of the association express confidence that their organization will be the largest engineering society in the United States before the end of this year.

PERSONALS

PAUL EMILE MERCIER, consulting engineer to the Administrative Commission of the city of Montreal, who was recently appointed as a professor on the staff of L'Ecole Polytechnique, Montreal, and who will hereafter devote a considerable portion of his time to educational work, was born March 15th, 1877, at St. Hyacinthe, P.Q. He was educated at St. Mary's College, Montreal, and received his technical training at L'Ecole Polytechnique. He became chainman on the Montreal Park & Island Railway in 1895. Entering the service of the C.P.R. in 1896, as a rodman on the Quebec division, he became a leveller in 1897. In 1898, he joined the staff of the Public Works Department of Canada, as an assistant engineer, and from 1899 to 1904 was a district engineer in that department. In 1905 his services were requested by the National Transcontinental Railway, and for the following two years he was engineer in charge of that project. In 1908 Mr. Mercier engaged in private practice in Montreal, under the firm name of Baulne & Mercier, which connection was retained until 1914, when he was appointed deputy chief engineer of the city of Montreal. When George Janin, chief engineer of the city, was given leave of absence to go overseas in December, 1914, Mr. Mercier became acting chief engineer, and upon Mr. Janin's death in 1915, Mr. Mercier was appointed chief engineer. In May, 1918, he became the city's Director of Public Works, from which position he retired in November, 1918, to act as consulting engineer to the newly-appointed Administrative Commission. Mr. Mercier is a member of the Engineering Institute of Canada, the American Railway Engineering Association, the American Society of Civil Engineers and the Society of Civil Engineers of France.

A. P. MILLER, of Glenmiller, Ont., has been appointed assistant engineer on the Trent Canal staff, Department of Railways and Canals.

B. H. PRACK, industrial architect and engineer, has moved his Toronto office from the Lumsden Building to the Otis-Fenson Building, where he is now occupying the entire top floor.

PROFS. NORMAN BOWEN and CECIL GREENLAND, of the Faculty of Science, Queen's University, have resigned. The former is going to Washington, D.C., while Prof. Greenland is leaving for South America.

W. G. H. CAM has been appointed power engineer for the Canada Cement Co., Ltd., Montreal. He was formerly engaged in the design and construction of lighting and power systems in Montreal and vicinity.

ARTHUR SANDE, consulting engineer, has established an office in the Lister Building, Hamilton, Ont. Mr. Sande will specialize in buildings and equipments for industrial plants, hydro-electric developments, pulp and paper mills, steel mills, foundries, etc.

LT.-COL. CHAS. G. DU CANE, O.B.E., who was engaged all last summer on work connected with the Madras docks and harbors, and who has just sailed for London, Eng., to complete his report, will return to Vancouver in January to resume business with his former firm, Du Cane, Dutcher & Co., consulting engineers, who have in hand a number of new and important projects.

GUY MORTON, formerly Alberta manager for the Canadian Westinghouse Co., Ltd., has organized "Electrical Engineers, Ltd." at Calgary, Alta. Mr. Morton's new firm will deal in electrical and mechanical engineering equipment. He is a graduate of the University of Toronto in mechanical and electrical engineering, class of 1909, and served overseas as a lieutenant, returning to Canada only four weeks ago.

J. A. OWENS, who graduated in civil engineering at the University of Toronto, class of 1914, has joined the staff of J. B. Nicholson, Ltd., of Toronto and Hamilton, as resident engineer on reinforced concrete construction in Toronto. Mr. Owens was formerly with Wheelock & Christie, consulting engineers and surveyors of Orangeville, Ont., and for the past few months has been in the employ of James, Loudon & Hertzberg, Ltd., consulting engineers, Toronto.

PROF. L. W. GILL, of Queen's University, Kingston, Ont., has been appointed Director of Technical Education, Department of Labor, Ottawa. This directorate is a new office the creation of which was made necessary by the action of parliament in voting $10,000,000 to be spent on the encouragement of technical education throughout Canada. The money for the most part is to be spent by the provinces on the basis of agreements to be reached with the provincial governments, in much the same manner as federal votes in aid of agriculture have been distributed. Prof. Gill served with the Canadian forces overseas, in command of the 46th Battery. He has been head of the electrical engineering department of Queen's University for the past fifteen years.

ONTARIO PROVINCIAL DIVISION, E. I. C.

TWENTY-SIX engineers, representing the various branches of the Engineering Institute of Canada throughout Ontario, met last Friday afternoon and evening at the Engineers' Club, Toronto, as delegates to the first formal conference of the institute's Ontario Provincial Division. J. B. Challies, of Ottawa, chairman of the division, presided.

The most important decision reached was that a joint committee of twelve men be formed to consider legislation for Ontario, the division to name two of the twelve and two to be named by the Ontario branches of each of the following five organizations: The Canadian Mining Institute, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the Canadian Institute of Chemistry and the Ontario Association of Architects.

The other matters discussed were solely internal affairs of the institute, chief of which was a recommendation to the council of the institute that Ontario be divided into three districts instead of two, so as to give Western Ontario larger representation on the council.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

ADDITIONAL TENDERS PENDING

Not Including Those Reported in This Issue

Further information may be had from the issues of *The Canadian Engineer*, to which reference is made.

PLACE OF WORK	TENDERS CLOSE	ISSUE OF	PAGE

BRIDGES, ROADS AND STREETS

Barton Tp., Ont.—Township council will reconstruct two roads. Clerk, A. G. E. Bryant, Mount Hamilton, Ont.

Cayuga, Ont.—The ratepayers passed a by-law to raise $10,000 for good roads. Clerk, R. S. Coulter.

Chippawa, Ont.—Time for receipt of tenders by the Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, for Chippawa Highway Bridge has been extended to 12 o'clock noon, December 6th, 1919.

Lindsay, Ont.—Scott's Creek bridge, on the boundary of Victoria and Ontario counties, will not be built until next year.

Cleveland, Que.—Tenders for gravelling parts of the Spooner Pond and Craig's Rd. will be received up to December 1st, 1919. Plans and specifications may be obtained on application at the secretary's office, Richmond, Que.

Cornwallis, Man.—On December 16th electors will vote on by-law to borrow $100,000 on debentures for the construction and improvement of roads. Secretary-treasurer, D. W. Shaw, Brandon, Man.

Hamilton, Ont.—Plans for a new cemetery include the macadamizing of 1,700 yds. of roadway, at a cost of $11,000; the filling in of 2,000 feet of roadway and the erection of a concrete bridge, at a cost of $35,000, or a total of $46,000. Chairman Cemetery Board, Mr. Peebles.

Hampstead, N.B.—Contract for the construction of the Little River (Mouth) bridge has been awarded to the Concrete builders, Ltd., of Fredericton. The bridge is to have a reinforced concrete arch span with concrete abutments. The contract price is about $37,000.

Kitchener, Ont.—City council may extend Homewood Ave.

St. Andrew's, Man.—By-law will be submitted to electors on December 16th providing for the construction of a system of roads and improvements. Estimated cost, $424,728. Clerk, J. D. Forster, Clandeboye, Man.

St. John, N.B.—City council adopted recommendations that plans and specifications be prepared for paving with bituminous concrete the whole of Douglas Ave., City Rd., Brussels St. and Marsh Rd. City engineer, G. N. Hatfield.

St. John, N.B.—City council let contract to Morrison and Newlands for 50,000 granite blocks at $87.50 per thousand.

St. Thomas, Ont.—City council intends to construct an asphalt pavement on Talbot St., from Mary St. to Balaclava St., with concrete curb and gutter on each side of the street. The estimated cost of the work is $98,327. City clerk, W. B. Doherty.

St. Thomas, Ont.—London and Port Stanley Railway Commission will commence work immediately on the erection of a bridge over Kettle Creek. Vice-chairman, Philip Pocock, London, Ont.

Toronto, Ont.—Works Commissioner Harris has recommended the construction of a bitulithic pavement on Amroth Ave. at a cost of $18,093.

Toronto, Ont.—City council intends to grade Bellefair Ave. at cost of $3,400, and extend Redpath Ave. at cost of $9,850. City clerk, W. A. Littlejohn.

Toronto, Ont.—Board of Control referred to the Property Committee a proposal to cut a street through the jail property across the corner from Broadview Ave. to Gerrard St.

Toronto, Ont.—R. C. Harris, Commissioner of Works, recommended opening of lane between St. George and Huron Sts., southerly from Dupont St. Estimated cost, $2,300. Works committee recommended adoption of this report.

Toronto, Ont.—City council intends to construct asphalt pavements on Gerrard St. and Swanwick Ave. at cost of $2,191.61; concrete curbings on Gerrard and Keele Sts., cost, $1,530; extend Norway Ave. at cost of $40,000, and grade Hillingdon Ave. at cost of $9,605.

Toronto, Ont.—Board of Control let contract for supply and delivery of material for canopies over sidewalks under subways at King St., Queen St., and Lansdowne Ave., to the A. B. Ormsby Co., Ltd., Toronto, at $3,441.60 total, material to be keystone copper bearing steel sheets.

Toronto, Ont.—Works Commissioner Harris recommended the construction of the following pavements: Devon Rd., from Cassels St. to Gerrard St., asphalt, $10,418; Evelyn Ave., from Glendonwynne to Evelyn Cres., bitulithic, $6,621; Willard Ave., from Bloor to Colbeck, bitulithic, $26,295; Colbeck St., from Windermere to Jane, bitulithic, $25,571.

Toronto, Ont.—Works Committee recommended the construction of the following: An asphalt pavement on Lyall Ave. at a cost of $32,749; the resurfacing with asphalt of both sides of Spadina Ave., between King and Adelaide Sts., at a cost of $8,295; an asphalt pavement on Teraulay St., Dundas to College St., at a cost of $42,218; a permanent pavement on Amroth Ave. at a cost of $18,093.

Winnipeg, Man.—Applications from eight provincial municipalities for roadwork under the Good Roads Act have been approved to the amount of more than $1,000,000.

Winnipeg, Man.—The Parks Board will call a meeting of representatives from the municipalities of Charleswood, Tuxedo, Assiniboia, Macdonald and Rosser to discuss the erection of a new bridge at Assiniboine Park.

Winnipeg, Man.—Hon. George A. Grierson, Provincial Minister of Public Works, announced that survey work for the construction of a 40-mile summer road to the Rice Lake gold fields would start early in January. The estimated cost

of a bridge in this connection over the Winnipeg river is $350,000, and the cost of the road is estimated at approximately $80,000.

York County, Ont.—Work on rebuilding the Baldwin bridge may start soon. Estimated cost, $22,019.

WATER, SEWAGE AND REFUSE

Beaverton, Ont.—Report submitted by the E. A. James Co., Ltd., Toronto, on proposed waterworks system, estimated to cost $85,000, which includes intake into Lake Simcoe, filtration plant, pumps, elevated tower and mains. Council decided to take vote of people in February, 1920.

Burlington, Ont.—Tender of S. Oakes for house sewer connections on St. Paul, Green and Caroline Sts. were accepted by town council.

Forest, Ont.—Report submitted by the E. A. James Co., Ltd., Toronto, on waterworks system, estimated to cost $62,000, which includes mains, pumps, water tower and deep well. Council decided to submit same to vote of people, January, 1920.

Guelph, Ont.—City council passed a by-law providing for the construction of sewers on York Rd., Havelock, Toronto, Inkerman, Duke, Harris and Alice, Ferguson and Metcalf Sts. City engineer, F. McArthur.

Hamilton, Ont.—City engineer E. R. Gray presented to the board of control an extensive overflow sewer scheme, the central and western portions of which are estimated to cost in the neighborhood of $1,500,000.

Hamilton, Ont.—City council intends to construct pipe sewers on Paradise Road and Roxborough Ave., at a cost of $3,275.28. Also pipe sewer on Burlington St., cost, $41,335.51. City clerk, S. H. Kent.

North Bay, Ont.—Tenders will be called for improving, altering and extending sewers in Worthington and Sherbrooke Sts. involving 6,000 ft. 30 in. reinforced concrete pipe. Cost, $25,640. Town engineer, H. J. McAuslan.

Peterboro', Ont.—City council intends to construct a sewer on Dublin St. City engineer, R. H. Parsons.

Sudbury, Ont.—Plans have been prepared and estimates are being obtained for the proposed completion of the west end sewer system. Mayor, P. Morrison.

Toronto, Ont.—Works Commissioner R. C. Harris will prepare a report on a water service for the eastern district of York.

Toronto, Ont.—Construction of relief sewer from south end of Campbell Ave., westerly to Symington, is considered necessary by Works Commissioner R. C. Harris.

Toronto, Ont.—Works Commissioner Harris reported to Board of Control that it will be necessary to replace four of the electrically driven pumps which supply the city with water before next summer. The cost is placed at $75,000. Tenders will be called.

Welland, Ont.—City council will have water main laid to River Road. City engineer, Chas. L. Coulson.

Welland, Ont.—City council let contract for the construction of the Smith Street sewer to A. D. Brown at a cost of $3,083.33. Other tenders were received as follows: Louis Sacco, $4,438.98; Somerville and Dillworth, $3,259.99. The city engineer's estimate of the job was $2,590.

Windsor, Ont.—Plans of the Essex Border Utilities Commission to consolidate the waterworks systems of Windsor and Walkerville to supply the five border municipalities with filtered water at cost will be submitted to the ratepayers in January. The project will involve $2,000,000.

Winnipeg, Man.—Tenders, addressed to the chairman of the Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m., Monday, December 15th, 1919, for the supply of hydrants and valves for the Domestic Waterworks System. Specifications may be obtained at the office of the city engineer, 223 James Ave.

LIGHT, HEAT AND POWER

Kingston, Ont.—The A. F. A. Coyne Co. has been granted a franchise for the supply of natural gas to Athabaska. The agreement calls for the placing of the pipe lines by May 1st next, and the completion of the whole system by October 1st.

North Battleford, Sask.—Tenders addressed to Robert Farquharson, city clerk, and marked, "Tender for Power Plant Equipment," will be received up to 5 p.m. on Saturday, December 6th, 1919. Plans and specifications may be obtained on application to M. D. Cadwell, Superintendent of Utilities, City Hall, North Battleford, Sask.

Winnipeg, Man.—Time for receipt of tenders for manufacture, delivery and erection in city's power-house at Point du Bois of two units of horizontal shaft turbines for direct connection to alternating current generators and governors for controlling same has been extended to 3 o'clock p.m., Monday, December 1st. C. J. Brown, city clerk.

RAILWAYS

Bowmanville, Ont.—Ratepayers passed Hydro-radial by-law.

Guelph, Ont.—W. H. Breithaupt, president of the Waterloo and Wellington Ry., of Kitchener, submitted to Mayor Carter a proposal to connect Guelph and Kitchener with a line that would run through Bridgeport, Bloomingdale, New Germany and Marden, a distance of 15½ miles. There would also be a bridge over the Grand river. Estimated cost, $280,000.

Halifax, N.S.—According to a statement made by Grant Hall, vice-president of the C.P.R., who recently made a tour of inspection over the Dominion Atlantic Ry., in company with General Manager George Graham, before long the present light rails on the D.A.R. will be replaced by heavier standard steel.

Hamilton, Ont.—Board of Control recommended to city council that by-laws for $607,173 for the construction of the local end of the Guelph-Galt-Hamilton Hydro radial line be submitted to the electors in January. A resolution was also passed, urging Sir Adam Beck to start construction on the lines which have been authorized.

Hamilton, Ont.—Plans of the proposed Hydro radial line from Guelph and Elmira to this city have been filed with the city clerk. The cost is estimated at $6,530,000. The plans provide for a terminal for all radial lines on James St.

Oshawa, Ont.—Ratepayers passed Hydro-radial by-law.

Quebec, Que.—Dominion government will shortly take over the Quebec and Saguenay Ry.

Scarboro Tp., Ont.—Electors passed Hydro-radial by-law.

Toronto, Ont.—Ontario Railway and Municipal Board have given a decision overruling the objections raised by the Toronto and York radial railway to the city of Toronto constructing the Mount Pleasant railway line. The plans for the latter were also approved by the board's engineer.

FACTORIES AND LARGE BUILDINGS

Bedford, N.S.—The sawmill and box factory owned and operated by Moirs, Limited, was destroyed by fire recently. Building was insured for $50,000.

Belleville, Ont.—The Judge Jones Milling Co. is constructing a large elevator here.

Brantford, Ont.—Brantford Golf and Country Club plan enlargement of clubhouse.

Brantford, Ont.—Plans are being prepared for two wing extensions to the Collegiate Institute.

20-Year Barrett Specification Roof on Foundry Bldg. of Thos. Davidson Mfg. Co., Ltd., Montreal. Can. Arch.: A. W. Robinson, Montreal; Gen. Con.: A. F. Byers & Co., Montreal; Roofers: Hickey & Aubut, Montreal.

A 20-Year Guaranty Roof protects this Canadian Foundry—

A foundry roof has more than weather to withstand. It must be able to resist the intense heat of the furnaces underneath, and showers of red-hot sparks from above.

When the roof on the foundry building shown above was completed we gave the owners a Surety Bond *guaranteeing* their roof to be free from maintenance expense for *20 years*.

In this case the Surety Bond was hardly necessary, for the Thos. Davidson Mfg. Company, Ltd knew from experience what service to expect, as the following paragraph from their letter to us shows:

> "You will no doubt be interested to know we have insisted on Barrett Specification Roofs on all our plants, as our experience has proved it to be in every way satisfactory."

Not only are Barrett Specification Roofs "in every way satisfactory," but they cost less per-year-of-service than any other type of permanent roof, and they take the base rate of fire insurance.

20-Year Guaranty

So sure are we of the service Barrett Specification Roofs will give *under the most severe conditions*, that we are prepared to *guarantee them for 20 years*, in all towns of 25,000 or over, and in smaller places where our Inspection Service is available provided they are 50 squares or more in area. The guaranty costs you nothing. We merely require that our Specification dated May 1, 1916, shall be strictly followed and that we have an opportunity to send inspectors to watch the job during construction. The guaranty is a Surety Bond issued by a well-known fidelity and guaranty company.

Copies of The Barrett Specification, with roofing diagrams, mailed free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Brantford, Ont.—Ratepayers will vote on erection of following:—An addition to the Brant Sanatorium, new isolation hospital, extension to the General Hospital, and two additional wings to the Collegiate Institute.

Calgary, Alta.—An annex will be built to the General Hospital. Address, R. J. Crichton.

Calgary, Alta.—Order-in-council has been passed by Dominion government, authorizing loan of $120,000 to the city for the purpose of erecting an annex to the General Hospital.

Calgary, Alta.—Plans will be prepared at once by provincial government for an Institute of Technology to be erected here. Minister of Education, Hon. Geo. P. Smith, Edmonton.

Campbellton, N.B.—The Rosebury Street School was damaged by fire to the extent of $25,000.

Charleswood, Man.—The municipal council will submit to the ratepayers a by-law providing for the borrowing from the Provincial government of $50,000 to be used for the building of houses. Clerk, Alex. B. Blakely.

Creelman, Sask.—Steps are being taken for the establishment of a union hospital here. Secretary-treasurer, C. W. Williams.

Edmonton, Alta.—Beatty Bros., Ltd., of Fergus, Ont., will erect a $200,000 warehouse on the corner of 109th St. and 103rd Ave. Additional western branches will be opened in Vancouver and Regina early next year. President, George Beatty.

Edmonton, Alta.—General contract for erection of city's main telephone exchange has been let to J. Dunlop for $80,468; the plumbing and heating contract to Lockerbie and Hole for $12,723, and the electrical work to Bert L. Perry, Ltd., for $2,546, all of this city.

Edmonton, Alta.—A delegation from the municipalities of Alberta convention asked Premier Stewart that steps be taken to secure Alberta's share of the $25,000,000, which the Dominion government has set aside for the provincial housing scheme, and to make it available for the purpose intended. Alberta's share on the population basis was placed at $1,500,000. The premier expressed his willingness to take the matter up, but said that a provincial scheme might be devised that would be even better for the local situation than that offered by the Dominion.

Edmundston, N.B.—Fraser Companies, Ltd., plan erection of a large saw mill near Edmundston.

Galt, Ont.—Work has started on a 142 by 32 ft. extension to the machine shop, and 44 by 26 ft. addition to the moulding shop of the Perfect Machinery Co. Brick construction.

Glace Bay, N.S.—The Y.M.C.A. will erect a new building. Secretary, Capt. Watt.

Glace Bay, N.S.—The School Board rejected all tenders received for the new central school building. The board will now supply all material and work will be in charge of Frank McSween. Tenders for excavating have been called.

Halifax, N.S.—The Crane Company, an American hardware concern, proposes to erect a large building here.

Hamilton, Ont.—Damage to the amount of about $60,000 was done recently by fire and water to the John Lennox building here.

Hamilton, Ont.—A million-dollar company which proposes to erect a large Pantages theatre, has been organized and will seek incorporation at once. Address George Stroud, manager, Savoy Theatre, Hamilton.

Hamilton, Ont.—Excavating contract let to A.Cope & Son in connection with erection of first unit of Firestone Tire and Rubber Company's plant. Designs for building not completed yet, and contracts for same not let. Manager, O. W. Cook.

Hamilton, Ont.—Permits have been issued to W. H. Cooper for a brick factory for the Canadian Carbonate Co., on Simcoe St. W., at a cost of $10,000, and to W. H. Yates for an addition to plant for the Bell Thread Co., Huron St., $15,000.

Hamilton, Ont.—F. Guest, head of the company owning and operating the Strand, Empire and Queen's theatres in this city, has purchased a site for a large combination building to consist of a motion-picture theatre, stores and private apartments.

Harriston, Ont.—A by-law authorizing the erection of a memorial hall may be submitted to ratepayers at next election.

Lethbridge, Alta.—At a representative gathering here the necessity of a Normal school for the southern portion of the province was urged on the government.

London, Ont.—At the January elections the ratepayers will vote on a by-law authorizing the erection of a $100,000 memorial hall.

London, Ont.—Building permit issued to the McClary Mfg. Co., for erection of a three-story shop building, 61 by 183 ft., on Adelaide St. Estimated cost, $55,600.

Mallorytown, Ont.—Plans for the erection of a consolidated school have been drawn by Benjamin Dillon, architect, Brockville, Ont.

Montreal, Que.—A public hall is to be erected at once in the rear of the station at Springfield Park. Address Major G. P. Vanier.

Montreal, Que.—A new church, to be known as "Trinity Memorial Church," will be erected in Notre Dame de Grace. Rector, Col. the Rev. Canon J. M. Almond.

Montreal, Que.—The necessity for the immediate extension of Peel Street club house is being urged by President W. R. Grainger, of the Montreal Amateur Athletic Association.

Montreal, Que.—The main building of the University of Montreal, better known as Laval University, was destroyed by fire on November 22nd. The damage is estimated at $400,000.

Montreal, Que.—A private bill will be introduced at the forthcoming session of the legislature for incorporation of a new hospital under the name of St. Mary's Memorial Hospital. Those asking incorporation are Lord Shaughnessy, Hon. C. J. Doherty and Dr. Francis Devlin.

Oshawa, Ont.—The Chamber of Commerce and Women's Institute are considering the advisability of building a community hall.

Parry Sound, Ont.—Town council may erect an aerodrome.

Pembroke, Ont.—The Pembroke Cottage Hospital Association plans erection of addition to hospital. President, Andrew Johnston.

Pitt Meadows, B.C.—Council will erect a recreation hall at a cost of $1,500. Councillor, R. H. Sharpe.

Port Arthur, Ont.—Board of Education is seeking a site for a new collegiate institute. Chairman, Mr. Young.

Port Haney, B.C.—A new three-room school is planned at a cost of about $15,000. Trustee, Mr. Platt.

Port Moody, B.C.—The British Columbia Refinery Co. is building a new boiler-house. Contractor, J. C. McRae.

Quebec, Que.—The factory of J. A. Scott, St. Valier St., is to be repaired. Cost $1,100.

Quebec, Que.—A large sawmill belonging to the Jackman Lumber Company was entirely destroyed by fire. Loss, $125,000.

Quebec Que.—A three-story brick building will be erected at the corner of St. Roch and des Fosses Sts. Address Fitch, Phillips, Ltd.

Regina, Sask.—Permit has been granted for the new community hall for the Imperial Oil Company. The building will be two stories, 91 by 66 feet, and will cost $17,000. Frame construction.

Renfrew, Ont.—The construction of a sawmill of reinforced concrete has been started by Gillies Bros., Ltd. All of the machinery is to be electrically-driven. A. F. Byers & Co., engineers and contractors, of Montreal, have the work in hand.

St. Thomas, Ont.—A campaign for the advancement of the proposed memorial hospital for St. Thomas and Elgin County is being launched. Chairman of Special Committee, Dr. J. D. Curtis.

St. Thomas, Ont.—General contract let to A. E. Ponsford, Ltd., St. Thomas, for erection of new building for Molsons Bank.

Sarnia, Ont.—McGibbons Limited will enlarge their lumber building.

Sarnia, Ont.—The Holmes Foundry Co., Ltd., have let the contract for a 200-ft. addition to their present foundry building.

Saskatoon, Sask.—Building operations on the new $35,000 rink will begin at once. Architect, David Webster.

Sherbrooke, Que.—Sherbrooke Housing Company has purchased a property for the erection of a model city, on which a hundred houses will be built to accommodate the employees of the new Canadian Connecticut Cotton plant here.

South Devon, N.B.—The Nashwaak Pulp and Paper Co. has purchased a new pulp and paper mills site here. The company now has under construction on the Nashwaak River at Marysville a large concrete dam from which, it is understood, electric power will be developed for the proposed mill at South Devon.

Sudbury, Ont.—Fire damaged the high school to the extent of several thousand dollars.

Sydney, N.S.—E. Le Roi Willis is considering the formation of a company with the object of erecting a hotel in Sydney.

Timiskaming, Que.—It is rumored that contract No. 3 in connection with the construction of the Kipawa Fibre Co.'s new paper mill here has been awarded to the G. A. Fuller Construction Co. This contract is said to cover the extension of all the buildings constructed, and it is reported that it amounts to about $3,000 000 additional work.

Toronto, Ont.—Canadian General Fire Extinguisher Co., Chelsea Ave., propose to erect a large plant.

Toronto, Ont.—T. Kinnear & Co., 49 Front St. E., will erect a $150,000 warehouse on Dupont Street.

Toronto, Ont.—"King Fashion" Tailors, 101 Yonge St., will erect a 6-story building at 93-99 Bathurst St.

Toronto, Ont.—Tender of Lewis Le Grow for drain work at Kitchener School, $2,747, accepted by Board of Education.

Toronto, Ont.—City council adopted recommendation for erection of $20,000 fire station in Ashbridge's Bay industrial district.

Toronto, Ont.—A two-story moving picture theatre will shortly be erected on Danforth Ave., north side, east of Greenwood.

Toronto, Ont.—Willard's Chocolates, Ltd., will erect a large new building at the northeast corner of Dupont St. and Manning Ave.

Toronto, Ont.—Plans for two additional wings to Earl Grey School, Jones Ave., have been approved, and work will commence shortly.

Toronto, Ont.—City council passed the recommendation that the people be asked to vote $1,000,000 for a live stock arena, to be erected at the Exhibition grounds.

Toronto, Ont.—The harbor commission will hold a conference with Col. Barker, V.C., regarding the establishment of a municipal airdrome and a suitable site for same.

Toronto, Ont.—The Orange Society is endeavoring to raise $300,000 for the erection on Yonge St., near Richmond Hill, of Royal True Blue and Orange Home for Orphans.

Toronto, Ont.—City council granted permission to Dr. D. Campbell Meyers to alter the interior of his neurological hospital at 72 Heath St. W., so as to convert it into an apartment house.

Toronto, Ont.—The following permits have been issued: E. L. Ruddy Co., studio building, two-story brick, 315-25 Spadina Ave., $25,000; A. D. Waste and R. H. Bishop, two-story brick office building, 929-31 West Bloor St., $16,000.

Toronto, Ont.—The tenders for the new Salvation Army building on Dufferin St. have proven to be much higher than was expected and the plans will be considerably modified. It was estimated that the sum of $25,000 would be sufficient, but the lowest tender was $28,000.

Toronto, Ont.—Board of Education let following contracts in connection with erection of an addition to Parkdale Collegiate Institute: Asphalt mastic to Construction Steel Supply Co., Ltd., at $2,526.25, and for ornamental iron work to the Canadian Ornamental Iron Co., Ltd. New tenders will be called for plastering.

Toronto, Ont.—The following building permits have been granted:—H. Burnside, garage, Danforth Ave., near Ashdale Ave., $15,000; Globe Printing Co., addition to printing office, 60 Yonge St., $35,000; Secord and Howie, garage, 2811 Dundas St. West, $17,500; Jefferson Glass Co., factory, 388 Carlaw Ave, $55,900.

Valois, Que.—The Citizens' Association is making arrangements for the erection of a memorial hall.

Vancouver, B.C.—Plans of Sharpe and Thompson for proposed natatorium and amusement hall at English Bay were submitted to the parks board.

Vancouver, B.C.—The B.C. Fir and Cedar Lumber Co. will reconstruct its plant which was recently destroyed by fire.

Vancouver, B.C.—Two new branches of the Royal Bank of Canada will shortly be established in this city. In addition to this, one of the present branches will be extended to approximately double its present size.

Vancouver, B.C.—There will be an expenditure of $600,000 made by the Imperial Oil Co. for the plant at Ioco, on Burrard Inlet. The extensions include additions to the treating plants, acid restoring plants, and refinery.

Vancouver, B.C.—Permits granted to the Independent Van and Storage Company, 410 Nelson Street, for erection of garage at a cost of $2,000; and to the Dominion Construction Company, Granville Island, for warehouse to cost $3,500.

Victoria, B.C.—Tenders will be received at the office of T. H. White, chief engineer, C.N.P. Rly., Vancouver, B.C., until 12 o'clock noon, November 29th, 1919, for the supply of all labor and materials for the erection of: Five-stall engine house and machine shop and turntable foundation at Songhees Reserve, Victoria, B.C. Plans and specifications may be obtained at the office of the District Engineer, Victoria, B.C.

Walkerton, Ont.—Cloe Clark has decided to build a one-story theatre. Estimated cost, $5,000.

Walkerville, Ont.—Representatives of Walkerville and Ford G.W.V.A. and Walkerville town council will confer on the request of the returned men for a grant of $40,000 toward a war memorial hall.

Whitby, Ont.—Ratepayers passed by-law to spend $60,000 on new school buildings. Clerk, Joseph White.

White Rock, B.C.—A movement is on foot for erection of a memorial club house.

Windsor, Ont.—Cross & Co., manufacturers of contractors' and builders' supplies, plan additions to their factory next spring.

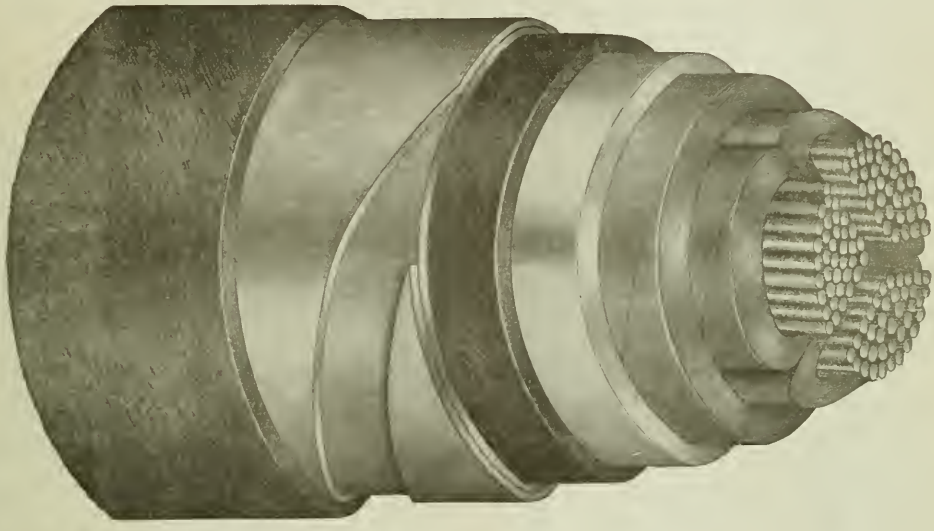
Winnipeg, Man.—Marcus Loew will build a $600,000 theatre in Donald St., construction to start in March. Architect, T. W. Lamb, 263 Yonge St., Toronto.

Winnipeg, Man.—E. H. Rodgers, building inspector, estimates that building permits next year will total $10,000,000. This year the permits will run close to $3,000,000. The total for 1918 was $2,000,000.

MISCELLANEOUS

Agassiz and Rosedale, B.C.—Tenders will be received by the Honorable the Minister of Public Works up to noon of Wednesday, December 3rd, 1919, for the erection and completion of ferry landings near Agassiz and Rosedale, B.C., on the Fraser River. Plans and specifications may be seen at the Department of Public Works, Parliament Buildings, Victoria, B.C., and at the office of the District Engineer, Van-

PAPER INSULATED CABLES



The above is a full-size illustration of a 350,000 C.M. 3-conductor 12,000 volt Paper-insulated Lead-covered Steel Tape Armoured Cable. Overall diameter 3.62 inches. Manufactured by us to the Specifications of the Hydro-Electric Power Commission of Ontario.

Eugene F. Phillips Electrical Works, Limited

Head Office and Factory: MONTREAL

Branches: Toronto Winnipeg Regina Calgary Vancouver

couver, B.C. A. E. Foreman, public works engineer, Public Works Department, Victoria, B.C.

Bamfield and Ucluelet, B.C.—Tenders, addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Monday, December 22nd, 1919, for repairs to wharves at Bamfield and Ucluelet, Comox-Atlin District, B.C. Plans can be seen and specification obtained at the Department of Public Works, Ottawa; at the offices of the District Engineer, Victoria, B.C., and at the post-offices, Bamfield and Ucluelet, B.C.

Brandon, Man.—Public Utilities Commission will take up the question of constructing a dam in Assiniboine River.

Bridgeburg, Ont.—The Reliance Manufacturing Co. has just been incorporated with a capitalization of half a million dollars. The concern will be located on Lewis St., and will manufacture electrical goods.

Glace Bay, N.S.—Repairs to the breakwater will be undertaken at once by the Department of Public Works, Ottawa. Estimated cost, $6,000. Engineer, Mr. Coultee.

Halifax, N.S.—The Canadian Incinerator and Furnace Co., Ltd., Toronto, have just completed the installation of three oil-burning furnaces for the Halifax shipyard. The same firm previously installed at the same yard two large furnaces which are being continuously used in bending frames and plates for the four new ships now under construction here.

Oshawa, Ont.—Town council authorized the construction of certain concrete sidewalks, water mains and sanitary sewers. Town engineer, G. W. Worden.

Ottawa, Ont.—Joint stock companies incorporated last week include the following: Baldwin Canadian Steel Corporation, Ltd., capital, $500,000, Toronto; National Steel Car Corporation, Ltd., capital, $500,000, Toronto; Elliot Machinery Co., Ltd., capital, $250,000, Belleville Ont.

Owen Sound, Ont.—Tenders, addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Friday, December 12th, 1919, for the reconstruction of a wharf at Owen Sound, Ont. Plans can be seen and specification obtained at the Department of Public Works, Ottawa; at the office of the District Engineer, Equity Building, Toronto, Ont., and at the Post Office, Owen Sound, Ont.

St. John, N.B.—Tenders, addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Tuesday, December 9th, 1919, for the construction of grain conveyor equipment, at Berth 15, St. John Harbor, N.B. Plans can be seen and specifications obtained at the Department of Public Works, Ottawa; at the offices of the Engineer-in-charge, St. John, N.B.; the District Engineers, Shaughnessy Building, Montreal, Que., and Equity Building, Toronto, Ont.

Sorel, Que.—Dominion Department of Public Works let contract for reconstruction of wharf to Onesime Poliquin, Portneuf, Que.

Sydney, N.S.—Dominion government will erect a new terminal wharf here at a cost of $100,000.

Vancouver, B.C.—Five new steel ships of 9,500 tons each will be constructed at the G. M. Standifer Shipbuilding Co. yards during the next six months.

Vancouver, B.C.—It is rumored that the Dominion government is contemplating the purchase of the Hastings Mill site for harbor development purposes.

Vancouver, B.C.—The Great Northern Railway Co. are planning an addition of about 500 ft. to their present docks in this city. Assistant traffic manager, M. J. Costello.

Victoria, B.C.—Certificates of incorporation have been granted to the following new companies:—Marsh-Bourne Construction Co., Ltd., Vancouver, capital, $250,000; Maddison Salvage Corporation, Ltd., Vancouver, capital, $10,000.

Winnipeg, Man.—The establishment of a wireless telephone system throughout the settlements in northern Manitoba, at an estimated cost of from $25,000 to $30,000, will be recommended to the provincial government by Prof. R. G. Wallace, commissioner for this territory.

Tenders Called For

CITY OF NORTH BATTLEFORD, SASK.

TENDERS FOR POWER PLANT EQUIPMENT

Sealed tenders, addressed to the undersigned, and marked, "Tender for Power Plant Equipment," will be received up to 5 p.m. on Saturday, December 6th, 1919, for two 250-h.p. Water Tube Steam Boilers, one Sheet Metal Stack, 50" x 60', and a quantity of Metal Smoke Flue.

Plans, specifications and all further information may be obtained on application to M. D. Cadwell, Superintendent of Utilities, City Hall, North Battleford, Sask.

ROBERT FARQUHARSON, City Clerk.
The City Hall, North Battleford, Sask.,
November 18th, 1919. 383

CITY OF SASKATOON

SALE OF 750 K.W. GENERATOR SET

The City of Saskatoon invites offers for the purchase of the following electrical machinery:—

One 26" x 48" x 30" Roll Armstrong Vertical Cross-compound Engine, direct-connected to 750 k.w. General Electric two-phase, 2,300-volt, 60-cycle Generator, complete, with surface condenser, air-pump, etc.

This unit is being offered for sale in order to provide room for a larger set, is in first-class running condition, and can be shown in operation at the City Power Plant.

Tenders to be delivered to the undersigned on or before 12 noon on Friday, the 12th day of December, 1919.

C. J. YORATH,
382 City Commissioner.

HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO

RAILWAY DEPARTMENT

SUPERSTRUCTURE OF HIGHWAY BRIDGE ACROSS WELLAND RIVER AT CHIPPAWA, ONTARIO

ADVERTISEMENT FOR TENDERS

Sealed tenders will be received until November 28th, 1919, at 12 o'clock noon, addressed to Sir Adam Beck, Chairman, Hydro-Electric Power Commission of Ontario, 190 University Avenue, Toronto, Ontario, and marked "Tender for Chippawa Highway Bridge." Plans, specifications, and other information may be obtained by applying to the office of Chief Engineer. The Commission reserves the right to reject any or all tenders received.

Hydro-Electric Power Commission of Ontario.

W. W. POPE,
Secretary.

Dated at Toronto, November 14th, 1919.

The time for acceptance of the above tenders has been extended to 12 o'clock noon, December 6th, 1919.

Hydro-Electric Power Commission of Ontario.

W. W. POPE,
Secretary.

Dated at Toronto, November 24th, 1919. 375

A new company known as the Trading Engineers, Inc., has been formed by a number of South American, United States and Canadian engineers.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Report Presented by Status Committee to J.C.T.O.

Complete Text of Draft Bills Formulated for Joint Committee of Technical Organizations by Its Status Committee (H. G. Acres, Chairman) as Model Legislation for Uniform Provincial Acts — Report of Status Committee, Introductory to Draft Bills, Discussing Need for Legislation

THE phrase, "Status of the Engineer," may be roughly defined as the reputation and degree of prestige which the engineer enjoys or deserves in the eyes of his fellow-citizens, having due regard to the value of his services to the public at large.

Status involves two essential factors: First, recognition of engineering as an essential profession, through the agency of both public sentiment and legal enactment; and, second, an adequate scale of remuneration for services, as compared with other professions and with trades.

These two factors may be shortly defined as "recognition" and "remuneration."

In handling the above two phases of this problem it is necessary to determine whether they are of equal importance, or whether one takes precedence over the other, and, finally, if the latter is the case, to fix the order of precedence.

The argument under this head can be conveniently established by analogy. From the bald standpoint of remuneration, engineering service is just as properly a commodity as manual labor, and the revenue derived from its sale is governed first by the number of purchasers who need it, or think they need it, and second, by the amount of such commodity the individual purchaser can be prevailed upon to absorb in place of some other commodity which he has used previously in place of it. There is no virgin market for engineering services. It must compete in long-established markets with other commodities which it must supplement or displace.

The organization of the trade union was essentially an expedient to advertise the worth and importance of a commodity which, for lack of a better term, may be called "manual labor." The unity of interest created by such organizations enabled the manual worker to make use of the strike as an additional advertising expedient, and as a result of the forced recognition thereby realized, he was able to demand a higher price for the commodity he produced, and by the sale of which he existed.

Commodity Must Be Recognized

There was no virgin market for shredded wheat. A carefully planned and extensive advertising campaign was instituted to prevail upon the public to eat shredded wheat instead of oatmeal porridge. Through this expedient recognition of shredded wheat was grafted on the public mind. It was educated to think it needed shredded wheat, and thereafter remuneration accrued to the Shredded Wheat Co., with resulting prosperity.

Whether the commodity is "manual labor" or whether it is "shredded wheat," it must be recognized before it can be sold. The greater the public need, whether fundamental, as in the case of manual labor, or cultivated, as in the case of shredded wheat, the greater and more certain will be the remuneration.

Considered from the non-æsthetic standpoint as a commodity, engineering service must conform to the same economic laws, and recognition must of necessity be the precursor of remuneration. This proposition would seem to be amply vindicated by the fact that it applies to any individual consultant who has a large clientele, and who can demand a large fee for his services. Almost invariably it will be found that such a man has demanded a higher price for his services as their value became more fully recognized and established. He first obtained recognition through the medium of some form of advertising, which educated an ever-increasing body of the public to need him, or think they needed him, and remuneration followed as a matter of course.

Recognition Precedes Remuneration

The problem of establishing the status of the engineer therefore resolves itself essentially into devising some means of applying to engineers as a class the laws which have operated successfully in the case of the engineer as an individual. In other words, engineering service generally must have recognition commensurate with its value to the community at large before adequate remuneration can be obtained for engineers as a class.

If, therefore, the engineer is to take the place in the community to which he is entitled by virtue of his attainments and the high class of service he can render, the primary requirement is recognition.

Recognition is obtainable by two general methods, more or less distinct—namely, by general publicity and by legislation.

The ordinary means of obtaining publicity for the engineering profession are many and diverse. The outstanding requirement under this head is for engineers as a class to participate in the affairs of national and provincial government. This contention is so fundamentally sound and has been so often repeated, and so generally recognized, that it is not necessary to enlarge upon it. It is true beyond the possibility of argument that the status of the engineer as related to national affairs cannot be advanced or conserved unless engineers themselves exercise active governmental functions, and pass, as well as frame, the laws relating to or incidentally affecting the profession. The civil service bill now before the Dominion house is a luminous exemplification of this condition. This bill is of vital importance as related to the status of engineers as a class. It seeks to give engineers in the civil service a professional status as distinguished from the status of the ordinary departmental clerk, and also to establish an advanced salary scale. It has been framed with the assistance of engineers, but it is fairly safe to say that there is not a single practising engineer in the House of Commons to argue and support the passing of this bill. Its very doubtful fate rests mainly in the hands

of lawyers, doctors and farmers. The probable opposition and non-support of such men cannot be charged so much to active enmity as to excusable ignorance and lack of interest, for which condition engineers themselves are mainly responsible.

Among other channels of publicity may be mentioned the active participation of engineers in town planning, housing and settlement problems, and in developing such problems into specific schemes for government ratification and administration. Conditions governing publicity in the broad sense demand that engineers must seek out and identify themselves with all beneficent movements and projects, particularly those which have a wide public appeal.

Unionism Not Proper Medium

Finally, there comes the question of unionism as a means of obtaining recognition through publicity. The various technical organizations of this country could assume the essential functions of a trade union if their constitutions were so amended as to permit them to adopt the principle of collective bargaining and to promulgate strikes. This method of obtaining recognition is without doubt repugnant to the majority of engineers, and, while some transitory benefit might be derived by junior engineers, the general effect would be a very material lowering of the status of the engineer in his own estimation, and in the estimation of the public from whom he derives sustenance. It is difficult to conceive of a town manager, a commissioner of works or a consulting engineer participating in a strike, or to imagine that the diverse, and at the same time interlocking, activities of engineers could be so grouped and segregated as to render them susceptible to the principle of collective bargaining. The proper sphere of activity for any man who wishes to use collective bargaining and the strike as an economic weapon is in a trade, and not in a profession. The value of creative engineering work and the work incidental to the solution of engineering problems in general must be appraised on an individualistic and not on a collective basis. Unionism does not therefore appear to be a proper medium of publicity for engineers to employ as a means of obtaining recognition.

The other factor involved in the problem of recognition is legislation. In its relation to the matter of recognition, legislation should be considered as a defensive weapon, as distinguished from publicity, an offensive weapon. In other words, publicity should be the sword, and legislation the shield, of the engineering profession.

Legislation For Public Welfare

The primary function of all legislation is the protection of the public. If this principle is rigidly applied to any engineering legislation that may be framed, it will be found that the engineer has received his full measure of protection, not as an engineer, but as a part of the body politic. All that engineers as a class are entitled to is some effective means of protecting their professional reputation and prestige. Legislation can certainly be framed to meet this end, and so framed as to be for, and not at the expense of, the public weal.

Anything beyond this must be defined as "class legislation," which, in the final analysis, does not protect, but stigmatizes, and would ultimately force the engineer into the position of having to protect his legislation instead of having his legislation protect him.

On the basis of the above premises, therefore, it should be possible to roughly outline the salient features which properly framed engineering legislation should embrace.

The more important features of such legislation are cited hereunder.

Cognizance of Existing and Future Conditions.—Under this head must be considered the comparative youth of engineering as a recognized profession, and the very great difficulty of so exactly defining the functions and activities of an engineer that such definition would hold in law. It would appear that the most practicable way of overcoming this difficulty would be to vest considerable discretionary power in any board or commission which might be delegated to administer the law. This discretionary power would be exercised in respect of such matters as the recognition of engineers practising at the time the law comes into effect, the classification of engineers according to specialties, the formation of partnerships, the granting of exemptions, the fixing from time to time of standards of qualification, the revocation of privileges, and the enforcement of penalties.

Malpractice.—The public and the competent engineer should be protected from wilful or involuntary malpractice. It is just as important to have healthy and efficient engineering structures built by responsible and competent engineers as it is to have the health and efficiency of the individual citizen maintained by competent medical supervision. If the protection of the law is necessary in one case in the public interest, it is equally necessary in the other.

Conservation of Man-Power.—The necessity for conserving and developing national resources to the utmost is receiving world-wide recognition at the present time. The development and conservation of natural resources can reach a high stage of efficiency and economy only by giving primary consideration to the conservation and development of man-power. The man-power of the province of Ontario is developed in one direction by an elaborate system of public education, consisting of primary schools, high schools, collegiate institutes and a government-supported university. The province, therefore, expends a considerable sum of money on every engineer it graduates from the university, but under present conditions ceases thereafter to assume any responsibility for his professional advancement or to provide for any return on the investment made in his behalf. Obviously, this return could best be realized by applying the engineering man-power so created to the development of provincial industry and to the conservation and development of the natural resources of the province. Such procedure would be eminently in the public interest, and any enactment leading to its consummation would come well within the limits of permissible engineering legislation.

Development of Home Trade.—This phase of the situation is closely allied to the problem of conserving man-power.

The surest indication of a country's prosperity is a favorable trade balance, which in turn is measured by the volume and extent of its home trade. The condition of the home trade of any country is solely dependent upon the volume and diversity of the commodities it can produce for the needs of its own citizens. This condition applies as properly to the service of its engineers as to the products of its fields, and any measures taken to provide that engineering service be purchased within the province would be in the public interest in so far as the development of home trade is concerned.

International and Interprovincial Comity.—Under this head comes the important feature of so framing engineering legislation as to obviate any onerous restrictions on the practice of the profession by bona fide engineers entering the province temporarily, or with the intention of becoming permanent or naturalized citizens, and in general to place the engineering profession in the province beyond the fear of reprisals, or other demonstrations of ill-feeling, on the part of other countries or provinces. This feature is more or less in direct opposition to any drastic enactments which might be considered in relation to the conservation of man-power and the development of home trade. These three features must, therefore, be considered together in an effort to effect a reasonable compromise.

Assuming the above general specifications as a ground work for the framing of a law which, while adequately establishing and protecting the status of the engineer, will at the same time be in the public interest, it remains to discuss the general form in which such legislation might be presented.

All existing and proposed legislation of this class involves the principle of registration, and the issue, in some form or other, of a license to practise. It is significant that all engineering legislation recently enacted vests the administrative control of registration and the issue of licenses in the government, and not in a council or board appointed by the engineers themselves. Herein lies the basic distinctio

between "class" legislation and "popular" legislation, as applied to the particular subject under discussion.

The most comprehensive piece of legislation now in force with reference to this subject is that incorporated in the Civil Administrative Code of the State of Illinois. In this case the administrative function is vested in a department of registration and education, and the powers of this department are made sufficiently broad and general to permit it to exercise its functions not only in respect of all professions, but all trades. The regulation of any specific profession or trade is accomplished in two ways—either by a special act making regulation compulsory, or by application to the department of registration, voluntarily requesting regulation. Two instances of the first alternative are the structural engineers and the architects of Illinois, in respect of both of whom compulsory regulating acts were introduced in the state legislature during the present year.

Two pieces of legislation, the first covering the general principle, and the second the specific case, constitute what appears to be an adequate and satisfactory means of improving and fixing the status of the engineering profession in Illinois, while at the same time they express the popular will.

The latest development in legislation of this class is the Michigan Registration Act. In this act an effort is made to devise workable legislation covering the combined activities of engineers, architects and surveyors. While it lacks the complete generality of the dual enactments of the State of Illinois, it similarly vests administrative control in the government, thus classing the act as popular legislation, and it furthermore avoids the dangerous practice of attempting to rigidly define by legal enactment the professional functions and activities of engineers, architects and surveyors. Instead, it leaves all matters relating to the classification and status of applicants for registration to a registration board which is created under the terms of the act. While the exercise of this discretionary power may possibly lead to anomalies and abuses, it will be much easier to remove them by subsequent amendments to the act than to revise, extend or condense, by amendment, the legalized definition of a civil engineer, a mining engineer, an architect or a surveyor.

The likelihood of an engineering act becoming law is largely dependent on the generality and breadth of its application, and on the basis of this test the two Illinois acts have more of the aspect of popular legislation, and have a wider public appeal, than the single Michigan act. Consequently, while it might not be proper to frame a general registration act to cover trades as well as professions, it would seem advisable to consider the adoption of the Illinois principle in so far as engineering and the allied professions are concerned. With legislation so limited for the time being, it could later be enlarged by amendment to include all professions and technical occupations, should it ever be necessary in the public interest to do so.

Based upon the above premises and specifications, it should now be possible to tentatively frame the terms of an act in sufficient detail to furnish ground for discussion.

TITLE: An Act to regulate the practice of professions and allied technical occupations and to provide for the registration of persons engaged in practising the same.

Short Title.—"The Professional Registration Act."

Administrative Agency.—The creation of a Department of Registration under the jurisdiction of the Minister of Education and the creation of the office of "Director of Registration."

Functions of Department of Registration.—(a) To administer and enforce laws relating to the regulation of specific professions and technical occupations, and to formulate rules and regulations for administering the same and for the fair and impartial examination of candidates for registration.

(b) To establish and control the standard of preliminary education necessary for admission to training schools, colleges and universities.

(c) To provide, on appeal, for re-examination of candidates and for rehearings in the case of action to revoke a license or certificate where it appears that justice has not been done.

Specific Legislation.—Specific legislation for the regulation of any particular profession, technical occupation or branch thereof may be introduced (a) on the initiative of the Minister of Education, should he consider such procedure necessary in the public interest; or (b) by request, through the Minister of Education, of a majority of the persons engaged in such profession, technical occupation or branch thereof.

Certificates and Licenses.—To be issued by the Department of Registration.

Exemptions.—The provisions of this act shall not be enforceable in respect of the practice of law, medicine, dentistry and surveying, as long as the laws now regulating these professions and occupations continue in force.

Assuming that the above terms, properly elaborated, would meet the requirements of a general act, which, by virtue of its generality, would require a minimum of amendment in the future, the next step is to outline the terms which should be incorporated in such specific or subsidiary acts as might be required in the future to embrace all branches of engineering activity, having particularly in mind the fact that, as the status of the engineer improves and becomes more generally recognized, his various lines of professional activity will become more sharply defined and more uniformly susceptible of regulation. The most acceptable form for these subsidiary acts is one which will be of the same general type for all branches of engineering, so that they can be passed as parts of the general act, at any time, by order-in-council, on the authority of a house resolution.

It would be necessary for such an act to contain the following provisions:—

TITLE.—An Act to regulate the practice of.....
and to provide for the registration of.....

Short Title.—"The .....Registration Act."

Administrative Agency.—Under the general direction of and appointed by, the Department of Registration, a Board of Examiners, one of whom shall be a professor or associate professor of.....in the University of....., and four other members, who shall be.....of recognized standing, who have had not less than ten years of bona fide experience in the practice of....., and who have resided continuously in the Province of .....not less than five years

Functions of Board.—(a) To receive applications for registration, and, at their discretion, accept those which properly come under the classifications they are delegated to examine, and to reject or refer elsewhere such applications as do not; (b) conduct hearings on matters relating to the revocation of, or refusal to renew, licenses or certificates, and at their discretion to revoke or refuse to renew the same; (c) establish regulations and rules of procedure for the proper administration of the law; (d) examine into and fix if necessary the standard of personal qualifications of applicants.

Reciprocal Registration.—Provision must be made for registration of practitioners from foreign countries or other provinces.

Public Works.—Provision making it obligatory that construction and maintenance work on provincial and municipal works be handled by qualified registrants under this act, in so far as it applies.

Further necessary provisions of this act include professional qualifications necessary for registration, discipline and penalties, formation of partnerships, and exemptions.

All of the above provisions will be found assembled in the accompanying draft act. The ancillary act here submitted refers to structural engineers, it being understood that the idea is to provide for additional ancillary acts of the same general type, referring to architects, electrical engineers, etc., and included in the general act as Part One, Part Two, etc. It will be noted that a number of the clauses in this draft act have been taken bodily from the proposed professional act prepared by the special legislation committee of the Engineering Institute of Canada. While this

draft act is a model piece of legislation of its kind, it was not analyzed and discussed in this report because it is essentially class legislation; it is only susceptible of comparison as a whole with the draft act herewith submitted.

In conclusion, the members of the Status Committee wish to point out that the subject of this report has so many complex and intangible ramifications, and is so vulnerable as related to existing legislation and public sentiment, that they do not presume to impose their views on their professional colleagues as the last word in engineering legislation. Their best hope is that there may be sufficient of interest in this report to prompt the various organizations represented by the Joint Committee to combine their energies and thrash out the issue to a definite conclusion.

PROPOSED DRAFT

An act to regulate the practice of professions and allied technical occupations, and to provide for the registration of persons engaged in practising the same.

Part One

HIS MAJESTY, by and with the consent of the legislative assembly of the Province of , enacts as follows:—

1. This act may be cited as "The Professional Registration Act."

2. There is hereby created a Department of Registration, which shall be under the jurisdiction of the minister of education of the Province of , and which shall be presided over by an appointee of the said minister, who shall have the status of a deputy minister, and who shall be styled the "Director of Registration."

3. It shall be the duty of the minister under this act—

(a) To administer and enforce laws relating to the regulation of specific professions and technical occupations.

(b) To establish rules and regulations for the proper administering of such laws, and for the fair and impartial examination of candidates for registration.

(c) To establish and control the standards of preliminary education necessary for admission to training schools, colleges and universities.

(d) To provide, on appeal, for the re-examination of candidates, and for rehearings in the case of action being taken to revoke a license or certificate or impose a penalty, when it appears that full justice has not been done.

(e) In all matters relative to the interpretation and administration of this act or any ancillary act, to give due and proper consideration to the representations and advice of members of the respective professions and technical occupations or of accredited organizations therein.

4. Within thirty days after any ancillary act relating to the regulation of any specific profession goes into effect, the minister shall appoint a board of examiners consisting of not less than three and not more than five members, and shall designate the chairman thereof. Tenure of office shall be so regulated that there shall not be more than one regular appointment to the board in any one year. Should a vacancy occur for any reason other than the expiry of a regular term of office, the minister shall fill the vacancy for the unexpired term, but otherwise subject to the rules governing regular appointments.

5. Members of board of examiners shall not receive compensation for their services, but shall be reimbursed for travelling and other actual expenses arising out of the performance of their duties under this act, and also for clerical and other assistance.

6. Ancillary legislation for the regulation of any specific profession, technical occupation, or branch thereof, may be introduced (a) on the initiative of the minister of education, should he consider such procedure necessary in the public interest; or (b) by request, through the minister of education, of a majority of the persons engaged in the practice of such profession, technical occupation, or branch thereof.

All such legislation shall be of the same general form as the ancillary act included herein as Part Two.

7. Pending the ratification of the appropriate ancillary act by the legislative assembly, any profession, technical occupation or branch thereof may meantime be made subject to the terms of the Professional Registration Act at the request of the minister of education and by consent of the lieutenant-governor-in-council.

8. All certificates, licenses and other authorities shall be issued by the Department of Registration, over the signature of the director, and with the seal of the department attached.

9. The provisions of this act shall not be enforceable in respect of the practice of law, medicine, dentistry or surveying so long as the laws now regulating such professions and occupations continue in force, or otherwise than through the provisions of sub-section (b), section 6, of this act.

Part Two—Ancillary Act

An act to regulate the practice of structural engineering and to provide for the registration of structural engineers.

HIS MAJESTY, by and with the consent of the legislative assembly of the Province of , enacts as follows:—

1. This act shall be cited as "The Structural Engineers' Registration Act."

2. In this act, unless the context otherwise distinctly indicates:—

(a) The word "minister" shall mean the minister of education of the Province of .

(b) The word "department" shall mean the Department of Registration.

(c) The word "director" shall mean the director of the Department of Registration.

(d) The word "board" shall mean the board of examiners appointed under the provisions of the Professional Registration Act.

3. On and after the date upon which this act goes into effect it shall be unlawful for any person to practise, or attempt to practise, structural engineering in the Province of without a certificate of registration or license to practise under the title of registered structural engineer, as issued by the Department of Registration under the provisions of the Professional Registration Act.

4. The following persons and things are exempt from the terms of this act:—

(a) Draftsmen, students, clerks of work, superintendents and other assistants of registered structural engineers, not taking responsibility for their work other than to their immediate superiors.

(b) Superintendents of construction in the pay of the owner when acting under the immediate supervision of a registered structural engineer.

(c) Any person, mechanic or builder, when making plans or specifications for, or supervising the construction, enlargement or alteration of, any structure or building which is to be constructed by himself or his employees for his own use.

(d) Any corporation preparing plans and specifications, and constructing, erecting or building engineering, industrial or monumental structures under the supervision of the corporation, provided the chief executive officer of the corporation, or the officer who immediately supervises the preparation of the said plans and specifications, and the building of such structures, is a registered structural engineer.

(e) Any person employed in actual service in His Majesty's naval, military or aerial service.

5. For the purpose of this act the board of examiners shall consist of five members, one of whom shall be a professor or associate professor of structural engineering in the University of , and the other four members registered structural engineers in good standing, who have had not less than ten years' experience in their profession and who have resided continuously in the Province of not less than five years.

6. A person is qualified to receive a certificate of registration as a structural engineer, without examination:—

(a) Who can prove to the satisfaction of the board, within one year of making application for registration, that he is a resident of the Province of at the date of the passing of this act, and who is at that date, and has

been for not less than five years previously, practising as a structural engineer.

(b) Who may come to reside in the Province of , and who at such time is a duly registered structural engineer under any similar act in any other province of Canada; provided that he shall present credentials as to his good standing satisfactory to the board, together with an application for transfer of registry endorsed by the proper administrative officer of such other province.

(c) Who submits proof, satisfactory to the board, of qualifications possessed by virtue of experience, training, or examination by any other examining body of recognized standing.

7. Otherwise than as provided under section 6 of this act, all candidates for admission to registration must be at least twenty-three years of age, and must have been engaged for eight years in some branch or branches of structural engineering, and for at least six years of such term in the employ of one or more structural engineers of recognized standing; provided, that in the case of a graduate from a recognized engineering college, the full period of such service shall be reduced to six years, which period will include his term of instruction.

8. Candidates for admission to registration under the terms of section 7 of this act shall submit to an oral and written examination before the board on the theory and practice of engineering, specializing in one or more of the various branches if they so desire.

A candidate failing on examination may, after an interval of not less than one year, be re-examined if he so desires.

9. Examinations shall be held as often and at such places as the minister may direct, and the scope thereof and the methods of procedure shall be fixed by the board, subject to the approval of the minister.

10. Any person not residing in the Province of who is a registered structural engineer under a similar law of any other province of the Dominion of Canada, may obtain from the director a non-resident license to practise as a structural engineer in the Province of upon production of evidence of his registry in such other province, and upon payment of a fee, the amount of which shall be fixed by the board. In the event of such person being unable, by reason of emergency or neglect on the part of the director, or for any other good and sufficient reason, to obtain such license within three months of his making application therefor, he shall be entitled to practise as a structural engineer in the province for such period of three months without holding such license.

11. Any person who is employed as an engineer by a public service corporation, a private corporation, public utilities or government department, whose business is normally carried on in two or more of the provinces of Canada, and who is by reason of his employment required to practise as a structural engineer in other provinces than that of his residence, may so practise in the Province of without holding a non-resident license, or payment of a fee, providing such person can, on demand of the board, produce credentials satisfactory to the board, showing that he is a registered structural engineer under a similar law of some other province of Canada. It shall be the duty of such person to produce such credentials whenever so required by the board; provided, that any structural engineer who is a resident of some other province of Canada, in which there is no registration or similar law, may obtain a license to practise, subject to the discretion of the board.

12. Any person who is not a resident of Canada, but who is a member of any engineering or technical organization or society of standing recognized by the board, may obtain a license to act in an advisory or consultative capacity to, or with, a registered structural engineer; provided, that reciprocal privileges can be accorded to registrants under this act.

13. Structural engineers practising in the Province of who were accepted for active overseas service in the War of 1914-18, in the forces of Great Britain, or any of her allies, shall be entitled to registration under the terms of sub-section "a" of section 6 of this act.

14. In the case of two or more persons carrying on practice as structural engineers in co-partnership, only such members as are registered or licensed under this act shall individually assume the function of a structural engineer. One or more registered structural engineers may lawfully enter into partnership with one or more registered practitioners of any other class.

15. No registered structural engineer shall be barred, under any of the terms of this act, from applying for registration, and being registered, pursuant to the provisions of any other registration act which may now or hereafter be in force in the Province of .

16. The board shall appoint a secretary and adopt rules and regulations for its own organization, and for the examination and classification of candidates for registration, and the issue of certificates thereto, and for carrying out the provisions of this act, and may amend, modify and repeal such rules and regulations from time to time. Such rules and regulations and any amendments thereto shall be subject to the approval of the minister.

17. The board shall at its discretion determine whether the experience and qualifications of any applicant are such as to make him eligible for examination and registration as a structural engineer, and shall reject or refer elsewhere any application which, in its opinion, does not fall within this category.

18. All moneys and fees collected or received under this act shall be properly recorded and receipted for and deposited with the provincial treasurer, who shall keep the same in a separate fund to be drawn against only for the expenses of the board.

19. All moneys expended by the board shall be paid through the provincial treasurer on properly drawn vouchers, signed by the chairman and secretary of the board.

20. Persons desiring to obtain a certificate or license shall apply therefor to the director, in writing, upon blanks prepared and furnished by the department. Each application shall be accompanied by proof of the particular qualifications required of the applicant, and shall be verified by the applicant under oath.

When the provisions of this act have been complied with, the director, on report of the board, will issue to the successful applicant a certificate of registration or a license, as the case may be.

21. Every registrant or licensee under this act shall display his certificate or license in a conspicuous place in his principal office or place of business or employment.

Every registered structural engineer shall have a seal, the impression of which shall contain his name and the words, "Registered Structural Engineer, Province of ," with which he shall stamp all documents and plans.

22. Every registered structural engineer who continues in active practice shall, annually, on or before a date to be fixed by the board, renew his certificate of registration, or license, and pay the prescribed renewal fee. An expired certificate may be restored, at the discretion of the board, by the payment of a restoration fee.

A registered structural engineer who retires from active practice for not more than five years may renew his certificate upon payment of all lapsed renewal fees.

23. The board shall from time to time fix the scale of fees to be charged for the examination and registration of applicants, for the issue of certificates and licenses, for the renewal of certificates and licenses, and for the restoration of lapsed certificates and licenses, such charges to be at all times subject to the approval of the minister.

All fees shall be paid in advance of the issue of any certificate or license, and no such certificate or license shall be considered in force while any renewal or penalty obligation is charged against it.

24. The board may by a three-fifths vote revoke any certificate or license upon written notification to the holder

thereof, giving him not less than thirty days' notice of an opportunity for a hearing, upon proof that such certificate has been obtained by fraud or misrepresentation, or upon proof that the holder of such certificate or license has been guilty of malfeasance or gross incompetency in the exercise of his profession.

25. The department shall keep a record, which shall be open to public inspection at all reasonable times, of its proceedings relative to the issuance, refusal, renewal, suspension and revocation of certificates and licenses. This record shall also contain the name, number, place of business and residence, and date and number of the certificate or license, of every registrant and licensee with whom the board has dealt.

25. Each of the following acts constitutes a misdemeanor, punishable upon conviction by a fine of not less than $ nor more than $:—

(a) The practice of structural engineering, or an attempt to practise structural engineering, without a certificate of registration as a registered structural engineer, or a license issued under the several provisions of this act; each day of so practising, or attempting to so practise, shall constitute a separate offence.

(b) The making of any wilfully false oath or affirmation whenever an oath or affirmation is required under the terms of this act.

(c) The affixing of a registered structural engineer's seal to any plans, specifications, estimates or drawings which have not been prepared by him or under his immediate personal supervision.

(d) The violation of the provisions of section 21 of this act.

All fines and penalties shall inure to the Department of Registration, and shall be recoverable with costs under the provisions of the law respecting summary convictions.

27. On and after a date six months subsequent to the date upon which this act comes into effect, neither the province, nor any county, township, municipality or village shall engage in the construction or maintenance of any public work of a structural engineering nature unless the plans, specifications and estimates have been prepared and the construction supervised by a registered structural engineer with qualifications appertaining to such work; provided that nothing in this section of the act shall apply to such public work if the estimated cost for the completion of the same does not exceed two thousand dollars.

28. Any person entitled to be registered under this act who shall neglect or omit to be so registered shall not be entitled to the benefits and protection thereof while such neglect or omission shall continue.

29. No provisions of this act having to do with penalties and restrictions shall be operative until one year after the passing of the same.

The American Association of Engineers has issued the following bulletin: "Attention is directed to Senate bill 2507, providing for a department of public health in the United States government. The bill authorizes a secretary of public health; a first assistant secretary, who shall be 'a man trained in medical science and eminent as an authority on public health and sanitation problems; a second assistant secretary, who shall be a man expert in the science of vital statistics and public health; and a third assistant secretary, who shall be a woman trained in the science of medicine or nursing and of public health.' Without entering into the discussion of the necessity and desirability of a department of public health, it seems necessary that such a department should be provided with an engineer trained and experienced in sanitary engineering. The problems of sanitary work are less medical than engineering. The American Association of Engineers, in pursuance of its policy to give attention to legislation affecting engineers, is conferring with prominent sanitary engineers of the country in regard to the bill's lack of provision for sanitary engineering services."

ROADS OF BRITISH COLUMBIA*

BRITISH COLUMBIA has approximately 14,600 miles of road open for traffic in the unorganized districts—namely, outside of incorporated municipalities. These roads have been constructed and are now maintained at the sole expense of the Crown. About 5,000 miles of the highways may be classified as main trunk roads, subject to a heavy mixed traffic of motor-trucks, touring-cars, ore-wagons, lumber-wagons, and the more ordinary traffic of farming communities. There are also about 5,000 miles of second-class road, which carry less volume of traffic, but which normally have to support the very heavy loads connected with mining, logging and other industries. The remaining roads are generally merely roads of access, subject to little traffic, and which, though costly to construct, especially in the mountainous or heavily timbered sections, are generally fairly cheap to maintain. In addition to the roads proper —that is, roads for ordinary wheeled vehicles—there are over 8,000 miles of trail, many of which in course of time will be widened out and improved, so as to form finally a part of the highway system.

Sixty Miles of Bridges

In connection with the provincial highways there are nearly 60 miles of bridges, of which nearly 3 miles are steel structures, built either purely for highway purposes, or built as composite highway and railway bridges, in association with one of the several railway companies. At least 13 miles of British Columbia's bridges are timbered truss spans, the remainder being timber trestles.

The provincial government has also installed and maintained 48 ferries, of which the majority provide a free service. There are also 3 subsidized steamboat services plying periodically on the interior lakes.

Within organized areas the provincial government has given material assistance to the various rural municipalities in connection with the construction of the trunk roads, and particularly in connection with the laying of improved surfaces. The formulation of a definite policy for dealing with work of this nature is under consideration by the administration.

Within the five years preceding 1919, the provincial government, by contribution or direct expenditure, has applied a sum of at least $600,000 towards such work, which, among other existing benefits, is represented by about 40 miles of paved surface within municipal areas.

The province of British Columbia embraces an area of 388,263 sq. miles, or, in other words, is practically as large as France, Spain, Portugal and the Netherlands. Of this area, less than ½ of 1% is organized into municipalities; while of the total population (approximately 400,000) only 14% is resident in the unorganized areas.

Extensive Banks of Gravel

Generally speaking, the rocks found in British Columbia are unsuitable for the construction of water-bound broken-stone roads, but as a compensation there are in the majority of sections extensive banks of gravel which provide suitable material for water-bound gravel roads, or, by selection, excellent material for concrete or other hard surface. The cost of special surfacing, except on the most heavily travelled ways in the neighborhood of towns, is, of course, prohibitive, but careful experiments are being made of surface treatment of ordinary gravel roads, and in many other directions, with the object of determining upon a form of construction suitable to each locality, and which, taking the first cost, maintenance charges and quality of surface into account, will be very greatly superior to the class of road which has so far been built in the outlying districts.

The public works department, which is responsible for the highways of the province, is thoroughly alive to the necessity of further extending the highway system for the benefit, not merely of the province, but of Canada as a whole. The necessity of intercommunication by road with

*From Handbook of British Columbia, published (1919) by the Legislative Assembly, Victoria, B.C.

the rest of Canada and with the United States has given definite form to the plans. A very thorough inquiry is being made to determine beyond dispute as to what—from every point of view—will be the best route for a trans-provincial highway, as far as it affects British Columbia.

There is a highway leading from Alberni, at the head of the Alberni canal, Vancouver island, down through Nanaimo to Victoria; thence by steamer to Vancouver; then south across the Fraser river and up the left bank of this river to Hope. Improvements to this road have been carried out from time to time, and there does not remain a great deal of work to be done to make this section a thoroughly first-class highway. At Hope it becomes necessary to cross the coast range of mountains by one of three routes—either up the canyon of the Fraser river to Kamloops; up the Coquihalla valley and down the Coldwater to Merritt, and thence to Kamloops; or up the Silver creek valley and down the Roche river to Princeton.

Some Prominent Highways

The Silver creek route to Princeton, and its continuation, would be an excellent highway, but one which will require a considerable amount of work to complete. From Princeton to Cascade via Fairview, Greenwood and Grand Forks is a good road, and the construction of approximately 30 miles of road from Cascade to Rossland was decided upon early this year. At this time a fairly good road was being used from Rossland to Nelson. From the latter point a ferry-steamer is taken to Kootenay Landing, and from Creston the remainder of the highway leading through Cranbrook, Waldo, and Fernie to Crowsnest is completed and will not be a difficult matter to improve.

With regard to the other roads of the province, there is a heavily travelled road leading in a northerly direction from Ashcroft, through Clinton and Soda creek, to Quesnel. From there the road to Fort George will require to be located and built, as the old route is not desirable. Within a very short time it would be possible to complete the road leading west from Fort George along the Nechako river to Fort Fraser; thence up the Endako river to Burnt creek, and then down the Bulkley river to Hazelton.

The provincial government has also a road leading from Waldo, near Fernie, up the Kootenay river to Columbia lake, and thence along the Columbia river to Golden.

Banff-Windermere Road

There is another projected highway known as the Banff-Windermere road, which is destined to link up the east Kootenays with western Alberta. The route of this highway commences at Sinclair, on the Kootenay river valley road north of Windermere, proceeds along Sinclair creek to the Kootenay river valley; thence along the Vermilion river to the Vermilion pass (elevation 4 662 ft.) at the Alberta boundary. Of this road about 23 miles was constructed between the years 1912 and 1914, leaving about 48 miles to complete. Early in 1919 the uncompleted section was taken over by the Dominion government, who entered into an agreement with the British Columbia government to complete the road before the expiration of 4 years. This projected highway is situated midst magnificent mountain and valley scenery, a large area of which is being reserved for park purposes, and will eventually afford access to the Banff national park in Alberta.

Some idea of the magnitude of the work carried out upon this highway system may be given by stating that for the ten years preceding 1919, the expenditure upon extension, improvement and repair to the roads, trails and bridges in British Columbia has been nearly $3,000,000 annually.

It is anticipated that the Lethbridge southeastern irrigation project embracing some 350,000 acres, of which the two big natural reservoirs, known as the Milk River reservoir and the Raymond reservoir form a part, will cost between $3,000,000 and $4,000,000. H. B. Muckleston is now preparing estimates.

Letters to the Editor

DRIFTING SAND FILTRATION IN TORONTO

Sir,—For a variety of reasons the writer is particularly interested in Mr. Howard's paper on drifting sand filtration in Toronto, published in the October 2nd issue of *The Canadian Engineer*. In the first place the process is a radical departure from long established practices in water purification; and, second, the drifting sand filter plant at Toronto has ever been enveloped in a fog of uncertainty respecting its cost of operation and practical performances.

In the winter of 1913-14 the writer was preparing a monograph for the American Water Works Association entitled, "Present-Day Water Filtration Practice," and learning of the probable decision on the part of the Toronto authorities to adopt the ver Mehr drifting sand system in the proposed 60,000,000-gal. (Imperial) extension to the existing slow sand system at that place, sought to obtain reliable information about it, that he might refer to it in his then forthcoming article on water filtration matters in general. He learned that Sir Alexander Binnie was alleged to be an advocate of the process, and as the time was short before his article went to press, he cabled Sir Alexander for a statement regarding it. Sir Alexander replied that the only plant of this type he had seen was a small installation in Wales, but that he was impressed by it and thought highly of its possibilities. Correspondence with certain public officials in Toronto, and even personal inquiry on the ground, developed only the same line of indefinite information.

Prior to May, 1913, a test plant having a daily capacity of 500,000 Imperial gallons was installed by the ver Mehr company near the old West Toronto pumping station, and on May 21st, 1913, turned over to the city authorities for official test. The results of this test were reported on by George G. Nasmith and F. Adams, of the Department of Public Health, Toronto, in an article which appeared in *The Canadian Engineer* for April 8th, 1915. This test was run between the dates of May 21st, 1913, and June 27th, 1913, and upon the results then obtained, and the recommendations of Dr. Nasmith, the ver Mehr company was permitted to put in a bid for the 60,000,000-gal. installation. Of the four bids tendered, the ver Mehr bid was $1,096,000 as against the other three of $1,177,000, $1,197,000 and $1,750,000 respectively, and the contract went to the low bidder

From the time the test plant was installed in May, 1913, until the present day the writer has endeavored to obtain information relative to the cost of operation and maintenance of the new filtration works, but his efforts have thus far been without definite result. The 1915 article by Dr. Nasmith was scrutinized in vain for light on this important point, and it is with regret that even at this late date Mr. Howard seems unable to give the profession any information on this vital phase of the matter. In reply to a question by Col. Longley, he sweepingly dismisses the subject with the reply that "there are no figures available as to cost of operation." Personally the writer does not see how any discussion of the merits of the drifting sand filter can be of definite utility until some one is ambitious enough to relate the whole story and advise the public, not what this plant cost to build as compared with what either a slow sand or the established type of rapid sand system might have cost, even going so far as to grant that all three would produce an equally satisfactory effluent, but what are the actual costs of operation and maintenance.

A somewhat mysterious phase in operating results was described by Mr. Howard at the last annual meeting of the New England Water Works Association. In reply to a question by Mr. Caird relative to whether alum passes the filter, Mr. Howard states that "there is a slight trace of aluminum hydrate in the filtered water." He further said:—

"We experimented by passing the filtered water through

very fine filter papers and found that the hydrate was not decreased in any way."

Now this is suggestive. All water filtration men know that where aluminum hydrate is in suspension in water, that hydrate, no matter how finely divided the particles may be, can be removed by passage through fine filter paper; that is, if the texture is fine enough and there are enough thicknesses of the paper. If the resulting filtrate then reacts alum, the presence of undecomposed alum is proved, and not aluminum hydrate. All this suggests that as a sequence of a practically negligible period of coagulation in this process, undecomposed alum may be passing the filters, later perhaps to become decomposed and form an undesirable deposit in the pipes, or to cloud the filtered water as it leaves the taps in the city. If not so decomposed, an active corrosive agent is thus present in the filter effluent. This point requires clearing up by Mr. Howard.

From the information before him, the writer is not prepared to accept without question the Toronto drifting sand filter as a reliably efficient and economical process of water purification.

It is ingenious, and seems to satisfy the Toronto authorities; but it is not apparent that the citizens of Toronto desire the drifting sand process at any cost, and it seems quite unusual that a plant which has been operated as long as has this one, should not have developed accurate costs, a statement of which the profession at large, and the taxpayers of Toronto assuredly, would appear to be justly entitled to.

When these figures are published, it is to be hoped that they will be so decisive as to set at rest, once and for all, the doubt now existing in the minds of a great many water works engineers respecting whether Toronto is actually receiving acceptable water purification service at reasonable cost.

Colonel, Utilities Division,
Construction Division of the
United States Army

Washington, D.C., November 25th, 1919.

RECOVERY OF VALUABLE CONSTITUENTS OF GARBAGE

Sir,—The writer has read with much interest the article on various methods of garbage disposal by Samuel A. Greeley which appeared in last week's issue of your paper, and while agreeing with him on many of his points, yet his article leaves a rather one-sided impression on the mind of a layman, and as councils are oft-times made up of laymen and as Mr. Greeley has hinted at various methods of garbage disposal, such as feeding to hogs, sorting and reduction, it may be well to ask Mr. Greeley if he will be good enough, to write another article, giving some information, which he must be in possession of, such as spreading of disease amongst cattle and hogs by feeding them on garbage.

No doubt Mr. Greeley knows of many cases where epidemics have broken out among swine and cattle as a direct result of some one trying to make a few dollars by taking what is admitted to be the most filthy and unsanitary stuff and attempting to turn it into pork, beef, or anything else intended for human consumption.

If Mr. Greeley has not heard of any such cases as referred to, perhaps he will not mind writing to Kitchener, Ont., or to the Ontario Board of Health, Toronto.

Mr. Greeley also refers to the system of sorting, such as is done in "Buffalo, Rochester, Pittsburgh, Columbus and elsewhere," and admits that the revenue derived from the sale of such sorted material "does not usually much more than pay for the cost of operation."

But, Mr. Editor, is the dollar the most important item? Very few people have any desire even to poke their nose inside of a reduction plant of any kind, much less work in it. Take, for instance, the plant just outside of Detroit. Everybody who has travelled in the neighborhood of that plant can bear testimony to the very rich odors arising therefrom, even without going within a mile of the plant; and, sir, what right has any one for the sake of making a few dollars, to ask men and women to work under such conditions as must obtain, around any reduction plant, no matter what kind or where situated.

The ordinary refuse coming from a number of houses daily is of the most filthy kind, and contains many things that are indescribable. The writer has studied the question of garbage disposal for some years, and has reached just one conclusion: Burn it up, either in the open or in an incinerator, and do this just as soon as possible after the garbage leaves the house, as it only takes a few hours to produce maggots, flies and odors, all of which tend to make things unpleasant for any person handling house refuse.

Here are a few of the kind of goods the writer has seen brought to an incinerator practically every day in the year: Dead cats and dogs; decayed fish, poultry and all kinds of meat; filthy rags, which have often been used for bandages on all kind of sores; rotten vegetables, fruits and canned goods; and other filth not decent to mention. If any person does not believe this, he can prove it for himself by going into an incinerator or reduction plant—not for a few minutes, but staying there for a few hours—and the writer is convinced that once a person has done that, he will be of the opinion that incineration is the only sane, sanitary, sure way of dealing with garbage with the least possible chance of spreading disease and the greatest security for a healthy, sanitary and clean town or city.

J. G. PICKARD,
President, Canadian Incinerator
& Furnace Co., Ltd.

Toronto, December 1st, 1919.

The Engineer's Library

"COST KEEPING AND CONSTRUCTION ACCOUNTING"

By G. Ed. Ross, associate member of the Northwest Society of Highway Engineers, and assistant secretary, chief accountant and cost keeper of the Phez Co., Salem, Oregon; 172 pp. and cover, 5½ by 8¼ ins., cloth bound; price $2.50 net, post paid.

After a detailed review of the author's experiences, and testimonials to his system of cost accounting, there follow 42 pages of descriptive features which were used very satisfactorily, says the author, by the Oregon State Highway Department, of which he was formerly secretary and auditor. Pages 76 to 129 are devoted to illustrations and explanations of forms recommended. A chapter on organization follows, with a suggested organization chart. The volume concludes with a discussion of the value of good cost records and the field for competent cost accountants.

The author says: "I spent 12 years doing in large organizations what I have written about, and my book is an outline of what has been actually accomplished rather than a theoretical story of what ought to be done. It is a practical book from cover to cover, and sets forth a principle which is being used on many of the larger projects on the Pacific coast, as well as by some manufacturing firms and a great number of counties. I have attempted to handle the subject in as readable and interesting a manner as a technical subject of such a nature would warrant, and have woven into the narrative a little poetry and some statements of a general nature to get away from the dryness which frequently is found in such publications."

British Engineering Standards Association.—Thirteenth report of work accomplished, covering period from August 1st, 1917, to March 31st, 1919; 124 pages and paper cover, 5½ by 8½ ins.; published by the association at its office, 28 Victoria St., Westminster, S.W.1, Eng.

PLANNING AND DEVELOPMENT OF CITIES IN ONTARIO*

By Thomas Adams
Town Planning Adviser to the Dominion Cabinet

THE present Planning and Development Act of Ontario deals largely with planning as a matter of fixing the location and dealing with the widening, extension. and relocation of highways and parkways. Its proper description should be a highway or street planning and development act. It does not deal with town planning on the broad lines of other town planning acts which have to do with the regulation of the use of land and the character of building development in cities, towns and rural areas.

The general object of an act should be to secure proper sanitary conditions, the economic use of land and amenity and convenience in connection with the laying out and development of land. Thus the first things to get are proper sanitary conditions, which include the consideration in advance of the facilities needed to supply land and buildings with economical means of drainage, sewerage, water supply, etc.

Under the question of amenity, which may be interpreted as agreeableness of surroundings, there would be comprised the prescribing of space about buildings and the character of buildings and their surroundings.

Conditions Influencing Highway Traffic

Under convenience, the main consideration is that of highways and streets, and particularly the provision of wider main thoroughfares. It is impossible, however, to deal with this question of convenience in relation to traffic without considering at the same time the height, density, setback and use of the buildings served by the streets or highways.

You can neither plan a street or highway system as if it were a separate thing from the building development of the city, nor unless you have previously taken into consideration the zoning of the city into factory, residential and other districts.

We cannot strain the word amenity too far. What I mean is that we cannot interfere to any great extent with vested interests in property merely to obtain an agreeable or picturesque effect. If, however, the industries of a city or district depend for their success on certain restrictions on private interests in property, we should not consider it unreasonable to make these restrictions. The only things that are beyond question in connection with the restriction of private interest in property for the public welfare are the things that relate to health.

We should move at certain minimum standards in regard to what are proper sanitary conditions in respect of air space around buildings. Having arrived at those minimum standards, we say they should be insisted upon by law and that no compensation should be payable, even if our insistence upon them means that there is a loss of capital or revenue to the owner of the land.

Proper Sanitary Conditions Essential

This distinction between things that interfere with the health and welfare of the community and the things that are merely necessary for convenience and beauty is recognized in all laws relating to compensation under British and American constitutions. It is recognized in all town planning laws, and because it permits so much to be done by way of regulating the use of the land without payment by the community for compensation to private interests, it makes it of additional importance that town planning schemes should have for one of their main objects the securing of proper sanitary conditions, amenity and air space.

The provisions of the Ontario act may be briefly described as follows:—

To enable cities to have some control over the land outside their boundaries, the act sets up a new area called the "urban zone." The area of this zone comprises the land within five miles of a city boundary on all sides, or within three miles of a town or village boundary. The act recognizes the subordination of a town or village to a city, or of a village to a town.

The objection to this feature of the act is the power it gives to one municipality to have jurisdiction within the area of another municipality without having first provided the means to permit the planning of the zone to be carried out by the municipality in direct control of the area, or by co-operation between the adjacent municipalities.

Scope of Powers Restricted

The act gives a city, town or village, power to prepare a general plan, but sets forth that such plan shall deal with the restricted purposes of highways. parkways, boulevards, parks, playgrounds and other public improvements. The plan is not required to show or deal with the relationship of the highways to the character, density, height and use of buildings on the abutting lots, nor is there any provision in the scheme for preparing a preliminary and tentative plan and submitting same to the board so that their approval can be obtained in advance of incurring the expense of getting a certified plan, making the subdivision conform to the general plan.

It is difficult to see what really important object is attained by such a plan that could not be obtained by means of by-laws, or at least that does not merely consist in getting streets properly connected. The fact that the scheme does not touch buildings and sanitary conditions means that the planning of the size and form of lots is of little utility. They may be planned for the wrong purpose even if it is the purpose most agreeable at the moment of planning to the city and the owner.

Not until the city or town is planned in regard to its building development and until the location and densities of its factory and residential areas are thought out, can any highway or lot planning be settled in a satisfactory manner.

Section 9 permits the control of the planning of streets on adjacent subdivisions, so that they will be treated as one and fit in with each other. This is useful if it were part of a comprehensive scheme of town planning.

Non-Elected Town Planning Commissions

The act also permits of the setting up of a town planning commission. This commission must be a body corporate and exercise all the powers under the act. Thus, we may create an undemocratic body to override in certain respects not only the municipality that creates it, but the municipalities within the urban zone which have had no part in creating it. Hamilton has hesitated to appoint such a commission because it would give power of administration to a non-elected body with no direct responsibility to the tax-payers. If Hamilton objects to creating a commission of its own selection to deal with the planning of its highways, how much more should the municipalities within five miles, but outside of Hamilton, object to a non-elected body having control of the planning of their subdivisions and highways.

In Ontario we need an act that will really be a planning and development act, and that will show greater recognition of the value of self-government.

It is, of course, essential that adjacent municipalities—whether cities, towns or townships—be made to co-operate in controlling the development of the suburban area that rings in our cities and towns. It may be necessary that the cities be given the power to plan these suburban areas, but they should only be permitted to exercise that power after it is demonstrated that the municipalities outside the boundaries are unwilling to exercise it themselves.

It is contended that the existing planning and development act does not meet the needs of cities such as Hamilton, London and Windsor, which have been giving consideration to the desirability of preparing comprehensive town plans. These cities want a great deal more than the power to control the subdivision of land in the zones lying within five miles of their boundaries. The value of this power to them is shown by the fact that they have taken no steps to give it

*Address delivered last week at the Southwestern Ontario Town Planning Conference.

effect. What these cities require may be summarized as follows:—

1. The present act should be modified so as to permit the municipalities in the urban zones, which lie outside of the cities and towns, to prepare their own schemes if they wish to do so, while retaining the power to the city or town to include the outside area in their scheme in the event of lack of co-operation of the outside authority to prepare its own scheme or a joint scheme.

2. A special official with town planning qualifications should be appointed under the act to assist the Railway and Municipal Board to administer the act and to advise local authorities.

3. Provision should be made requiring each municipal council to make a survey of its area and conditions, and provide for assistance being given by the Provincial government in the preparation of topographical maps of all districts which are in course of development.

4. Provision should be made for securing co-operation between municipal councils and owners of land so as to give permanent effect to restrictions on the use of land relating to such matters as building lines and use and character of buildings.

5. The following powers should be granted under the act to municipalities:—

(a) The suspension of any powers in the municipal act, subject to approval of the Railway and Municipal Board, so far as the suspension is necessary for the proper execution of any scheme.

(b) Power to remove or demolish buildings which may be erected in contravention of the provisions of a scheme, after the scheme has been approved, as well as after proper notice is given and while the scheme is being prepared.

(c) Provision, not only for paying compensation for injury to owners of property, but also for obtaining for the city half of the increased value given to any property by reason of benefits accruing to such property by the scheme.

(d) Power to prescribe certain areas to be used for dwelling houses, apartment houses, factories, warehouses, shops or stores, etc., and to fix the height and character of the buildings in these areas.

(e) Exemption for any city or town from claims for compensation in respect of any requirement of the scheme which restricts the use of land for the definite purpose of health of the inhabitants or the amenity of the district, e.g. in regard to fixing factory, business or residential areas, the space about buildings, the percentage of lots that can be covered with buildings, or in regard to the height, character and use of buildings so far as such exemption may be regarded as reasonable by the Railway and Municipal Board.

(f) Power to compulsorily acquire land the same way as under the housing act of the province, without cumbersome process of arbitration; and to acquire land in excess of the amount needed to widen a street or construct a new street through a developed area, and to re-sell such land after the improvement is made.

(g) Power to fix building lines and reserve land on unbuilt-upon areas for new main thoroughfares.

(h) Power to classify any land to be used for different kinds of agriculture, horticulture, open spaces, etc., and to recommend a special system of assessment in relation to such classification of uses.

(i) Power to prevent noxious trades, bill-boards, etc., where injurious to the surroundings.

(j) Power to rectify or alter any existing subdivisions, including the pooling of lands of several owners, and the roads and streets abutting or adjacent thereto; and to initiate the planning of the subdivision of land in advance of its being placed on sale for building purposes, for the purpose of bringing owners of adjacent lands into line with any comprehensive scheme.

(k) Power to prevent building on low-lying and unsanitary lands pending reclamation and until provided with sanitary arrangements at the expense of the owners.

(l) Power to obtain proper representation of the municipal councils on town planning commissions and limitation of spending power of commissions to the cost of preparing schemes. Expenditure on execution of schemes to be subject to approval of municipal councils.

(m) Power to classify roads or streets (after zoning into factory, business and residential districts) as follows:—

(1) Main arterial roads.

(2) Secondary roads, being roads for general or local traffic.

(3) Industrial roads for access to industrial districts.

(4) Residential roads, being roads used primarily for access to residences.

(5) Parkways or boulevards, being roads which serve the purpose of either a main or secondary road, a portion of which is dedicated for ornamental purposes, etc.

The Provincial government should be asked to incorporate provisions in the present act or to frame a new act to cover these requirements; and so framed as to permit local authorities to prepare comprehensive schemes of town planning.

ZONING CITIES FOR TO-MORROW*

By W. J. Donald
Secretary, Chamber of Commerce, Niagara Falls, N.Y.

THE zoning or districting of towns and cities is, to my mind not only an integral part of town planning but even the fundamental basis on which all town planning must rest. This becomes apparent when one defines zoning as the determination of the character and intensity of the use to which lands within any given area are to be put. To be sure, zoning has been carried on in Canadian and American cities with little or no reference to town planning, and town planning has frequently been attempted without detailed consideration of the purposes to which the area is to be put.

In order to preface further discussion by securing a clear understanding of what zoning actually is, it seems wise to explain in detail what one city, Niagara Falls, N.Y., proposes to do. One of the first projects undertaken after the preparation of the final city plan, was the adoption of a zoning scheme. Note that a city plan had been prepared or at least almost completed first. The zoning map which was prepared, frankly recognized the plan, and the use to which lands may be put in Niagara Falls will keep in mind the general plan. This zoning plan provides for different uses for different sections of the city, and for varying degrees of intensity of use in different sections. After all, city planning is fundamentally a recognition of the fact that there must be differentiation between different sections of a city.

The Niagara Falls plan provides for six classes of zones or districts, for which different conditions of use, height and area of buildings are provided.

1. Residence districts for single family dwellings only, occupying an area of not over 30% of the lot, not more than 45 ft. high, and with side lots of 10 ft.

2. Residence districts devoted to residence purposes including two-family and group houses for not more than ten families, occupying an area not over 50% of the lot, not over 45 ft. high, and with side lots of 10 ft.

3. Apartment house districts, devoted to apartment houses and "tenements," with a height not exceeding the width of the street on which they face.

4. Commercial districts devoted to retail and wholesale trade, and incidental industry, requiring not more than five employees.

5. Industrial districts in which so-called "light" industry, not emitting undesirable noise, fumes or smoke, are permitted.

6. Unrestricted districts in which any industry, however disagreeable or dangerous, may locate.

In any of these classes of districts, uses permitted in a more restricted district are allowed. For each class of district, there are refinements as to use, area and height of buildings which we need not discuss here, but which in the

*Address delivered last week at the Southwestern Ontario Town Planning Conference.

practical application of the proposed zoning ordinance, occasion a great deal of discussion and call for a great deal of careful consideration and careful and patient explanation and educational work.

The word "zoning" is doubtless somewhat misleading. I have already observed that in Canada some people think of it as some sort of procedure for controlling the growth of the environs of growing cities. I wish its application might be extended to cover such a purpose in American cities, but I think that more progress is likely to be made in that direction in Canada than in the United States. This use of the word originated in Germany, where districting efforts gradually assumed the character of zones, the care of which often proved to be the area within the original walled town. A glance at any zoning map in the United States would give little indication of "zoning" in the German sense, but our "zones" are merely districts varying widely in area and location.

Despite the effort of professional city planners to popularize the more accurate word "districting," the people where districting work has been carried on persist in using the word "zoning," so let the people rule. "Zoning" it shall be.

Dependence of Zoning on City Planning

It is worth recalling that the Niagara Falls zoning ordinance was prepared as an integral part of a city plan for Niagara Fals. Unfortunately, this is not true of all other cities. I do not believe that it is true of any Canadian city, with the possible exception of Halifax, or of most American cities. You will be interested to know, I am sure, that in America, Nova Scotia was first to provide for the districting of towns and cities—as early as 1904. In 1909, Los Angeles passed an ordinance controlling the use of lands, making the ordinance retroactive. That ordinance has been declared constitutional, not only by the Supreme Court of California, but also by the Supreme Court of the United States, as a proper exercise of the police power. Of course, many municipalities had long ago created fire and building districts in the interests of public safety, but the extension of districting to include health and general welfare has been of this recent origin.

When Berkeley, Cal., adopted an ordinance in 1913, it provided for an optional districting plan. The ordinance provided for a large number of residence districts and permitted the citizens to petition for restrictions. An Ontario law for cities of over 100,000 provides for the establishment of residence districts on petition from which apartments, industries, etc., are excluded. More recent state laws and city ordinances provide for the zoning of the whole town or city.

Now, it is evident that petition ordinances and laws, such as exist in Ontario, do not anticipate any ordered planning of a city. Districting done under such laws is purely spontaneous, undirected and sporadic. It may be actually unwise and undesirable, as experience in Berkeley has actually proven. Home-owning petitioners seem prone to ask too little for the protection of their neighborhoods, though some have been known to ask too much. The difficulty in both cases is that the petitions were not based on a considered and sound interpretation of town planning fundamentals.

Topographical Knowledge is Basic

Basic in any town-planning work is a knowledge of the topographical background on the basis of which the main lines of transportation are likely to be determined. The availability of water transportation is very likely to determine the location of industry, especially heavy industry. Industry seems to naturally seek low-lying lands and waterfronts. Residences seek higher and dry areas. Topographical conditions are certain to affect the direction of prevailing winds by which smoke and fumes are carried. Mountains and hills, lakes and rivers are likely to determine, in part, the location of parks and public recreation grounds. All of these factors, especially the location of railroads and industry, affect very definitely the use to which lands are likely to be put.

It is scarcely necessary to argue, therefore, that zoning is an integral part of city planning, and that if zoning does not happen to grow out of town planning, the preparation for zoning should be so intensive as to relate the work to every other phase of city building and particularly those phases which are affected directly by topographical features.

Zoning as Basis of Intensive Town Planning

But there are many phases of town planning that are of secondary importance and very dependent upon the character and intensity of the use to which lands are to be put. If we could tell in advance just how all the land in and about Hamilton will be used 5, 10 or 25 years hence, how much easier it would be to plan properly for parks and open spaces, school grounds and play grounds, sewers and water and gas mains, arterial streets and parkways, quiet residence streets, street car lines and industrial switching tracks and belt lines, as well as public buildings.

Presuming that having once determined on the main principles of a plan for the city, based on topographical and other natural conditions, it is possible to determine also with reasonable certainty, the likely economical use of all lands in the city, let us consider in detail a few advantages to be gained.

Consider for a moment the interrelation of all these uses. Having once determined the proper general location for heavy industries, it is then possible to plan for adequate water terminals and, possibly, industrial canals; for railway sidings, terminals and belt lines; for street ways properly paved and wide enough for heavy, slow-moving trucks; for sewers designed to carry off the refuse of industry; for water mains possibly carrying raw rather than filtered water.

Industrial Houses

But modern industry, despite so many labor-saving devices, still calls for labor. Industrial housing areas should be reasonably close to the industrial areas, so that workmen may walk to work, yet far enough away and in such direction that the evils of "nuisance" industry may be minimized. Residence sections determine the location, number and even character of schools and their grounds. Schools in industrial housing areas should most certainly be planned as community centres, and there is an especial need for adequate playground space surrounding them. Incidentally, it would be an excellent improvement if some sort of park might be interposed between industrial housing areas and the nearby industries where employment is found.

Streets

In turn, to preface the planning of streets by zoning the city, will result in important economies. Most cities have shown little or no discretion in the planning of streets. The humble owner of a home in a section largely occupied by working men must pay for pavement on a street as wide as that used by his motor-driving employer. It is a question whether streets in industrial housing areas should be paved at all. Indeed, it has been suggested that there should be no public traffic ways in front of working men's houses, but merely pathways for pedestrians and play space for children, while traffic to the street should be served only by a paved alley for delivery purposes.

Lots and Blocks

Along with uniformity of street widths and street improvement should go uniformity of the depth of lots and size of blocks. Industry frequently is handicapped by the smallness of blocks. Sometimes, they get round the difficulty by securing the privilege of blocking or closing streets which should be left open. In fairness to both, industry and the public interest should not come into conflict in such a fashion. The conflict should be anticipated by zoning. Industry has a right to know where it can expand economically without coming into conflict with public opinion or public rights.

Workmen in turn should not be required to buy lots that are unnecessarily deep and viciously narrow. Lots that are too deep represent an unnecessary expense to the indus-

trial wage-earner. Moreover, they are a constant invitation to the building of rear houses, another vice for which the working man pays, if not with cash, at least with life and blood.

Transportation

The intensity of the use to which land is put has a particular bearing on the question of the daily movement of the population, without going into questions of technique on the control of the area and height of buildings, or the legal questions involved; we may consider the significance of this question, as it affects the requirements of a city, especially transportation.

I believe it is the custom of every city outside of New York to crave a distinguishing skyscraper. As a matter of fact, New York investors in skyscrapers have long since become disillusioned, as the average high building in New York brings a return of about 2%. The first skyscraper pays excellently for a time—its offices are light and airy and highly desirable, but once flanked by others, the returns soon reach the unprofitable level. Excessively intensive use of land has actually proven uneconomical to the property owners responsible.

Intensive use of land is moreover a liability to the community. Lower Manhattan could not empty itself into its own streets. Intensive use of building lots should call for correspondingly wide streets. Europe does not build towers of Babel such as one finds in New York, and such as other cities imitate. Intensive use calls for a corresponding provision of land for open space—of land for streets on which pedestrian, wheeled and car traffic may be accommodated. It is especially related, therefore, to the provision of street car service.

As a matter of fact, zoning in New York City grew out of the evident necessity for limiting the heights of buildings. The Heights of Buildings Commission soon discovered that it would be necessary to discriminate between sections of the city in any effort to regulate heights. A zoning commission was the logical consequence. Limitations on the intensity of use have therefore a very direct bearing on other city planning problems. In particular, the limitations on the possibility of providing transportation demand limitations on the use of land.

Enough has been said to indicate that the zoning of a city—that is, the determination of the character and intensity of its use—has a very definite bearing on every phase of city planning.

Does Zoning Pay?

I think I ought to add that zoning is one of the fundamentals of city planning which, fortunately, costs nothing except the costs of administration. I believe, too, that by permitting a careful anticipation of the city's future needs, it saves the city thousands of dollars that would otherwise be wasted. If time were available, I should like to discuss how zoning protects and stabilizes property values, how it protects the property owner against depreciation and the refusal to renew loans, how it protects the moneylender who loans on property, and how in general it protects the valuation on which the city bases its taxes.

W. A. McLean, Deputy Minister of Highways for Ontario, in an address to the Electric Club, Toronto, gave an outline of the present highway situation in Ontario. The need of the province in this connection is, he said, for a system of highways with continuous maintenance which would be reasonably passable. Ontario might well, he thought, increase its expenditure on good roads, but, on the other hand, economy must be practised, and roads built in proportion to the traffic which they accommodate. Close to large cities, where there is a heavy concentration of traffic, construction must be heavy in proportion, while similar construction in rural districts would not be justified. It would be out of the question to adopt one type of roadway throughout the province. There are, he said, 142,000 miles of highway in Ontario, and a large proportion of this mileage is surfaced road.

ETHICAL AND PRACTICAL SIDES OF TOWN PLANNING*

By Noulan Cauchon
Consulting Engineer and Town Planner, Ottawa

THE basic idea in town planning is the ethical side of the question; that is, man's right to live and the necessity for the survival of the race. One cannot recall too frequently Ruskin's great saying that "there is no wealth but life."

The fulfilment of this principle is accomplished through the technique of economics, such as controlling transportation, width of streets, height of buildings, the area of lots which may be covered, and the cubical contents of the rooms and buildings thereon. These are all but means toward the end of securing sunlight and air and the other conditions which are indispensable to health and amenity; and in the final analysis to secure the highest efficiency in the unit of manpower and consequently the maximum of production.

This is the justification for town planning as understood to-day. The artistic side of it evolves as the truthful expression of the purpose in view.

90% of City Buildings Doomed

As is frequently reiterated, a city no more than an individual can live unto itself. It depends upon its environment for the nature of its development; that is why in our planning there should be no hard and fast line separating urban and rural conditions; the one should blend into the other; they are complementary to each other.

You should plan broadly and largely, and with vision to the measure of your faith in the future of the country, as that is the basic power sustaining the development of the city. While your plans should be exhaustive, they should only be carried out as your progress and needs warrant. You should not only plan the future extensions of your city towards the country, but you should also replan your existing city.

I believe that in twenty-five or thirty years, practically 90% of all the buildings existing in our Canadian cities will have disappeared and been replaced by others more suitable to the purpose. The buildings will have disappeared from one of three causes:—

First, a number of them will have fallen down.

Second, a number will have been burned down.

Third, others will have been torn down by reason of the development of the city demanding new construction to meet the economic necessity of greater earning power to carry the charges on the increased values of the land.

The problems of Hamilton are the problems of every other city and town in Ontario to the degree of their population and development, and what Hamilton is to be congratulated upon is the manner in which it has fearlessly tackled these problems and is seeking their solution.

Railway Problem Comes First

The first thing which must be tackled is the solution of the railway problem, which is a special one on its own merits in every locality, due to physical and other conditions. I have had the privilege of making, in collaboration with W. F. Tye, of Montreal, a report on the railway situation in Hamilton. This report was accepted unanimously by the city council of Hamilton, who are still fighting for its accomplishment. Subsequently I made a report to the Hamilton Plan Commission on the general development of the city, resting upon the economic conditions of the surrounding country.

The whole of Eastern Canada from Quebec westerly to about Brandon, Man., is absolutely dependent upon the United States for its supply of coal, and should that fail, or to the extent that it may fail, must our railways, our industries and even our home fires slacken to a point unpleasant to contemplate. The moral to be drawn from that is that we must develop our potential water power to lessen as much as possible in certain directions our dependence upon coal. But we

---

*Address delivered last week at the Southwestern Ontario Town Planning Conference.

must be very careful in the development of that water-power that the capital cost of it must not approach the cost of development of steam power, or little will have been gained.

The trend of rural population in Canada from 1872 almost to date has continually increased towards the city, thus lessening the production from agriculture and increasing the cost of living. This has been my reason for advocating the settlement of returned soldiers and others upon lands around the cities and towns, where they may be induced to take up agricultural pursuits under intensive cultivation, the whilst enjoying the amenities of civilized life, good roads, doctors, churches, schools, and the greater efficiency which they and their families can thereby attain.

This principle and its application in Ontario and Quebec, with the further crop insurance and aid of irrigation, has been recommended for thorough investigation by the parliamentary committee which recently sat at Ottawa to consider Soldiers' Civil Re-establishment, and I trust that the proposal for the diversion of the Grand River towards Toronto, Hamilton and the Niagara Peninsula, will shortly be taken up for investigation. The map of the country just referred to, showing the proposed metropolitan district and the numerous towns within it, emphasizes the necessity of not only planning the individual towns, but also the relationship which there is between them from a transportation and a sanitary point of view.

[NOTE.—At this point Mr. Cauchon's formal address ended and he began to show slides, discussing each in informal manner. The following, therefore, is a general outline report, not verbatim, of the remainder of his speech.—EDITOR.]

Plans were shown of the proposed railway re-organization in the city of Hamilton, and the advantages of the uptown station were set forth. In this connection, Mr. Cauchon pointed out that the new by-law being submitted to the city of Hamilton for the Guelph and Galt Hydro Radial, seemed to assume that the station would be at Stuart street, in conjunction with the present Grand Trunk station at that point. The "Hydro" have accepted the common entrance of the Tye-Cauchon plan, but have not yet declared themselves upon the uptown station.

Attention was drawn to the newspaper rumors that the "Hydro" might require or expropriate the Dominion Power & Transmission Company's radials centering in Hamilton. In view of the acknowledged convenience of the uptown feature, both as regards the T.H. & B. station and the radial terminal, Mr. Cauchon asked what would happen if the latter were purchased by the "Hydro." Would they maintain two terminals, one at Stuart street where passengers would have to get off and pay an extra fare uptown, and maintain the present radial terminal, or would they attempt to abandon it and bring all the radials into the Stuart street station? He advised the citizens of Hamilton to see to it that they obtain the uptown station for both steam and radials.

Views were shown illustrating the proposed developments for Hamilton, including a view of the turning tracks in the New York Central station as demonstrating that the proposal for Hamilton was quite feasible and good in operation.

Railway Problems in Various Cities

Views of Ottawa were shown, illustrating the railway conditions there and the fact that trains come from the main line of the Grand Trunk 4,000 ft. to the Central Station and back out again,—a thousand feet greater each way than what is proposed for Hamilton, and lacking a greater facility that Hamilton will have in being able to operate its trains around the curve and out again instead of backing in and out.

Referring again to Hamilton, illustrations were shown of the proposed Mountain Road development in its economic and also its scenic advantages, the proposed widening of Ferguson Ave. from the station to the base of the Mountain Park, and the development of the old quarry into a stadium for sports. Under this plan 3% grades for haulage to the top of the mountain are secured, and a by-law is being submitted at the coming municipal election to provide for $50,000 as a beginning on these roads.

The railway problem in London, Ont., as reported upon by Mr. Cauchon, was fully illustrated and reasons given why, although the conditions were somewhat similar to Hamilton, owing to the differences in levels an elevated cross-town track seemed to him the best solution.

By way of interest, slides were shown of the plan of Delhi, India, which is an elaboration of diagonal streets; and a plan of Paris, showing Haussmann's work in the replanning of that city.

To illustrate the proper treatment of the relation of buildings to scenery in regard to public institutions on the Mountain brow, such as the new hospital, Mr. Cauchon showed views of Durham Cathedral, the Walls of Carcasonne in Southern France, the Alhambra of Granada, the Acropolis of Athens, a terrace at Amalfi in Southern Italy, and the great Dufferin Terrace at Quebec.

Niagara-to-Windsor Highway

Views of the proposed mountain-side highway from Niagara to Hamilton were shown, and the point emphasized that if a great highway were carried through Southwestern Ontario from Niagara to Windsor, it would form part of a great transcontinental highway from New York to Chicago. The evidence that this is the proper route for attracting American travel to Canada, he said, is that it is the speedway of the Michigan Central and American freight through Canada, by reason of its shortness.

Mr. Cauchon concluded his address by showing some views of Niagara Falls, N.Y., where the railways are acutely congested, and explained the solution which he had submitted at the request of the Chamber of Commerce. The keynote of this plan is the lowering of the crossing of the Niagara gorge by about thirty feet, enabling grade separation and better railway approach to the bridge on both the American and the Canadian sides, which, he said, would permanently relieve the congestion at the border.

GARDEN CITY'S LOW INFANT DEATH RATE*

FIFTEEN years ago a group of reformers built a new town on garden city principles, 34 miles from London, to prove, among other things, that a union of town and country life was possible and practicable, and that as a result there would be healthy children and the rate of infant mortality would be reduced.

The time of proof has come. "It is an interesting fact to record," says the Garden Cities and Town Planning Magazine, "that during the eventful and difficult year of 1918, the infant mortality rate in Letchworth was 30 per thousand births. This is the lowest figure it has ever reached (in 1917 it was 36) and is by no means due to a low birth rate."

A garden city is not a mere residential community. Herein it differs from the garden suburb. It is intended to be "a small town, organized for modern industry, of a size that makes possible a full measure of social life, surrounded by a permanent belt of rural land." It does not aim to be a bigger, but rather a better town, where the normal activities of life shall have the best chance of expression.

Dr. Helen MacMurchy recently stated that every year in Ontario nearly 10,000 children under the age of five go to their graves. A recent bulletin of the Toronto Bureau of Municipal Research states that during the last decade, through the activities of the Department of Public Health, the infant mortality of Toronto has been reduced from 182 per thousand in 1909 to 103 in 1918. The general rate for the whole of Canada was recently given as 140 per thousand; for Great Britain, 139; for Sweden, 96; for Norway, 86; for New Zealand, 76.

Considering the many factors that contribute to the destruction of child life, the fact that only 30 children out of every thousand failed to survive at Letchworth, during the year 1918, cannot fail to carry conviction of the soundness of town-planning principles to any fair-minded observer.

*From Conservation.

TOWN PLANNING CONFERENCE AT HAMILTON

ABOUT 150 delegates (from municipalities, boards of trade and other organizations) to the third annual town planning conference of southwestern Ontario, assembled last Thursday and Friday at Hamilton, Ont.

Proceedings commenced on Thursday morning with the registration of delegates, and a meeting of the executive for the purpose of striking committees.

At the noon luncheon, Dr. Horace L. Brittain, Bureau of Municipal Research, Toronto, gave an address on "Citizen Co-operation and Government." Owing to the vaccination requirements enforced at the international boundary, Lawrence Veiller, secretary, National Housing Association, New York City, who was expected to speak, was unable to attend, and Thomas Adams, town planning adviser, Ottawa, spoke in his place, taking as his theme, "The Housing Situation from an International Standpoint."

Mr. Adams stated that the housing question was essentially international, for in every country there was a shortage of houses, and men were finding difficulty in obtaining places of abode. The question had become very acute during the war in the U.S.A., and the government had found it necessary to build houses for workmen employed in shipbuilding, munition plants, etc. Specialists had been sent to Great Britain to study the question, with the view to building permanent dwellings.

Millions Spent in United States

Under the auspices of the Housing Corporation, Department of Labor, controlled by Mr. Eidlitz, New York, $60,000,000 had been allotted to the United States Shipping Corporation, and $100,000,000 to the Labor Department to finance housing schemes, which had been started in all parts of the United States—in Philadelphia, Wilmington, Norfolk, Charleston, Portland, etc.

In his opinion, said Mr. Adams, the scheme which had obtained the best result in the creation of a garden suburb, was that at a village outside Camden, N.J.

The housing scheme had been started by the federal government under pressure, owing to war conditions, and unfortunately that same spirit of doing things only under compulsion still predominated, with the result that although $100,000,000 had been expended on good houses, congress had decreed that no more houses were to be built.

Contrasting conditions in Canada with those in the U.S.A., Thomas Adams declared that Canada had no housing policy during the war, but was now able to commence a policy of reconstruction without adopting extravagant housing schemes.

The housing policy in the Dominion is the result of co-operation between federal and provincial governments, and soon after the armistice, provincial governments were called into conference at Ottawa in order to draft legislation for good housing.

The federal government decided to loan $25,000,000, and an Order-in-Council of February 20th, 1919, gave the conditions of the loan, and recommended:—

Conditions of Federal Loan

1. That a provincial scheme of housing be prepared.
2. That a house should not cost more than (a) $3,500 when built of timber or brick veneer, and (b) $4,500 when built of brick, stone, or concrete.
3. That the period of loan be (a) 20 years, (b) 30 years.

That loan be made to housing associations having a dividend paying less than 6% to its shareholders, and to individuals owning lots.

The order further states that the loan should be made to assist returned soldiers; and is not applicable to anybody having an income exceeding $3,000 a year. Conditions are laid down specifying the minimum size of rooms, external light and air, and sanitary arrangements.

Legislation had been passed in all provinces to deal with the housing scheme, but it was futile to pass legislation and not carry it into effect with good administration. Ontario had made the most progress, and had appointed a Director of Housing, J. A. Ellis, responsible for the carrying out of the scheme, and Mr. Ellis had an architect and a town planner to assist him. A large number of municipalities were taking advantage of the scheme, and had spoken for the full amount of money available.

Ottawa was cited as having the best scheme in Canada, and Mr. Adams described how 22 acres of land had been purchased at $3,000 an acre, and divided into 168 lots. Streets were planned to suit traffic requirements, a high spot selected as a clubhouse, 1½ acres devoted to children's play-ground, 1 acre to a bowling green, and 1 acre as a public space for recreation. Each purchaser of a lot paid towards this arrangement, which was so satisfactory that every lot was sold in a short time.

To Counteract Social Unrest

Private enterprises, said Thomas Adams, never attempted to solve housing problems. The best way to counteract social unrest was to house people well, and this could best be done by effective town planning. The chief weakness in a municipality was its peak in expenditure, because no attempt had been made to apply business principles to the government of a city. Money spent on local improvements and developing land by proper planning, would help to keep down wasteful expenditures. Wasted pavements, sewers, and water mains in front of vacant lots, should be made revenue-producing by building houses upon these properties. Money spent on constructive municipal work, in building houses, developing a city on some lines, was justified even if it meant an increase in taxes. The peak should be kept down by directing expenditure along productive channels.

The speakers at the afternoon session were S. Baker, city clerk, London, whose address was on "Municipal Government and Reconstruction," Sir John Willison, and J. A. Ellis.

Sir John Willison said the best council a city could have was one in which every element was represented, including labor, women and capitalists, viz., a council which maintained a close co-operation with public life. Good government was a matter of good citizenship, and an educative body should be created, and an endeavor made to inculcate duties of citizenship in public and secondary schools. He did not think that the reason given by some citizens, that many good men refused to serve their city because of the criticism or treatment given public men by the press, was a true one. As a rule, the men most successful in private affairs made the best public representatives on account of their training and business experience.

Ninety-seven Municipalities Adopt Housing

J. A. Ellis told of the work of his department in connection with the Housing Act. The housing scheme, said Mr. Ellis, was a matter of reconstruction, and a very important matter for all municipalities.

Ninety-seven municipalities had adopted housing, 70 municipalities were now building, and 93 proposed building next year. All cities, with the exception of three, one of which was now passing a by-law, and all towns, had taken advantage of the scheme. Next spring, it was anticipated, 5,000 houses would be built. A stage had now been reached, where a number of houses had been built in many municipalities, and the public were able to see the kind of house they may expect to obtain. Efforts had always been made to have municipalities follow the best lines to obtain the best houses with the best results.

Two items were both cheap and common, namely, sunlight and fresh air. The bureau had aimed at obtaining reasonably sized rooms, proper windows, a reasonable amount of land round the house, with the house so placed as to obtain the maximum of fresh air and sunlight, and good sanitary conditions. The result had been that 95% of the houses built, were absolutely satisfactory and first class in every way.

Mr. Ellis stated that some weeks ago he went over 80 houses. The total amount of taxes, insurance and payments ranged for $26 to $32 a month. Houses of a similar class were rented at $35 to $40 a month, which proved that houses

could be bought cheaper under the housing scheme, than if they were rented.

He was strongly in favor of the scheme, as it encouraged thrift, and allowed families to be brought up in good sanitary homes, and he hoped that private houses built in the future will follow the plans and ideals of municipally-built houses under the housing scheme.

Several delegates took part in the ensuing discussion, J. P. Geoffrey, Galt, maintaining that the provincial fund would soon be exhausted, and not meet the situation during the next five or six years. He maintained that the only solution was the duplication in Ontario of the building and loan system in operation in Philadelphia, where there are 160 building associations.

He declared that recreation grounds and play-grounds were essential for contented young manhood, and said that 10% of the land in Galt is devoted to parks and playgrounds.

Thomas Adams expressed his satisfaction that it had been possible to obtain a special act allowing a city to manage itself as it wishes. Some of the causes of dissatisfaction in civic government were the numerous spending bodies. He considered it democratic that citizens should elect a council, who would in turn elected their own mayor, and favored a continuity of government, giving as an example, 18 aldermen in office for three years, six retiring each year. This system would assist in eliminating commissions, would centralize administrative power in one body, and give executive power to the city officials, who should draw salaries commensurate with their responsibilities.

Advocates Civic Research Bureaux

Dr. Brittain was invited by the chairman to make proposals as to action by the conference in general in carrying out suggestions made in his address earlier in the afternoon. Dr. Brittain suggested that cities of over 30,000, establish local bureaux, and co-operate with the Dominion Bureau of Research. By so doing, the Dominion bureau could retain the services of specialists such as engineers and auditors, who would visit the civic bureaux when required, and give expert advice.

Speaking at the evening session to a representative gathering of citizens, civic officials, members of the Board of Trade, and delegates, J. A. Ellis maintained that every municipality should have the right to govern itself, and shoul any municipality have a plan or scheme requiring legislation to make it effective, his personal opinion was that such legislation should be given. No government would refuse a popular demand, but it was essential to know definitely what was wanted.

The two addresses of the evening were given by Thomas Adams, town planning expert, and Noulan Cauchon, consulting engineer, Ottawa. Both addresses are printed in full upon other pages of this issue.

Will Interview Ontario Cabinet

FoHowing Mr. Adams' address, delegates from London, the Border cities, Brantford and Chatham, expressed their approval of the suggestions made in the address, and the meeting, by a unanimous standing vote, supported Mr. Coppley's resolution: "That this conference approves of the town planning scheme, and resolves that the chairman appoint a deputation representative of all municipalities to see the government with reference to the new legislation, and amendments as suggested by Thomas Adams."

Friday morning's session commenced with reading of the reports of the honorary and corresponding secretaries, and the consideration of resolutions recommended by the executive committee. The following is an extract from the report of the corresponding secretary:—

"The last town planning conference of southwestern Ontario was held in October, 1916. Remarkable developments have taken place since then along many lines, but provincial town planning has not developed with the times. Standing to-day and looking back three years since last we met, we see with a clearer vision than before the great need and the great importance of planning our cities, towns and rural communities, but we seem to be no nearer the accomplishment of our ends than at the last convention. Notwithstanding appearances, however, much foundation work has been accomplished during the last three years, and many towns have appointed town planning boards. I believe we are are now on the eve of greater accomplishments.

New Legislation Needed

"Lack of adequate legislation has also interfered seriously with local town planning progress. The Planning and Development Act of 1918, while a recognition of the importance of planning highways, urban zoning, organization of town planning boards, etc., has been found defective. When we came to apply the act in Hamilton, the city council was alarmed at the wide-open door to large expenditures, and refused to appoint a commission under the act.

"The Hamilton council refused to proceed under the act, and they were justified in their course of action. The Hamilton town planning board is not appointed under the act because the taxpayers are not sufficiently safeguarded, and consequently the board's hands are tied and we are in a large measure marking time. The town planning board in Hamilton is simply a committee of the council, without sufficient appropriation to carry on its work.

Object of Conference

"One object of this conference is eo educate the public and the municipal councils along town planning lines, to create public sentiment and bring it to bear upon the provincial parliament. We cannot magnify the importance of town planning too much, and in order to accomplish our ends we need the help of the women of this convention.

"Each municipality has its own peculiar problems, but in order to solve them, a comprehensive city or town plan should be secured, adopted, approved by a provincial board and registered. In Hamilton we are after such a city plan, which shall co-ordinate various very ambitious individual projects in the course of development. For example:—

"1. The harbor board is working on a vast harbor scheme preparing for a future seaboard town.

"2. The housing commission is building scores of up-to-date dwellings for workingmen, having all the conveniences.

"3. The parks board have hundreds of potential acres to develop for future generations.

"4. New railway plans have been projected by Messrs. Tye and Cauchon; these have been adopted by the city council, and stand ready to be worked out.

"5. Several millions of dollars have been voted as collateral security in connection with Hydro-radial lines, terminals, freight yards, etc.

"6. A highway commission has been appointed to lay out roadways which shall make Hamilton the hub of southwestern Ontario.

"7. A proposition is now before the city council, having in view the beautifying of the Mountain Face park, which is five miles long, and a most unique natural asset belonging to the city, which is awaiting development.

"There are narrow streets to widen, boulevards to build, slum conditions on the outskirts of the city to clean up, factory, commercial and residential districts to restrict. A city plan is absolutely necessary to remedy defects and to facilitate improvements, and yet up to date so many hindrances obstruct the forward movement that apparently we are no nearer attainment of a city plan than three years ago, when we met at our last convention.

Considerable discussion took place during the consideration of the resolutions, and the objection was raised that the conference was attempting to cover too wide a scope of municipal affairs.

A resolution was passed urging the department of education to provide for the education of children in the duties of citizenship. The convention also endorsed a suggestion that fire chiefs be instructed to address school children in fire prevention.

It was resolved that the town planning convention considers it imperative that no factories emitting smoke and noxious fumes be allowed to locate on the side of the municipality from which the prevailing wind blows, and demands the adoption of a by-law preventing the improper location of such factories.

A letter from the London Trades and Labor Council, asking that the conference use its efforts to have the housing commission's regulations made easier, and that provision be made for cheaper houses, provoked much argument, and it was decided to forward the letter without comment to the federal and provincial housing commission.

The speakers at the luncheon were: W. J. Donald, secretary, Chamber of Commerce, Niagara Falls, N.Y., whose address is published in full upon another page of this issue, Louis Black Duff, Welland, and Thomas Adams, who spoke on "Town Planning—Does it Pay?"

In the course of his speech, Mr. Adams said that the first thing to be considered in town planning was transportation, as the railways and waterways were with us and could not be moved. Having planned those, the next problem was the zoning of the city, dividing it into factory, business, and residential districts, but just as much respect should always be paid to agricultural developments outside, as to manufacturing elements inside a city. The Niagara peninsula should be considered as a whole in transportation and zoning questions. He maintained that there was absolutely no necessity to have subways or tunnels to carry traffic in Canada, provided the principles of town planning were carried out.

The first thing to be done was a survey of existing conditions with a view to obtaining data, and these facts, with their relation to each other should be considered by practical men. Science and practical experience should work side by side. It costs nothing to zone a city except the expenditure in preparing a scheme and its administration.

The conference was brought to a close at the afternoon session by papers on "Looking Ahead," by Mrs. Dunnington Grubb, landscape architect, Toronto, Mayor McBride, M.P.P., Brantford, and W. A. Crocket, M.P.P., Barton.

According to newspaper rumors, the Dominion government appears to be unwilling to allow the Hydro-Electric Power Commission of Ontario the privilege of constructing the proposed St. Lawrence canalization and power development. It is said that the government considers that the proposed work should be a federal undertaking.

Excavation work is well advanced for the extension which the Steel Company of Canada, Limited, are making to their bolt and nut building. This extension will provide an additional floor space of 60,600 sq. ft. The extra accommodation will be used partly for storage and shipping and partly to enlarge the facilities for the various manufacturing processes. The estimated cost of the work is $200,000. The new building will be four stories high, of reinforced concrete construction. F. G. Peden, of Montreal, is the architect, and the Anglin-Norcross Co., Ltd., of Montreal, have the general contract.

Three-quarters of a million dollars have been spent by the Administrative Commission of Montreal, during the present year, on permanent street works and repairs, according to a report given out by the Department of Public Works. A total of $519,903.43 has been spent on new paving. The following amounts have been expended on repairs: Street paving, $97,157.82; street crossings, $32,490.86; permanent sidewalks, $25,878.05; temporary sidewalks, $21,501.74; water-bound macadam, $64,022.04; levelling unpaved street, $13,842.26; oiling streets, $27,612.99; and repairs to bridges and tunnels, $11,904.44.

In an address to the members of the Peterboro Board of Trade, Thos. Adams, town planning adviser of the Dominion government, spoke of the housing problem and said that any town that offers bonuses to manufacturers shows signs of weakness. He said: "We have not solved the problem of social organization of industry. The present condition means strikes, slumps, disorganization, even among well-paid workers, a growing burden of taxation, rapidly increasing because we have no well-defined organization to plan our cities, as we do our industries. City planning has to do with transportation, streets, waterways and buildings. No streets should be less than 66 ft. wide. In the residential district 40 ft. is ample, but in the congested districts they should be 100 ft. wide."

CONCRETING IN COLD WEATHER

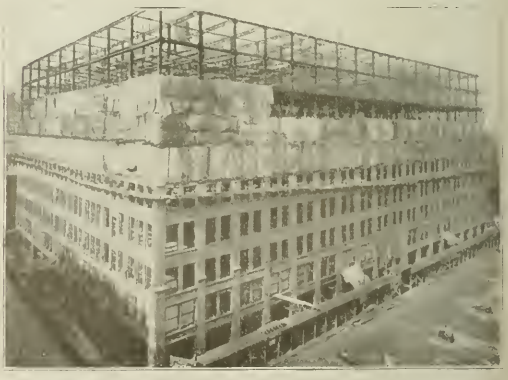
IN the October 23rd issue of *The Canadian Engineer*, there was published an article by A. E. Wells, of Chicago, president of Wells Bros. Construction Co. of Canada, Ltd., on the advantages that accrue to owners of buildings as a result of continuing concrete work during cold weather.

"Primarily the reason why building has been inactive in winter," says Mr. Wells, "is that concrete does not harden so rapidly when its temperature hovers near freezing. But

RAND, MCNALLY & CO.'S PUBLISHING PLANT

we heat our homes, offices and stores, and coal is a comparatively small operating cost. We are to-day able to enclose a structure, warm it with simple coke stoves, heat aggregates prior to mixing with Portland cement, and keep the concrete or mortar warm until hardening has occurred."

A few days ago Mr. Wells kindly mailed to *The Canadian Engineer* the two accompanying views showing how his firm has enclosed with tarpaulins the floors of buildings



REGINA WAREHOUSE, ROBERT SIMPSON CO., LTD.

upon which they desired to do concrete work in cold weather. The Regina warehouse of the Robert Simpson Co., Ltd., is entirely a reinforced concrete structure. The Rand, McNally & Co. publishing plant is a steel building with concrete floors and fireproofing.

J. B. Nicholson, Ltd., contractors, of Hamilton, Ont., are moving their head office to the Excelsior Life Bldg., Toronto, and are establishing a concrete-products plant at Toronto, although they intend to retain their present office and plant at Hamilton. The firm is specializing in the design and construction of circular reinforced concrete bins for coal, grain and oil storage.

INVESTIGATION OF CONCRETE-PROPORTIONING

TWO weeks ago eight engineers from various parts of the United States and Canada held what may prove to be one of the most important meetings in the history of concrete. Called as a special session of two sub-committees of the American Society for Testing Materials' concrete committee, this meeting is of historic interest in the engineering world in that it constituted the first definite co-operative step toward taking the proportioning of concrete materials out of the realm of the empirical and into the limits of science and certainty.

At the last annual meeting of the American Society for Testing Materials, Sanford E. Thompson, chairman of the committee on concrete and concrete aggregates, stated that there is no more important subject in civil engineering to-day than the finding of proper methods for proportioning concrete, and he intimated that it was high time that the guesswork be eliminated from plain and reinforced concrete construction. He argued that there is now a sufficient abundance of accurate data from independent sources to enable the committee to establish certain fundamental principles, the lack of which has hitherto caused most of the general fog surrounding the simplest problems in concrete proportioning, and he urged the society to take some definite steps along this path.

Largely as a result of Mr. Thompson's plea, the members of the concrete committee decided to try to establish whatever basic truths there may be underlying Prof. Abrams' fineness modulus and water-cement ratio theories and Mr. Edwards' surface area theory. Both of these gentlemen were expected to attend the Chicago conference, which was held at the Lewis Institute, November 17th and 18th, and Prof. Abrams was there, but unfortunately Mr. Edwards was snow-bound in Dakota while returning from an inspection of a bridge for the United States Bureau of Public Roads. The arguments and data on behalf of the surface area method were ably defended, however, by H. F. Gonnerman, first assistant to Prof. A. N. Talbot of the University of Illinois; A. T. Goldbeck, engineer of tests, U.S. Bureau of Public Roads; and Roderick B. Young, of the engineering laboratories, Hydro-Electric Power Commission of Ontario.

The Bureau of Standards, which has taken a prominent part in the various discussions that have centered around the fineness modulus and surface area methods, was represented by J. C. Pearson. The chairman of the meeting was Cloyd M. Chapman, engineer of tests, Westinghouse, Church, Kerr & Co., Inc., who has taken a very active interest in both methods, and whose laboratory has conducted a considerable number of tests. The other sub-committee members present were P. J. Freeman, of the Pittsburgh Testing Laboratories, and Prof. M. O. Withey, of the University of Wisconsin.

Every one of the eight above-mentioned engineers have at their disposal the most modern laboratory facilities for concrete research and tests, and are in the best possible position for accomplishing some really revolutionary results by co-operative effort,—joint interpretation of pooled experience.

As a result of the two-day conference, it was decided that these eight and several other outstanding laboratories should join hands in the carrying out of a definite program of tests which was formulated at the conference, and the results of which will very likely throw considerable light upon some of the points now disputed by the advocates of one or the other methods of proportioning, and may also demonstrate that the fineness modulus and surface area theories are not so diametrically opposed as their sponsors still appear to believe. At least one investigator, Roderick B. Young, of the Hydro-Electric Power Commission of Ontario, believes that these methods are in harmony on all essential points. He brought out some interesting evidence to support his belief in a valuable article, "Analysis of Concrete-Proportioning Theories," which was published in last week's issue of *The Canadian Engineer*. Mr. Young summed up very concisely the outstanding points of both methods, and showed how the Hydro-Electric Power Commission's tests substantiate both the surface area and water-cement ratio theories.

The present schedule of co-operative tests has been designed to cover all points in dispute and includes the use of stone, gravel and slag and various combinations of these three materials, so that the laws formulated may be entirely general.

REPORT OF J. C. T. O. STATUS COMMITTEE

SEVERAL months ago the Joint Committee of Technical Organizations appointed a status committee, with H. G. Acres, hydraulic engineer of the Hydro-Electric Power Commission of Ontario, as chairman. This committee has just presented its report, which is published in full in this issue. It recommends legislation based upon somewhat different lines than the bill which was recently drafted by a special committee of the Engineering Institute of Canada and which was intended to serve as model legislation to be introduced into the various provincial legislatures.

It is claimed that the basic difference between the J. C. T. O. and E. I. C. bills is that the former is popular legislation and the latter class legislation. As proof of the fact that the J. C. T. O. bill is popular legislation, it is pointed out that it is applicable to any profession or even trade if so found desirable.

The E. I. C. is said to have attempted to legalize the definition of engineer, whereas the J. C. T. O. bill gives wide authority to duly constituted boards to say who is and who is not an engineer, without requiring those passed as engineers to fit any prescribed definition. In other words, under the J. C. T. O. bill an electrical engineer, for example, would be an electrical engineer merely because he was recognized as such by the board of governors of the electrical

engineering profession in his province, and he would not be entitled to practise as an electrical engineer until he was so recognized.

The J. C. T. O. bill may have decided advantages as compared with the E. I. C. bill and it should receive the careful attention and close study of all members of the Engineering Institute of Canada. If, upon discussion, it appears to present better chances of being adopted by the provincial legislatures, and if it is fair to all engineers and fulfils the need for protection through legislation, then it is the bill that is wanted and the E. I. C. should not hesitate to support it in lieu of their own draft. The report has been forwarded by the J. C. T. O. to the officials of the various technical organizations represented on the J. C. T. O., and should now be discussed by the members of those organizations.

In his letter of transmissal accompanying the report, Mr. Acres says:—

"This report has been prepared at the cost of a considerable amount of discussion and research, and is the result of a number of meetings of the committee which were held from time to time throughout the past summer and early autumn. Owing to the season it was, of course, very difficult to get the members of the committee together, and in stating that the bulk of the committee work was done by Messrs. Hynes, McEvoy, Chipman and Le May, which is a fact, there is no hint of reproach, as I know personally that most, if not all, of the other members of the committee were out of town for practically the whole of the period above mentioned.

"Whatever value this report may have in the estimation of those for whom it has been prepared, it has been the result of the active and sympathetic interest taken in the matter by the gentlemen above named, and the thanks of the Joint Committee of Technical Organizations is due them in full measure."

It will be observed by those who read the proposed bill, that Part Two is an ancillary act covering only structural engineers. The committee's idea is that Parts Three, Four, Five, etc., would be other ancillary acts exactly the same as Part Two excepting that Part Three could cover architects; Part Four, electrical engineers; Part Five, mining engineers; etc. An ancillary act would be passed for each profession in which the majority of members petitioned for registration; also for those professions in regard to which the minister of education might deem registration to be in the public interest.

The Status Committee does not appear to lay claim to any credit for originating the legislation which it advocates, as it is explained that the whole has been patterned largely upon legislation now in force in some parts of the United States.

It is understood, moreover, that the conclusions arrived at by the Status Committee as a whole do not necessarily represent the opinions of all of the individual members of the committee, but have merely been put forward in order to pave the way for discussion of controversial points upon which an agreeement must be reached before any united stand can be taken by the various technical organizations interested in the proposed legislation.

PERSONALS

Walter Sidney Harvey, who resigned last week from the engineering staff of the Toronto Harbor Commission in order to accept a position with Alexander Potter, consulting engineer, New York City, was born December 16th, 1880, at Swansea, Wales. Mr. Harvey was educated at St. Andrew's College, Swansea, and at the Swansea Technical College, and was then articled for three years to T. J. Scoones, consulting engineer, of Bristol and London. After completing his term as articled pupil, Mr. Harvey remained with Mr. Scoones for a further 2½ years as assistant engineer on the design and superintendence of construction of the following works: Gravity water system at Cheddar, Somerset; sea defence works at Barry, Wales; dry dock reconstruction at Bristol; and coaling station at St. Vincent, Cape Verde Islands, West Africa. From 1904-7 Mr. Harvey served as contractor's engineer for the British Insulated & Helsby Cables, Ltd., in charge of track work and street paving in connection with the Chesterfield electric tramways. Upon completion of this work he remained for a time with the Chesterfield corporation as chief assistant to the borough engineer in carrying out some double-tracking, road widening and sewer construction. He resigned from this position in order to become contractor's engineer for Robt. H. B. Neal, Ltd., in charge of the construction of sewerage works and pumping station at Weston-super-Mare, and of the widening of the William Wright dock at Hull. In November, 1910, Mr. Harvey came to Canada and joined the staff of the main drainage department, city of Toronto, on the design of storm sewers and interceptors. Six months later he went to Lethbridge, Alta., as assistant city engineer, subsequently becoming city engineer. In March, 1914, Mr. Harvey returned to the department of works, Toronto, as designing engineer of the sewer section. He resigned in May, 1918, to accept the position of construction engineer for the Leaside Munitions Co., Ltd., and was engaged in the construction of a 12-in. shell plant for the United States government. Although this plant was practically completed, it was not operated owing to the signing of the armistice. Last January Mr. Harvey completed all outstanding work for the Leaside Munitions Co., Ltd., and joined the engineering staff of the Toronto Harbor Commission as engineer of sewer design, and was engaged under the direction of Geo. T. Clark, designing engineer, in the preparation of schemes for storm and sanitary drainage for the water front development, and of designs for outlet extensions to the city's overflow sewers. Mr. Harvey's first work on Mr. Potter's staff will be at Warren, Ohio, where he will investigate the relative merits of several sources of water supply, appraise the present system and prepare plans and specifications for a new system. Mr. Harvey is an associate member of the Institution of Civil Engineers of Great Britain, and was the recipient of the 1908 Telford premium awarded by that institution. He is also an associate member of the Engineering Institute of Canada and for the past year has been secretary-treasurer of the Toronto branch and secretary of several of that branch's most important committees.

J. W. Nelson, who has been a member of the Board of Control of Ottawa, Ont., for many years, has resigned in order to accept an appointment as superintendent of streets, succeeding George Little, who gave up the position owing to ill-health.

Norman M. Campbell, who has been associated with the Canadian Ingersoll-Rand Co., Ltd., for the past twenty years, has resigned his position as sales manager of that company, to take effect December 31st. He has been appointed managing-director of the General Combustion Co. of Canada, Ltd., manufacturers of industrial furnaces, with headquarters in the New Birks Bldg., Montreal.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Banff, Alta.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Wednesday, January 7th, 1920, for the construction of a bridge over the Bow River at Banff, Alta. Plans can be seen and specification obtained at the Department of Public Works, Ottawa; at the offices of the District Engineers at Edmonton, Alta.; Winnipeg, Man.; Vancouver, B.C.; Equity Building, Toronto, Ont.; Shaughnessy Building, Montreal, Que.; at the post-offices, Calgary, Alta., and Banff, Alta.

Brampton, Ont.—Peel county council is considering construction of a permanent road from Main St. to the Grand Trunk yards on Church St.

Calais, N.B.—Contract let by provincial government to the Standard Engineering Co., of Toledo, Ohio, for repairs to the St. Stephen end of the International bridge, which spans the St. Croix River. The work is in charge of Engineer Paul Pocock, of Toledo, O.

Cobourg, Ont.—A representative from the Provincial Highways Department was here recently expropriating ten feet of land on each side of William St. This will be used for part of the transprovincial highway.

Finch, Ont.—Tenders will be received until 7 o'clock p.m., January 19th, 1920, addressed to J. G. Cameron, County Road Superintendent, Finch, Ont., for the construction of certain sections of road in the United Counties of Stormont, Dundas and Glengarry. Further information can be obtained at the office of the superintendent.

Hamilton, Ont.—Special road extension committee of Wentworth county council recommended that fifty miles be added to the county's road system.

Kingston, Ont.—Frontenac county council will give $8,000 for a bridge at Sharbot Lake, providing the government undertake and build the same.

L'Assomption, Que.—Town council let contract to M. Brouillette for construction of bridge. Estimated cost, $31,000.

Levis, Que.—Municipal council will call for tenders for the construction of a new road leading to the city hall. Two tenders submitted, one for $3,365 and another for $4,750, were not accepted, as the council only voted $1,600 for the work.

London, Ont.—City Engineer H. A. Brazier recommended to the city council that the old iron bridge over the River Thames, at Ridout St., be replaced next year by a $140,000 concrete structure.

London, Ont.—City Engineer H. A. Brazier will present to No. 2 committee of the city council a program of paving to be commenced in 1920, that will add 16 miles to the city's paved streets. According to Mr. Brazier, his department has in mind the need of putting 50 miles of streets in the city in the well-paved class.

Macdonald, Man.—On December 16th a by-law to authorize the issue of debentures to the amount of $175,-528.86 for the construction of a system of gravel roads will be submitted to the ratepayers. Secretary-treasurer, H. Grills.

Meaford, Ont.—A by-law to raise $50,000 for improving the leading thoroughfare of the town will be submitted to the ratepayers at the coming municipal election. The intention is to construct a reinforced concrete pavement to connect with the new county-provincial highway at both ends of the municipality. Clerk, Geo. G. Albery.

New Westminster, B.C.—Work on the reconstruction of the approaches and the construction of a sidewalk on Westminster bridge, involving an expenditure of $21,000 for both contracts, has started. The contracts have been awarded by the Department of Railways to the Nickson Construction Co. for the trestles and to Cox and Verge for the sidewalk. Both firms are Vancouver concerns.

Niagara Falls, Ont.—The city council intends to construct an asphalt pavement with Willite process on Benson St, between Palmer Ave. and St. Clair Ave. Estimated cost, $1,975. W. J Seymour, city clerk.

Ottawa, Ont.—City council intends to pave Rideau St. City clerk, N. H. H. Lett.

Peterborough, Ont.—County council will add to present road system by extending the Block road in Otonabee easterly.

Point Grey, B.C.—Municipal council decided to proceed with the grading of the boulevards of Maple St. and East Boulevard, south of Forty-ninth Ave., and will invite tenders for the installation of the four-foot-wide cement sidewalks.

Quebec, Que.—Contract for approaches and caissons of the Batiscan bridge has been given to the Gosselin Co., of Levis, Que. This bridge will unite the Montreal-Quebec highway and the cost will be $250,000. The masonry work will cost $150,000 and the superstructure about $110,000.

WANTED

Three assistant Highway Engineers, each capable of taking charge of the Highway work in one county. Duties to commence February 1st, 1920. Applicants to state salary expected, experience, qualifications, etc. All applications to be filed with the undersigned before January 19th, 1920.

J. G. CAMERON,
County Engineer, U.C. of S.D.G.

Dated at Finch, Ontario, December 2nd, 1919. 384

Russell County, Ont.—Tenders will be received by F. A. Senecal, Co. Rd. Supt., Plantagenet, Ont., until noon, Monday, December 8 next, for the construction of about 3½ miles bituminous-bound macadam road, 16 ft. wide. Plans and specifications may be seen at the office of the county engineer, V. E. Belanger, L'Orignal, Ont.

St. John, N.B.—According to a statement made by Hon. Peter J. Veniot, Provincial Minister of Public Works, plans are now before the Federal government for the improvement of the 91-mile St. Stephen-St. John Rd., and work will likely start next year.

Sarnia, Ont.—City council may construct a sidewalk on Ross Ave.

Sarnia, Ont.—City council may submit by-law to electors to authorize purchase of municipal asphalt paving plant. City engineer, J. A. Baird.

Shuniah, Ont.—Municipal council plans construction of a roadway from the boundary of Port Arthur to the proposed mills of the Great Lakes Paper Co. Clerk, H. A. McKibbin, Port Arthur.

Smith's Falls, Ont.—At a conference of Good Roads representatives held in Carleton Place a resolution was passed, asking the county councils of Carleton and Lanark to approve the designation of a county-provincial highway from Richmond to Smith's Falls, via Prospect and Franktown. It is expected that the councils will endorse the resolution and will forward it to the legislature for its approval. It is expected that a new highway will be constructed in the near future from Brockville to Smith's Falls. Should this programme be carried out, a main county-provincial road passing through this town and connecting Brockville with the Capital will be the result.

Toronto, Ont.—A deputation of municipal officials from Ontario county waited on Hon. F. C. Biggs, Minister of Public Works, urging that the government go ahead next spring with the completion of the interprovincial highway between Oshawa and Toronto. Mr. Biggs promised consideration of their demands.

Toronto, Ont.—A committee, composed of representatives of the King Street Merchants' Association, city officials, Ontario government, harbor board, railway companies, steamship companies, board of trade and branches of the law society, will meet the Board of Control to discuss the proposed widening of York St., the establishment of a new street between Bay and York, and the extension of University Ave. from Queen to Front Sts.

Vancouver, B.C.—The Board of Works has instructed F. L. Fellowes, city engineer, to proceed with macadamizing half a dozen blocks on Sixteenth Ave. Estimated cost, $3,200.

Victoria, B.C.—City council plans repair of part of Esquimalt Rd. City engineer, F. M. Preston.

Victoria, B.C.—City Engineer F. M. Preston reported to city council that it will cost $5,000 to resurface Esquimalt Rd. and $15,000 to resurface and regrade it.

Welland, Ont.—Contract let by Welland county council to B. G. Begy, St. Catharines, for construction of pavements in Bertie Tp. Cost, $18,000.

Wiarton, Ont.—Town council plans paving work to cost $8,000. Engineer, E. D. Bolton, Listowel, Ont.

Windsor, Ont.—City council let contract to H. Bondy, 321 Sandwich St. West, for sidewalks costing $23,000.

Windsor, Ont.—Under the leadership of Gustav L. Lindenthal, engineer, of New York, a movement is on foot to organize a corporation under the charter of the American and Canadian governments for the purpose of constructing a $28,000,000 expansion bridge across the Detroit River connecting Detroit and Windsor.

Winnipeg, Man.—Ratepayers passed by-law to provide for erection of new bridge over the Assiniboine River at Maryland St. City engineer, W. P. Brereton.

Winnipeg, Man.—Approximately $1,000,000 of debenture issues for road improvements will be voted on at the forthcoming rural municipal elections at Dauphin, Westbourne, Sifton, St. Andrews, Ellice, Birtle, Macdonald, Albert, Springfield and Gilbert Plains. Provincial highway commissioner, A. McGillivray.

York Township, Ont.—Township council gave third reading to a by-law to extend Woodville Ave., westerly to Don Mills Rd.

WATER, SEWAGE AND REFUSE

Brantford, Ont.—Plans are under way for the reconstruction of the waterworks system. Ratepayers will likely be asked to vote five or six hundred thousand dollars for this purpose. The work will be done sectionally. City engineer, T. H. Jones.

Chatham, Ont.—At a public meeting, called on November 28th by the city council for discussion of the three water schemes before Chatham, Engineer Proctor, of the E. A. James Co., Ltd., Toronto, explained his report, which recommends the adoption of the Lake Erie project at a cost of $600,000, as compared with $300,000 that would be required for the Thames scheme. After the public meeting the commissioners passed a resolution, recommending the Lake Erie plan to the citizens, and asking the city council to prepare a by-law to submit in January.

Drumheller, Alta.—In our issue of November 6th an item was published under above heading stating that water main extensions were planned by municipality at a cost of $5,000. We are now informed that this amount is additional to work already under way. This town voted $16,000 for water main extensions about last May or June and later in the season decided they would require this further $5,000 worth, or $21,000 in all. The work has been carried on under Hadden and Miles, Ltd., consulting engineers, Calgary, and the larger portion of it is completed. It has now been closed down for the winter and will be finished in spring.

Goderich, Ont.—An estimate of the cost of sewers on Elgin Ave. and Regent St. have been made and works committee recommended that these be the first sewers constructed in 1920. Clerk, L. L. Knox.

Halifax, N.S.—City council will construct a sewer on Decartaret St. City engineer, F. W. W. Doane.

Jenner, Alta.—An irrigation project, which will bring water to 270,000 acres in the vicinity of Jenner, has been presented to F. H. Peters, Commissioner of Irrigation for the Dominion government, who is located at Calgary.

Kingston, Ont.—City council passed by-law for the construction of sewers in Russell, Raglan, Macdonnell, Adelaide and Park Sts. City engineer, R. J. McClelland.

Levis, Que.—The Quebec Superior Board of Health have issued a new order to the city, requiring the installation of a new filtration plant. Plans must be in the hands of the board by January 1st, work started by April 15th and completed by September 15th.

Montreal, Que.—City will construct sewers on St. Zotique St. and Patricia Ave. City commissioner, R. A. Ross.

Napanee, Ont.—The town council has employed the E. A. James Co., Ltd., Toronto, to make a valuation of the assets of the Napanee Water Co., and to report upon what extension and improvements should be undertaken, providing the municipality purchases the assets of the company. The improvements will include filters, pumps and about four miles of new mains.

Peterboro, Ont.—William Kennedy, Jr., of Montreal, submitted a preliminary report to the Utilities Commission on the proposed filtration system. Estimated cost, $800,000. The commission will ask city council to have a by-law submitted to the ratepayers for its construction.

Windsor, Ont.—Engineers from the office of the E. A. James Co., Ltd., Toronto, are here reporting upon the valuation of the Windsor city waterworks system. The valuation is required by the city council in connection with the Border Cities Utilities vote, which may take place in January.

Sarnia, Ont.—City council may construct sewers on Confederation St., from Emma St. to John St.; on Nelson St., from St. Vincent to Collingwood St., and on Capel, Russell

Tarvia
Preserves Roads
Prevents Dust
Broadway, Tillsonburg, Ont., waterbound macadam treated annually with "Tarvia-B" since 1913

How Tillsonburg keeps its Streets firm, smooth and dustless—

Many towns and cities have just the same problem that Tillsonburg, Ontario, faced six years ago. They find their macadam streets do not stand up under the hard usage of modern traffic and are put to it to secure a remedy.

In 1913 Tillsonburg began using "Tarvia-B" on its main thoroughfare, shown above, which carries heavy traffic. After repeating this treatment yearly, Mr. C. H. Denton, Reeve, writes us:

> "I consider 'Tarvia-B' one of the best coverings for roads that we have ever used and have used it on Broadway for the last few years and I consider the life of the road has been saved at least to the extent of one-third, as we have had comparatively no repairs to make on it since we began using 'Tarvia-B.' And I believe that every macadamized road should have at least one coat of Tarvia every year, and if this is done I am sure that the road would last at least one-third longer."

Tarvia is the solution of the street problem for many Canadian cities and towns. Tarvia streets are free alike from dust and mud, with a tough, resilient surface that stands up well under heavy traffic, as the above photograph of Broadway shows.

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by any one interested. If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention.

and Milton Sts. Also drain on Exmouth St. City engineer, J. A. Baird.

St. Catharines, Ont.—Tenders will be called this week by City Engineer W. P. Near for sewage disposal plant.

Vulcan, Alta.—Council plans installation of a waterworks system. Estimated cost, $9,000. Reeve, E. W. Butchart.

Woodstock, Ont.—The Provincial Board of Health has given its approval to the proposed new intercepting sewer and sewage disposal scheme, and a by-law regarding it will be submitted to the people at the municipal elections the first of the year. The new plant will cost $100,000.

York Township, Ont.—Township council accepted reports of Engineer Frank Barber on construction of 6-in. water mains in Watford Ave. and East Earlsdale Ave.

York Township, Ont.—Township council let contract for the laying of water service pipes on Windermere Ave., Montye St. and Mulberry Crescent to G. Thompson, superintendent of the township waterworks.

LIGHT, HEAT AND POWER

Edmonton, Alta.—City Commissioners may have a new sub-station erected in West Edmonton next year. Estimated cost, $60,000. The extension of the lighting system in this district is also being considered.

Kitchener, Ont.—Hydro-Electric Power Commission of Ontario has asked the local Hydro Commission to consider the erection of three sub-stations in various sections of the city.

London, Ont.—An addition is to be built in 1920 to the Hydro station on Ridout and Horton Sts. at an approximate cost of $30,000. Work on the building, Engineer Buchanan stated, would probably begin in March.

Port Hope, Ont.—A convention will be held here in January of all the municipailties in the Trent Valley district to discuss plans for the purchase by the municipalities of the Trent Valley power plants and transmission lines now owned and operated by the Hydro Electric Power Commission of Ontario.

St. Boniface, Man.—City council plans improvements at power-house. Clerk, J. B. Cote.

Southampton, Ont.—Immediate action on the part of the Hydro-Electric Power Commission of Ontario will be asked by the northern municipalities interested in the proposed power development of the Saugeen River.

Winnipeg, Man.—City council let contract for steel towers for the second power transmission line to Point du Bois to the Canadian Bridge Co. for $136,163.

RAILWAYS

Bridgeburg, Ont.—The Toronto, Hamilton and Buffalo Railway Co. will construct the new line from Welland to the Canadian Niagara frontier at a point on the Niagara River, six miles below Bridgeburg, which will be the approach to the new bridge to be constructed over the Niagara by the C.P. Ry. The Canadian-Niagara Bridge Co., which will construct the new bridge, is capitalized at $8,000,000.

Calgary, Alta.—Application to electrify the C.P.R tracks constituting the spur line from Twelfth Ave. along Fifth St. East will be made by Assistant City Solicitor Marcus to the Railway Commission.

Gowganda, Ont.—Construction of a railway from Elk Lake to Gowganda planned by company headed by I. W. Soloway. Company will use 30-lb. rails and gasoline locomotives.

Guelph, Ont.—Hydro-Electric Power Commission of Ontario has offered to purchase the Guelph Radial Ry. for $150,000.

Regina, Sask.—City council granted permission for the construction by the C.P.R. of a spur track to serve the T. Eaton Co.'s warehouse.

Toronto, Ont.—City council authorized the extension of Bloor St. civic car line. Approximate cost, $200,000.

Toronto, Ont.—The plans for the construction of the Mount Pleasant car line are all prepared, and the Board of Control authorized the expenditure of $600 for printing them, and to call for specifications and tenders.

Toronto, Ont.—City council decided to submit to electors by-law to take over Toronto street railway in 1921. Also by-law to authorize issuing of $5,000,000 debentures for purchase of necessary rolling stock and building of extensions, including Mount Pleasant civic line and Bloor St. civic line extension in preparation for taking over T.S.R. in 1921.

Waterloo, Ont.—Town council decided to submit Hydro radial by-law to electors on January 1st.

FACTORIES AND LARGE BUILDINGS

Barrie, Ont.—Barrie is having a campaign to raise funds for a Y.M.C.A. building.

Belleville, Ont.—The Tivani Electric Steel Co., Belleville, proposes to erect a large new plant here.

Belleville, Ont.—Sketch plans for a ten-room public school building will be received by Arthur McGie, chairman, Sites, Buildings and Repairs, Board of Education, up to December 18th, 1919.

Bishop's Mills, Ont.—The erection of a consolidated school and a community hall are being considered.

Brandon, Man.—Extensive improvements to the public school are planned by the School Board for 1920. A by-law authorizing the raising of $150,000 for school improvements, will be submitted to the ratepayers.

Toronto, Ont.—Contract let to J. B. Nicholson, Ltd., Hamilton, for 600-ton circular reinforced concrete coal-handling plant, to be constructed for F. R. Pember, corner Jones Ave. and Grand Trunk Ry.

Toronto, Ont.—Since November 1st permits for buildings estimated to cost $1,600,000 have been issued by the City Architect's Department. The permits include $206,000 for schools, $190,000 for stores, $170,000 for garages, $236,000 for warehouses.

Toronto, Ont.—A. D. McBride has organized an Auto Service Co. for the purpose of building a fireproof parking station and storage garage on the south-west corner of Richmond and Sheppard Sts. Approximate cost of site and building, $600,000. Mr. McBride may also erect a parking and storage station building east of Yonge St. and two more stations convenient to residential districts.

Toronto, Ont.—Baldwin's, Ltd., of Swansea, England, who have taken over the plant of the British Forgings, Ltd., will commence the erection of two buildings immediately, according to Business Agent Bowering, of the Structural Iron Workers' Union. He also expects that the steel work of the Pantages and Loew's Theatres will be commenced within the next ten days.

Vancouver, B.C.—The Regal Films, Ltd., propose to erect a $500,000 theatre on Seymour St.

Vancouver, B.C.—Vancouver Gas Co. plans extension of its plant. General manager, George Kidd.

Vancouver, B.C.—Howard & Davis have taken out a permit for the construction of a $10,000 tire service station building at 1301-1303 Granville St.

Vancouver, B.C.—Officials of the Soldiers' Civil Re-establishment are preparing plans for the reconstruction of and additions to the Shaughnessy hospital.

Vancouver, B.C.—The Marconi Wireless Telegraph Co. of Canada, Montreal, will build a powerful radio depot in this vicinity. Estimated cost, $2,000,000.

Vancouver, B.C.—City council granted permission to the Regal Films Co. to build an overhead bridge across the lane between Granville and Seymour Streets, in connection with the theatre which they will erect.

Vancouver, B.C.—The Allen Theatres, Inc., who are to build a $300,000 theatre at the corner of Seymour and Georgia Sts. early next year, have applied for permission to build an arcade over the lane abutting on the rear of their site.

Vancouver, B.C.—A permit covering the construction of a new saw factory on Industrial Island has been taken out by T. H. Tait, manager of the Ætna Saw Works. Estimated cost, $4,000. The Canadian Pacific Ry. Co. has taken out a permit for alterations to the interior of the cold storage building at the foot of Gore Ave. Estimated cost, $4,000.

Walkerville, Ont.—Building permits for the present year to date total $1,808,000. In addition to this, there is building going on at the present time to the amount of about $100,000 for which permits have not been issued pending the completion of some of the plans. It is expected that the total figures for the year will reach well over $2,000,000.

West Toronto, Ont.—The General Mercer branch, G.W.V.A., plan erection of clubhouse.

Whitby, Ont.—A movement on foot here to erect a memorial hospital for Ontario county was presented to the council. Estimated cost, $25,000. Address, Major Blow.

Windsor, Ont.—The British-American Brewing Co. will erect a $125,000 extension to their plant.

Windsor, Ont.—Board of Education asked city council for an appropriation for the purchase of a school site on Tecumseh Rd.

Windsor, Ont.—Work on erection of new Allen theatre on Ouellette Ave. will start at once. Architect, C. Howard Crane, Detroit.

Windsor, Ont.—Plans have been prepared by J. P. Thomson, architect, Walkerville, Ont., for erection at Pelissier Ave. and Maiden Lane of memorial hall for Border Cities branch, G.W.V.A.

Windsor, Ont.—Excavation work has started on new departmental store to be erected by the C. H. Smith Co. on Ouellette Ave. Building will be four stories, and of structural steel, hollow tile and brick construction. Work will be under direction of R. Westcott Construction Co. Architect, A. H. McPhail, Windsor.

Winnipeg, Man.—The Elgin Gas Motor, of Elgin, Ill., is erecting a three-story factory here.

Winnipeg, Man.—A theatre, costing $600,000, will be erected here next March. Address, S. E. Richardson.

Woodstock, Ont.—Ratepayers passed by-laws granting concessions to the Brunswick Canadian Products Co. and the Warren Pipe Organ Co., who will now erect large plants here.

York Tp., Ont.—Township council plans erection of fire hall. Clerk, W. A. Clarke, 40 Jarvis St., Toronto.

MISCELLANEOUS

Brokenhead, Man.—A scheme is under way by the Dominion government for the deepening of the Brokenhead River.

Edmonton, Alta.—Tenders addressed to N. L. Harvey, Deputy Minister of Railways and Telephones, Edmonton, Alta., will be received up to 12 o'clock noon, December 10th, 1919, for the supply of the following telephone poles: Cedar poles, 30 ft. long, 7-in. top, 6,000; cedar poles, 30 ft. long, 6-in top, 6,000; cedar poles, 25 ft. long, 5-in. top, 16,000; cedar poles 25 ft. long, 5-in. top, 20,000; cedar poles, 20 ft. long, 5-in top, 76,000; tamarack poles, 25 ft. long, 5-in. top, 27,000; tamarack poles, 20 ft. long, 5-in. top, 76,000. Specifications can be obtained on application to the Engineer and Plant Superintendent's office at Edmonton.

Fort William, Ont.—It is reported that the Canadian Car and Foundry Co. has decided to build ships as one of its chief industries.

ACCEPTABLE CHRISTMAS GIFTS FOR SURVEYORS

The Principles and Practice of Surveying

By CHARLES B. BREED, Professor of Railroad Engineering, and GEORGE L. HOSMER, Associate Professor of Topographical Engineering, Massachusetts Institute of Technology.

Vol. I, ELEMENTARY SURVEYING, Fourth Edition, includes the essentials of a comprehensive knowledge of practical surveying. Now selling its 46,000th copy.

xix. + 591 pages. 5 by 7¼. 216 figures. Flexible binding, $3.50 net.

Vol. II, HIGHER SURVEYING, Second Edition, is chiefly devoted to a consideration of the various methods of conducting topographic and hydrographic surveys. This Volume has reached its 16th thousand.

xvii. + 443 pages. 5 by 7¼. 164 figures. Flexible binding, $3.00 net.

Plane Surveying

A Text-book and Pocket Manual.

Total Issue, 36,000.

By JOHN CLAYTON TRACY, C.E., Professor of Civil Engineering, Sheffield Scientific School of Yale University.

Treats with great thoroughness fundamental principles and methods, giving many practical suggestions and directions which are usually left for oral instruction.

xxvii. + 794 pages. 4 by 6¾. 604 figures, 3 folding charts. Flexible binding, $3.50 net.

Plane Surveying and Exercises in Surveying

Combined in one volume.

xli. + 962 pages. 4 by 6¾. Flexible binding, $4.00 net.

Theory and Practice of Surveying

By the late J. B. JOHNSON, C.E., Seventeenth Edition, Rewritten, Total Issue, 49,000, by LEONARD S. SMITH, C.E., Associate Professor of Topographic and Geodetic Engineering, University of Wisconsin.

Book I treats of Surveying Instruments, Book II, Surveying Methods, and Book III, Geodetic Surveying. Nine Appendices and Thirteen Tables are also included.

xxxi. + 921 pages. 5¼ by 8. 263 figures, 7 plates, Cloth, $3.50 net.

Field Engineering (*Complete*)

Eighteenth Edition, Revised and Enlarged.

Total Issue, 59,000.

By WILLIAM H. SEARLES, C.E., and HOWARD CHAPIN IVES, Professor of Railroad Engineering, Worcester Polytechnic Institute.

The American Railway Engineering Association Spiral has been added to the complete binding of this popular work, thereby increasing its value to the engineer in practice. The Searles Spiral is also retained.

657 pages. 4 by 6¾. 148 figures, 4 folding plates. Flexible binding, $4.00 net.

Your friends appreciate sensible Christmas presents. Why not give them useful books, such as these? Fill in and mail the coupon TO-DAY.

ON APPROVAL OFFER

If cash accompanies your order, we will forward copies of any of these books on ten days' approval. If they should prove unsuited to your needs we will refund your money, provided the books are returned within ten days after their receipt

USE THIS COUPON

Renouf Publishing Co.,
27 McGill College Ave., Montreal, Canada.

Gentlemen: Enclosed you will find remittance for $....., for which please send me on 10 Days' Approval the books indicated below:

Renouf Publishing Company

27 McGill College Avenue **MONTREAL, CANADA**

Galt, Ont.—New plans will be prepared by the Parks Commissioner for erection of fireproof grandstand of concrete and steel construction at Dickson Park, tenders received being too high, the lowest of which was for $29,400. while the ratepayers voted only $15,000 for the stand.

Hamilton, Ont.—City Council will submit a by-law to the ratepayers authorizing the expenditure of $5,000 for motor equipment for the fire department.

Hamilton, Ont.—The following are among the by-laws which the city council resolved to submit to the electors on January 1st: By-law for borrowing $72,000 for the purchase of fire protection appliances; $50,000, to be used in the construction of the proposed mountain highways and improvements; $850,000 for the construction of the first unit of a storm overflow sewer system; $150,000 for the establishment and construction of a civic athletic field on the Scott Park lands and for improvements to Victoria Park, North End Park, Mountain Face and Gage Park. Hydro radial by-law will also be submitted.

Ottawa, Ont.—Joint stock companies incorporated last week include the following: Fairchild Engineering Co., Ltd., Brantford, $50,000; W. H. Yates Construction Co., Ltd., Hamilton, $500,000; St. Maurice Power Co., Ltd., Montreal, $6,500,000.

Port Arthur, Ont.—By-laws will be submitted to electors in January to authorize extension of street railway at approximate cost of $102,000, extension of municipal telephone system at cost of $1,000, and the building of two miles of road, at a cost of $21,000, to the site of the proposed mills of the Great Lakes Pulp and Paper Co.

Raymond, Alta.—Control and operation of municipal waterworks and lighting systems may be taken over by the Ellison Milling Co.

Scotch Cove, N.S.—Contract let to A. W. Girroir and W F. MacKinnon, of Antigonish, N.S., for extension to breakwater.

Toronto, Ont.—York county council is considering following improvements to Industrial Home: Water supply system, at cost of $9,000; heating system, $7,000; rewiring, $2,500, and standpipe for fire protection purposes, $6,000.

Toronto, Ont.—Board of Control divided contract for 6,000 feet of fire hose as follows: 2,000 feet each to the Gutta Percha and Rubber, Ltd., and Dunlop Tire and Rubber Goods Co. and 1,000 feet each to the Goodyear Tire and Rubber Co. of Canada, Ltd., and the Canadian Consolidated Rubber Co.

Vancouver, B.C.—Plans for harbor work here are now being prepared by the Dominion government, and as soon as they are ready, tenders will be called for. Minister of Marine and Fisheries, Hon. C. C. Ballantyne, Ottawa.

Victoria, B.C.—Provincial government will at once call for tenders on the big Sumas dyking project. Approximate cost, $1,500,000. Minister of Agriculture, Hon. Mr. Barrow.

Winnipeg, Man.—A triangle, comprising 800,000 acres of land lying between the Saskatchewan River, the Carrot River and the Sepanok Channel, which, for an expenditure of about $1,500,000, could be reclaimed, will be brought to the attention of the Minister of the Interior.

Steam Turbine Driven Turbo-Blower Set

With Condensing Plant. For quick delivery from stock at very favorable price.

FURTHER PARTICULARS FROM

ESCHER, WYSS & CO.

112 Coristine Bldg., Montreal 368

Tenders Called For

EXTENSION OF TIME

CITY OF NORTH BATTLEFORD, SASK.

TENDERS FOR POWER PLANT EQUIPMENT

Sealed tenders, addressed to the undersigned, and marked, "Tender for Power Plant Equipment," will be received up to 5 p.m. on Saturday, December 6th, 1919, for two 250-h.p. Water Tube Steam Boilers, one Sheet Metal Stack, 50" x 60', and a quantity of Metal Smoke Flue.

Plans, specifications and all further information may be obtained on application to M. D. Cadwell, Superintendent of Utilities, City Hall, North Battleford, Sask.

ROBERT FARQUHARSON, City Clerk.
The City Hall, North Battleford, Sask.,
November 18th, 1919. 383

Time for acceptance of above tenders has been extended to 5 p.m., Saturday, December 20th, 1919.

Condensed Advs.

Advertisements under this heading at following rates per insertion, with fifty cents per insertion as minimum rate in any case; "Positions Wanted," one cent per word; all other condensed advertisements, three cents per word. Payable in advance; 50 per cent. extra if charged.

DRAFTSMAN WANTED.—Good general draftsman used to designing and drafting. State experience and salary expected. William Hamilton Company, Limited, Peterborough, Ont. 379

WANTED.—New or second-hand, one-boom concrete mixer, Austin cube or Koehring preferred. State size, location and length of time in use. Box 35, *The Canadian Engineer*, Toronto.

HELP WANTED.—Resident Engineer on Waterworks construction required at once. State experience. Returned man preferred. Should be college graduate. Box 37, *Canadian Engineer*, Toronto.

FOR SALE.—Twenty-one bound volumes of the Engineering Magazine, 1893 to 1905; twelve bound volumes of Engineering, of London, Eng., 1898 to 1903; three bound volumes of Engineering News, volumes 47, 48 and 52. Will sell separately or en bloc. Write, making offer to Box 31, *Canadian Engineer*, Toronto.

MANUFACTURER in Eastern Townships, having good facilities and considerable experience in the production of a wide variety of machinery lines, desires to undertake the manufacture (for the Canadian or export trade) of American or English machinery. Full particulars gladly upon request. Box 396, *Canadian Engineer*, Toronto.

FOR SALE.—1,100 h.p. Laval Steam Turbine and Generator; Worthington Centrifugal Pumps, Capacity 1,500 g.p.m.; Sturtevant Exhausters and Heating Coils; Cypress Tanks and Vats, all sizes; 100,000-Gallon Cypress Tank on 70-ft. Steel Tower; Steel Tanks, 20 ft. diam., 20 ft. height; Valves, Hydrants, Indicator Posts, etc. Write for full information and list of material to St. John Dry Dock and Shipbuilding Co., Drummondville, Que. 384

A Weekly Paper for Civil Engineers and Contractors

Present Status of the Sewage Disposal Problem

Efforts to Recover Valuable Nitrogenous Contents of Sewage Made Difficult by Colloidal Nature of Activated Sludge--Cities May Have to Dissolve and Oxidize as Much of Organic Material as Possible, Turning out Smaller Quantity of Stable Residue and Making No Attempt at Conservation

By Dr. GEORGE G. NASMITH
Director of Laboratories, Department of Public Health, Toronto

WHEN an interested person with the solution of some sewage disposal problem in mind begins to make a survey of the existing installations, he is soon struck with the fact that there appears to be no perfect sewage disposal plant in existence. Some will show one good feature, some another, but after a thorough investigation the investigator will be convinced that the most notable feature about the majority of sewage disposal plants is the apparent failure to achieve the object aimed at, or some marked nuisance in connection with the operation of the plants.

It seems to me that it has been the lack of appreciation by engineers of the principles involved in sewage disposal that has chiefly been responsible for the large number of offensive sewage disposal plants in this and other countries.

One factor frequently responsible for the improper operating of sewage disposal plants has been the failure of engineers to take into consideration the large amount of silt and detritus brought down in sewage, and to provide detritus chambers of sufficient capacity. As a result silt passes over into the sedimentation tanks proper and settles out in the form of compact deposits which prevent proper sludging of the tanks. The consequence is that decomposition of the sludge sets in, large quantities of offensive gases are given off, both in the tanks and during the sludging process, and a nuisance is created.

In other cases incomplete sewage disposal systems have been installed. These frequently consist of a system of screens, grit chambers and sedimentation tanks, the effluent being allowed to flow into the nearest stream or lake. If this effluent flows into a body of water too small to handle it, all the oxygen is absorbed from the water, the organic matter in the effluent settles out, anærobic action takes place, and again a nuisance is created, to say nothing of the possible danger from contaminated water supplies.

Sludge Treatment a Nuisance

Or again, when sludge is to be treated, a nuisance is almost certain to result, because sewage sludge cannot be rapidly dewatered or dug into ground and can only be kept from undergoing offensive bacterial putrefaction with the greatest difficulty.

In many cases where nuisances have arisen, the fault has not been that of the engineer, who originally designed the plant with a full knowledge of the subject of sewage disposal held at the time of its construction. Sometimes well-designed plants have been allowed to become public nuisances through mismanagement. In other cases the growth of the municipality has resulted in the plant being overloaded, with no attempt to remedy the trouble by properly extending the system.

All of these conditions have come within the experience of anyone who has studied the problem of sewage disposal at all extensively. In England, the writer has seen numerous small installations consisting of sedimentation tanks and bacteria beds which appear to be carried on with a comparatively negligible amount of nuisance. It is only a question of degree, however. If these small installations were increased to ten or twenty times their capacity, the negligible nuisance would become marked.

At Salford I saw the original activated sludge plant operating without the slightest odor upon a most objectionable-looking sewage containing large quantities of dye products and explosive manufacturing wastes. At Devizes I examined a very excellent installation of sedimentation tanks and trickling filters. This system was considered to be one of the very finest examples of its kind in England; there was little odor and the whole process was carried on in the open air.

Operation Is Important Factor

Whether there is a nuisance or not at any disposal works depends on the operation of the plant as well as on the installation, and as plenty of labor can usually be obtained in England, the plants there are, as a rule, well looked after.

In America it has been possible for engineers to install many sewage disposal plants that looked well on paper, because the local authorities did not know enough about the problem to tell whether the plans were suitable or not, and there was no central authority, or referee, with sufficient minute knowledge of the subject to whom the plans of the proposed installation could be submitted. This central, independent expert authority, or referee, has been established in Ontario and other provinces in the person of the sanitary engineer of the Provincial Board of Health, instead of the Board itself, as was the case in Ontario at one time.

The disposal of sewage in its various stages is absolutely dependent upon bacterial action. Bacteria are the agents which are employed to carry on the series of destructive processes which finally convert the organic matter present in sewage into inert inorganic salts and a humus-like residue which can no longer undergo active putrefaction. Two classes of bacteria may be employed, according to the result wished for: Anærobic and ærobic.

The anærobic type are hydrolytic organisms, and as a rule split up complicated organic materials into simpler organic materials, frequently with the production of hydrogen sulphide and other offensive gases.

Aerobic bacteria, on the other hand, tend to directly oxidize or burn up organic compounds, or their split products, into inoffensive, inorganic stable compounds, such as carbon dioxide, nitrates, sulphates and other salts. The final result of anærobic and ærobic action combined, which is presumably the general rule, is a stable organic residue called "humus."

Because of the nuisance which results from the ordinary anærobic or hydrolytic fermentation of sewage, the tendency has been to discard this process and employ ærobic methods wherever it is possible to do so. It is a simple matter to obtain a clear, non-putrescible effluent by passing the sedimented sewage over trickling filters, or by means of the activated sludge process, without any nuisance arising. The inoffensive treatment of sludge, whether from plain sedimentation tanks or from activated sludge process, has until recently proved very difficult, because sludge is putrescible and the only method yet known of digesting it to a non-putrescible residue is by the anærobic process.

What Treatment Must Involve

The treatment of sewage by modern methods must involve:—

1. The thorough screening of coarse material from the sewage.

2. The complete separation of grit and other readily sedimented inorganic matter in suitable grit chambers before the sewage passes over into the sedimentation tanks proper.

3. The complete separation of all organic material capable of being sedimented in special tanks.

4. The treatment of the effluent from the sedimentation tank on bacteria beds to form a clear, non-putrescible effluent.

5. The treatment of the sludge without nuisance to yield a non-putrescible, easily handled residue.

Of these phases, the third and fourth may be combined, as they are in the activated sludge process, while the treatment of the sewage by efficient screening and grit chambers is absolutely essential as a preliminary to any disposal system.

The object of the chemical engineer, or sanitarian, is to convert all the contained organic matter in sewage into inorganic matter, or something which is no longer putrescible. To be ideal, there should be no nuisance connected with any part of the process, from beginning to end—an ideal which only now we are beginning to believe possible of accomplishment.

The activated sludge process would have brought us pretty close to the ideal solution were it not for the fact that activated sludge is colloidal in character, will not readily separate from its water content, and is putrescible. But because of this drawback the most difficult task remains unsolved, and we must seek elsewhere for the solution of the sludge problem. According to our experience in Toronto, continuous aeration of activated sludge for two weeks will not produce a stable residue; it still has to undergo anærobic action before it can become a stable, inoffensive material.

Public Resents Stream Pollution

With the increase in knowledge on the part of the general public on questions of public health, there is a growing objection to the pollution of water-courses by sewage, not only because of the possible danger of typhoid fever and other intestinal diseases, but also from the aesthetic standpoint.

Of course, there are occasions, during periods of heavy rainfall and storms, when the sewage of any municipality, unless it has a special system of sanitary sewers, will have to be by-passed into the nearest stream or lake. This occasional pollution is not what people object to, but rather to the principle which approves of the deliberate fouling of our water supplies and their subsequent purification.

The dwellers on streams below towns are more and more resenting the conversion of those formerly limpid streams into foul and turbid water-courses because some tanner, manufacturer or town upstream throws waste products into them. And, because of this growing hostility to the interference of what are felt to be the reasonable riparian rights of property owners by the deliberate pollution of streams by irresponsible parties, it is becoming less easy for manufacturers and towns to solve their disposal problems by the simple process of carrying a pipe line to the nearest watercourse and letting their wastes empty into it.

The ideal method of sewage disposal, sought for so long and so patiently by sanitarians, is actually now appearing in sight. Gradually we have learned the basic principles involved in the disposal of sewage, and, because these are purely biological in character and could not be learned through laboratory experiments, but only from deductions based upon experiments on a very large practical scale, it has taken a long time to establish them.

What would constitute an ideal method of sewage disposal? To the writer it would mean the carrying on of the whole process without any nuisance whatever, at the minimum cost and with the production of a non-pathogenic and non-putrescible effluent which could be turned with safety into the nearest water-course. The entire process, moreover, should, if possible, be carried out in tanks of simple and economical design that would not involve an elaborate pumping plant or the construction of bacteria beds.

Leaving the small septic tank out of the question, every system of sewage disposal of any scale involves the separation of suspended material from the sewage, and treatment of the effluent and sludge independently.

Effluent Stable, Sludge Putrescible

It has hitherto proved impossible to digest sewage in tanks in such a way as to yield both a stable effluent and a non-putrescible sludge. The closest we have come to this is in the activated sludge process, where a clear, stable effluent is produced, as well as a partially stabilized sludge. If the activated sludge produced was a perfectly stable material which could be readily dewatered, we would have an ideal method, but the sludge from an activated tank is still colloidal and clings to its contained water with the greatest obstinacy; consequently, it cannot be readily dried out on any kind of filter beds, though apparently about 40% of its contained water may be readily removed by centrifugal action.

The prevailing methods of sewage disposal in America include the activated sludge system, plain sedimentation tanks alone or in combination with trickling filters, the double-tank system of Travis or Imhof, and sludge digestion tanks. The ordinary large septic or hydrolytic tank has to a large extent been superseded on account of the nuisance with which its operation is attended, and the various types of contact beds, which were common in England, but are now out of date, never gained a foothold here.

The small septic tank for household use is a very valuable method, because it is automatic, liquefies solids, and, since the whole process is carried on underground, is inoffensive. The liquefied effluent from the small underground septic tank flushes periodically into a system of underground tiles placed not far below the surface of the ground; from this tile system it soaks into the soil, and any organic matter present is destroyed by bacterial action, while any gases are absorbed by the soil.

An advance on the large septic tank was the double-chambered tank of Travis and Imhof. These types permit the sludge which settles out from the upper tank to fall through into the lower tank, where it undergoes digestion independent of the tank above it. Sometimes this kind of digestion is satisfactory and does not create bad odors; at other times the digesting sludge in the lower tank boils up into the second tank and is very offensive. Consequently, many of these double-chambered tanks have been abandoned. One very valuable fact was established by the process, namely, that it is possible under certain conditions to digest sludge anærobically without offense.

Sludge Valuable as Fertilizer

The activated sludge process, which is excellent in that it is carried out in tanks, removes all colloidal matter in suspension and turns out an excellent, clean and non-putrescible effluent, is also essentially a biological process. It depends, however, on an ærobic flora, quite different in character from that which operates in the anærobic systems mentioned above. The process produces a sludge which quickly separates from the sewage, leaving a clear and almost colorless supernatant water. Sludge presses or centrifugal action

will reduce the water content of activated sludge to about 60%.

It is interesting to note that in the further drying of activated sludge by artificial means, objectionable gases are given off which, unless carefully looked after, may create a local nuisance.

The fertilizer value of activated sludge is high, as both Bartow and Hatfield* and G. P. McKay and the writer† have pointed out. Mr. McKay and the writer have shown in actual outdoor plot experiments, subsequently confirmed by greenhouse plot experiments, that activated sludge, compared with barnyard manure, will produce yields of vegetables of extraordinary size. Results showed increases in the outdoor crop yield amounting from 100% in the case of lettuce to 290% in tomatoes, and even 550% in the case of Weatherfield onions. The results under glass, which have not yet been published, are equally remarkable.

Combination May Solve Problem

Owing to the difficulty and cost of dewatering, the trouble involved in the drying process, and certain other objections, the activated sludge method is not the last word on sewage disposal. It looks as though the solution of the sludge problem will depend upon a combination of the activated sludge process with sludge digestion or plain sedimentation tanks followed by trickling filters and sludge digestion. The latter will be controlled under definite conditions which are now fairly well established, and will be operated as a distinctly biological problem.

The practice to be followed will of necessity in small installations be more or less empirical, since expert assistants will not be available. This defect, of course, might be overcome by having the smaller sewage disposal plants placed under the indirect supervision of some qualified expert, who could keep them under proper working conditions and advise as to changes in methods of operation, additions to or modifications of the plant, from time to time as needed.

The principles underlying the activated sludge process and the trickling filter may seem to be quite different. As a matter of fact, they are identical. In the trickling filter some medium, whether it be stone or brush as in the Leaside plant, is employed, over which the sewage slowly trickles. The stone or wood after a time becomes covered with a slimy material which has the property of absorbing solids, colloidal material and other inorganic compounds from the thin sewage films flowing over it, and of converting this absorbed matter, through biological oxidation processes, into inert, non-putrescible, inorganic matter.

In the activated sludge process this same kind of slimy material which forms on the surface of a trickling filter is gradually produced by bubbling air through sewage held in tanks. When fresh sewage is agitated for some hours with this activated sludge by streams of fine air bubbles, the organic matter in the sewage is attracted to the activated sludge just as it was attracted to the slimy film on the stone or wood trickling filter, and is so altered that only inorganic, non-putrescible materials pass over in the clarified effluent.

Different Methods, Same Principle

In the one case the sewage circulates through the air over an activated biological medium; in the second case the activated biological medium is circulated through the sewage in association with large quantities of air bubbles. The combination of ærobic bacterial agent and air is identical in both methods. That this biological agent is identical in both cases was proved by the writer, who started a small activated sludge tank with ripened sludge collected from a lath trickling filter. The nitrification and clarification, which usually takes several weeks to develop, began at once, proving that the biological medium was one and the same, and that the processes were identical.

In the opinion of the writer, the complete solution of the sewage disposal problem will come about finally through a combination of the activated sludge process, or trickling filters, with sludge digestion. It may be that the activated sludge process will be the preliminary installation, followed by digestion tanks; or it may be that actual sewage digestion will be the first installation.

Brush Affords Greater Capacity

In one of the common types of sewage disposal plants, sedimentation tanks remove the larger part of the suspended organic matter, and the effluent is treated on trickling filters or oxidizing beds. These may be of stone, clinkers, brush or other material, and the general rate of treatment has been from two or two-and-a-half million gallons of sewage per acre per day on the older form, to seven million gallons per acre per day on the newer brush filter.

Where plenty of fall is available, trickling filters, particularly in small installations, will frequently be considered preferable to the activated sludge method. At the Leaside, or North Toronto, sewage disposal plant, one of the trickling filter beds, composed of stone, was at my suggestion replaced some six years ago with bundles of brush tightly packed together. Operating side by side for six years, the other old stone filters have treated from two to two-and-a-half million gallons of sewage per acre per day, while the brush filter has averaged six-and-a-half million gallons per acre per day.

The brush filter was simply the logical conclusion of experiments carefully conducted by us at our experimental plant to determine the greatest amount of filter medium which, allowing free access of air, could be packed in six feet of filter bed. This method, which was patented at the time, is free to those who wish to use it, and, since it is cheap and will reduce the amount of filter area required to one-third, there should be many places where its use should prove desirable.

It may be stated here that the brush to date shows absolutely no signs of decay, and is as sound as it was six years ago when placed in situ. With this method, of course, the sludge problem has still to be dealt with.

Can Digest Sludge Inoffensively

Though it has not been possible to digest sewage anærobically and obtain a non-putrescible residue without offense, it has proved possible to digest sludge without creating a nuisance. Watson, of Birmingham, has shown* that sewage sludge can be thoroughly digested on a huge scale without causing a nuisance. At Birmingham the fresh sludge from ordinary sedimentation tanks is drawn off and pumped into digestion tanks, receiving before it enters these tanks one-fourth its volume of old, thoroughly ripened sludge. This seeds it with the proper bacterial flora, and, provided the temperature is right, digestion will progress to a conclusion without the production of foul odors. At the end of four months the sludge is thoroughly digested, is no longer putrescible, is reduced in quantity and is readily drained on ordinary drying beds.

The action which occurs in the Birmingham sludge tanks is apparently the same as that which occurs in a properly operated Imhof tank. Dr. Carl Imhof, while on a visit to Toronto in 1913, told us that it was quite feasible to digest sewage sludge without offense. He advocated the mixing of one part of Emscher (Imhof) sludge with one part of fresh sludge, and stated that a ripened sludge would be produced in one week. One part of this could then be mixed with an equal volume of fresh sludge, and so on, ad infinitum. The Emscher sludge itself takes from nine to twelve months to prepare.

Those attempting to solve the sludge problem have in mind two definite objectives. In the first case, an attempt is being made to save the tremendous waste of valuable nitrogenous matter present in sewage, and retain it in the

*See Journal of Industrial and Engineering Chemistry, Vol. 8, No. 1, January, 1916.

†See article, "Fertilizer Value of Activated Sludge," by G. G. Nasmith and G. P. McKay, in *The Canadian Engineer*, May 2nd, 1918, page 377.

*See "The Utilization of Sewage Sludge," by John D. Watson, in *The Canadian Engineer*, October 30th, 1919, page 420.

form of fertilizer. The success of the activated sludge process would seem largely to depend upon the fact that a revenue is expected from the dried activated sludge. From the standpoint of conservation alone, particularly if a satisfactory and economical process is found for dewatering the sludge, there is everything to be said for the process, and, particularly in cities which do not possess tanneries, there are no objections to the use of this material as fertilizer. On the other hand, it is doubtful whether the activated process will be popular with small municipalities because of the expert care necessary in operating the plant. In the second case the tendency is to first dissolve and then thoroughly oxidize as much of the organic material in the sewage as possible, and turn out the smallest possible quantity of a stable residue.

In the latter case no attempt would be made to obtain any income, and the process would be worked out along lines of operation that would be, so far as possible, automatic.

Like many others, we were in favor of the conservation idea, and the saving of as much as possible of the nitrogen and other fertilizer ingredients in sewage by the activated sludge process, until our work and that done elsewhere convinced us of the as yet unsolved difficulty of rapidly and economically drying the sludge.

Even if the material could be produced economically and without nuisance, it is realized that the sale of same and consequently the economical operation of the plant would be a purely business proposition, in competition with established industries, and, in case of success, with other municipalities.

For these reasons the writer has come to the conclusion that the second process will be the one generally adopted. It appears as though the final solution of the sewage disposal problem will come about eventually through a combination of the activated sludge process or trickling filters in combination with sludge digestion tanks. It may be that the activated sludge process will be the preliminary installation, followed by digestion tanks. It may be that actual sewage digestion tanks will be the first installation, followed by the activated sludge process. Certain preliminary work, which has been carried on by us for a year, shows very promising results, and it is hoped that in the near future we will have information and data for publication as to the results obtained.

Letter to the Editor

COST-PLUS-FIXED-FEE CONTRACT

Sir,—In your issue of September 11th, the article by A. E. Wells, entitled "Cost-Plus-Fixed-Fee Contract," makes it quite clear that the method is very advantageous to the contractor who does the work.

Will you permit me to say a few words concerning what cost-plus-fixed-fee means to owners, and incidentally to touch upon the question of what it means to the small-fry contractors who are ambitious to expand?

This is what it means to the owners:—

First.—Placing themselves absolutely in the power of the contractor, who can make the work cost as much as he likes.

Second.—Placing themselves at the mercy of all the workmen on the job; for the latter cannot be induced to labor faithfully when they know that the "boss" will lose nothing by their idleness, no matter how honest may be the intentions of the contractor about keeping down the expense.

It is useless to deny the correctness of these two statements, for anyone with common sense must acknowledge it. While it is practicable to improve this method materially for the owner by substituting a sliding-scale fee for the fixed fee, even this will not protect him effectively, unless there be something in the nature of a penalty for the contractor, either to prevent him from neglecting to push the work or to make him pay for his negligence. A limit of total cost which can be increased or reduced properly, in order to provide for an increase or decrease in the estimated total quantities of materials, will prevent the owner from being excessively robbed, and still will give the contractor every opportunity to come out whole in the case of all but extraordinary hard-luck.

Such a method I expounded in a paper recently published by "Contracting," of Chicago.

[NOTE.—This article is reprinted for the reader's convenience, on page 527 of this issue of *The Canadian Engineer*. —EDITOR.]

It outlines an ideal, just, scientific and perfectly feasible method of contract-letting and profit-sharing,—one that is fair to both parties by making the owner and the contractor partners on the job, thus tending towards harmony and towards the utilization of every practicable method of legitimately keeping down the cost.

My scheme could be enlarged slightly in the interest of both the contractor and the owner by arranging in the specifications for a modification of the limiting cost by a ratio based upon the ratio of general average rise or fall of workmen's wages during the progress of the work. It would not be difficult to draft such a clause upon truly equitable lines.

Again, my method could be amended in the interests of labor by arranging that the contractor and the owner, immediately after the final settlement, shall each turn back a certain percentage of his declared profit (say, 20%) into a fund, which fund shall be divided among all the employees who have stayed on the work until its completion or until their services were no longer needed, the amount of each individual's share of the bonus being directly proportional to his total salary or wages in comparison with the sum of all salaries and wages. Such an arrangement would tend to make everyone on the job do his utmost to keep down the cost and to work faithfully and to the best of his ability.

And now a word as to how cost-plus-fixed-fee affects the small-fry contractors. Is it not evident that it will militate towards cutting them out of bidding? When an owner is willing to let any work on a cost-plus basis, he naturally wants to award it to a large contractor of means who has an established reputation for fairness and efficiency. That would practically mean letting all contract-work without competition,—and contractors as a body would object seriously to any such procedure. It is true that the owner might call for competitive bids by letting each bidder name a lump sum for his fixed fee, and awarding the contract to the competitor who names the lowest figure; but the adoption of such a method would often result in serious trouble, delay and expense.

It would be a great benefit if there were evolved and adopted, with the least possible delay, a method of contract-letting and profit-sharing that should always prove satisfactory to both parties to the agreement. By having it first discussed thoroughly in the papers, then seriously considered by a small committee representing the various organizations of engineers, architects, contractors and bankers, so as to determine tentatively some standard method for formal approval by each of the said organizations, the result desired could be attained. The benefits to be derived by the adoption of such a standard are far beyond the ability of anyone to predict.

J. A. L. WADDELL,
Consulting Engineer.

Kansas City, Mo., December 1st, 1919.

Applications are being invited by W. Foran, secretary Civil Service Commission of Canada, Ottawa, Ont., to fill the following vacancies: Instructor in mathematics, Royal Military College, Kingston, $1,800 per annum; engineering clerk, Topographical Surveys Branch, Department of Interior, $1,260 per annum; inspector of gas and electricity at St. John, N.B., $1,260 per annum. The last mentioned position is open only to residents of the province of New Brunswick.

SASKATCHEWAN'S PUBLIC FERRY SERVICE

By G. A. Palmer
Department of Highways, Regina, Sask.

THERE are 42 ferry crossings in Saskatchewan; all of these are important links in the main road system of that province. The ferries are operated by the Department of Highways and are free during daylight hours; they are accessible after dark, but a toll is then charged by the ferrymen.

In the pre-Rebellion days, a few scows were operated by the Indians and half-breeds at three or four of the main crossings, and under the government of the North-West Territories these crossings were brought under recognition and the ferrymen received licenses to operate at a fixed rate of tolls. When the provincial government assumed control in 1905, this system was superseded by establishing

Fig. 1—Standard Saskatchewan Ferry Scow

paid ferrymen at all new crossings, the old licenses being gradually eliminated, and in 1912 a system of free ferriage was established, the ferry service was unified and the scows and tackle of all crossings were brought to a government standard.

The growth of the ferry traffic from an occasional rancher's rig or pioneer's cart to the present-day heavily loaded grain tank, drawn by six horses or moved by motor power, and automobile traffic, reflects the short and rapid history of the development of the agricultural and cattle industry in Saskatchewan.

A comparison of the units of traffic carried by this ferry service for the last three years is interesting: —

Year 1916	.....	127,677
" 1917	.....	465,822 "
" 1918	.....	604,027 "

Fig. 2—South Saskatchewan River

Also the comparison between the decline of the wagon traffic and the increase of the automobile traffic:—

		Wagons.	Automobiles.
Year 1916	.....	122,677	25,738
" 1917	.....	107,270	60,386
" 1918	.....	111,770	103,928

There are required for Saskatchewan's ferry service 61 standard scows and 61 rowboats; 102,000 ft. of 1¼-in. steel

Fig. 3—Ice Makes Landing Difficult

cable for the main cables suspended from towers on the river banks, and upon which cable the scow travellers run; 48,000 ft. of ¾-in. steel cable for temporary crossings when the channel at the main cables becomes obstructed by moving sandbars; and 90,000 ft. of ⅜-in. steel cable. This small cable passes from the shore to the scow and is reeled on a winch to enable the ferryman to pass stretches of slack water in places where the current forms eddies which do not promote the progress of the scow.

The ferry season commences about the middle of April, and closes when the rivers are so choked with ice as to

Fig. 4—Straw Road Across Sandbar

render it dangerous to cross; this occurs any time from the end of October to the first of December.

The service last season cost the government $120,000, this sum covering the ferrymen's wages, new construction, renewals of scows and cables and tackle, and the maintenance of the approaches to the ferries. In connection with the latter item, approximately 6,000 lineal yards of road were built and maintained during low water, and for the consolidation of sandbars some 350 tons of straw and litter were hauled, with an average haul of three miles.

The present standard ferry scow (see Fig. 1) is 18 ft. in width and 52 ft. in length with two 12-ft. aprons extending beyond the ends of the scow. The carrying capacity of the new boats is figured to take care of four heavy tanks of wheat at one load.

The service is managed by a small office staff at Regina, one field inspector and usually two small construction and maintenance crews who are kept constantly in the field all the year, overhauling the boats in the winter and attending to repairs and approaches in the summer.

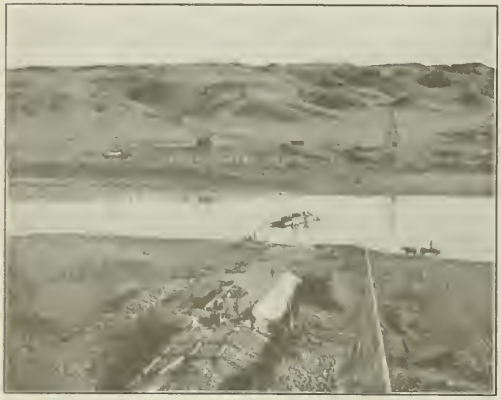

FIG. 5—CONSTRUCTING PERMANENT APPROACH TO FERRY

Fig. 2 indicates the characteristics of the South Saskatchewan river for 250 miles east of the western boundary of Saskatchewan. This view illustrates the sandbars which form at one level of the water, re-form, move and disappear at succeeding stages of the water. This natural feature of this section of the river makes the operation of ferries a difficult problem for the department to contend against. The road in the foreground is a typical road entry to an ascent from the river level to the plateau, which in some places is as high as 300 ft.

Fig. 1 is a fair-weather scene; Fig. 3 shows the difficulties of ferriage prior to the setting in of the severe

FIG. 6—PERMANENT APPROACH COMPLETED

weather. The river is full of "slush" ice, which forms on the ferry scow and obstructs the landings. The ferrymen are required to operate their boats under these conditions as long as possible consistent with safety. In Fig. 3 on the far side of the river can be seen one of the standard cable towers. At most crossings one of these towers is required at each side of the river. The cables (1¼-in. crucible cast steel cables with hemp centres) are suspended from the top of the towers and it is upon these cables that the pulleys of the travellers run. The travellers are connected with the ferry scows by ½-in. cables, which can be seen in Fig. 1.

Fig. 4 shows one method of making a solid road across the loose sand of the bars at points where the ferry scow cannot make a good natural landing. The dark material is successive layers of straw (preferably flax straw) which binds into the sand and makes a solid road for the heaviest kind of traffic.

A permanent ferry landing consists of a rampart of boulders with a concrete cover, the centre being laid with planks. Fig. 5 shows an approach road in the course of construction; also the South Saskatchewan river at its narrowest point, extreme low water. On the far bank the road can be seen entering the hills. The height of the tower on the far bank is 60 ft. The hills in the background are characteristic of the river benches in this vicinity. Fig. 6 is a "close-up" of the completed permanent approach.

TOWN PLANNING IN RELATION TO INDUSTRIAL DEVELOPMENT*

BY C. W. KIRKPATRICK
Industrial Commissioner, Hamilton, Ont.

YOU cannot get the most or the best out of a man unless he is happy and contented. High wages and short hours are not, in themselves, sufficient to make him either. He demands, and he is entitled to, the right to live, and unless you provide him with proper living conditions for himself and his family he will never prove 100% efficient.

I cannot claim originality for either the above paragraph or the thoughts it expresses. They are the words spoken to several others and myself by H. S. Firestone, head of the great Firestone Tire & Rubber Co., but they struck me with much force, and the more I have turned them over in my mind, the more have I become impressed with the idea that they have probably had much to do with Mr. Firestone's success. And they sum up briefly and concisely the few remarks that I intend to make. They may not appear to have any direct bearing on the subject, "Town Planning in Relation to Industrial Development," but when you analyse them I think you will agree with me that they tell pretty nearly the whole story.

In my comparatively brief experience as commissioner of industries for the city of Hamilton, I have found that the first concern of practically all large manufacturers is labor. The availability of a labor supply concerns him more than any one other thing, and the quality of that labor is to him of quite equal importance. In inquiring into the quality of the available labor supply, he invariably seeks a first-hand knowledge of housing conditions. If he finds that the workingmen of the city are properly housed, it does not take much more to satisfy him that the quality of the labor is good, but if on the contrary he finds that the particular class of labor in which he is interested is housed in shacks or tenements, or that the families of the workmen are surrounded by conditions that are not congenial or healthful, it takes more than the persuasive eloquence of an industrial commissioner to convince him that in that community he will find that which is most essential to the successful conduct of his business—efficient labor. In support of that statement (you will pardon me if I make another local reference), a few weeks ago H. W. Hoover, general manager of the Hoover Suction Sweeper Co., of Canton, Ohio, was asked—not by myself but by an indirect representative of the Department of Trade and Commerce—why he had selected Hamilton as the location for the company's Canadian plant, and this is what he wrote in reply:—

"First of all we were most favorably impressed with the seemingly ideal living conditions of the laboring people. The large percentage of these folks who owned their own

*Address at the Southwestern Ontario Town Planning Conference, Hamilton, Ont., November 27th and 28th, 1919.

homes impressed us with the fact that Hamilton must have an ideal labor market."

I trust that I have now successfully connected the expressed thoughts of Mr. Firestone with the subject of this paper, for it has been my aim to show that the city or town that does not give thought in the laying of its development plans to the proper housing of its working people, is badly handicapped in the race for industrial supremacy.

Living at Factory Door

It would be presumptuous on my part to suggest just what class of house is best suited to the requirements of the workingman or is most calculated to do its part toward bringing him and his family that measure of contentment necessary to his efficiency, but I have my own ideas regarding where that house, whatever the plan, should be located; or, rather, where it should not be located. Invariably when it is announced that a large new industry is about to locate in a certain district, there is a rush of builders into that district and the foundations of so-called workingmen's homes soon begin to make their appearance, usually before building operations are started on the factory itself. This, in my opinion, is a mistake. It has been my experience that the average workingman, while desirous of being fairly convenient to his place of employment, is still more desirous of being far enough away from it that it will not be staring him in the face every time he opens his front door, a constant reminder that his hours of rest and recreation are few and that the whistle will soon again be recalling him to toil.

It is quite true that houses built close to the sites of new industries invariably find ready sale or are easily rented, but that is usually because the prospective purchaser or tenant has no choice in the matter. Were they to be consulted, I believe that at least 75% of them would say that they would much prefer to be a few blocks distant but that circumstances forced them to take what they could get. In fact, provided with proper means of transportation, it is my opinion that a large majority of the workingmen would, for the sake of their families, if not for their own sakes, prefer to reside a mile or two from their places of employment, where their growing children would be far removed from the noise and grime of the workshop.

I was recently in a western city where some of the residents expressed great pride in a housing scheme that had been carried out for the benefit of the people employed in a certain factory district. "A model city," they called it. Being interested, I took time to pay the district a visit. What I found was a number of pretty houses, well paved streets and attractive boulevards, but surrounded on all sides by existing factories or factory lands. "If this is a model city, then give me the old-fashioned kind," was the thought that came to my mind, and when I afterwards had an opportunity to talk with the occupants of some of those homes, who, by the way, were not laboring men at all, I found that they were residing there because they could not find any other place to reside.

Industrial and Residential City

I have heard it said that an industrial city cannot hope to become a residential city in the sense that a residential city should be a thing of beauty. The claim that I am about to make would probably come with better grace from someone else, but I cannot refrain from saying that right here in Hamilton we have the answer to that statement, for here nature and man have combined in the building of a City Beautiful and an industrial centre. With but a few exceptions, Hamilton's larger industries are located in the northeast section of the city, on the harbor shore, where the prevailing winds blow the smoke, dust and objectionable odors out over the waters of Hamilton Harbor and Lake Ontario, where they can do no harm.

The residential sections, on the other hand, lie to the south, beneath the shelter of what we are pleased to call "Our Mountain," and where there is little, if any, possibility of their being marred by the industrial life of the

(Continued on page 531)

CORRUGATED PAPER USED TO SEPARATE WOOD BLOCK IN PAVING ST. THOMAS TRACK ALLOWANCE

By John Stanley Crandell
Consulting Engineer, General Tarvia Dept., the Barrett Co.

WOOD block pavement is being laid in the track allowance of the St. Thomas (Ont.) municipal railway by a new method. The old pavement was brick on a sand cushion. When it recently became necessary to replace the worn rails, it was decided to repave at the same time with wood block.

The concrete base which surrounds and covers the sleepers, was brought up so that when the wood blocks are

Spacer in Place Between Rows of Block—Roll of Spacer Material in Background

laid on it they are flush with the top of rail. Instead of laying the blocks on a sand cushion, the smooth concrete base is given a paint coat of paving pitch (145 degs. melting point, cube-in-water method) and the blocks are laid on this pitch paint coat as soon as it has hardened. Hardening takes only a few moments.

The rows of blocks are separated from each other by strips of corrugated paper $1\frac{1}{4}$ ins. wide by $\frac{3}{16}$ in. thick.

Squeegeeing Pitch into Joints

The joints are therefore about $\frac{3}{16}$ in. wide, or less if the blocks are lightly rammed. The joints so formed are then filled to about one-half their depth with coal tar pitch, and the remainder of the joint is swept full of clean sand.

The spacer of corrugated cardboard was used for the first time in June, 1919, in Bridgeport, Conn., in the track

allowance of the Connecticut Co. St. Thomas is the first Canadian city to use it. It permits the pitch filler to find its way to the bottom of every joint, thus insuring a waterproof pavement; it prevents the movement of the pitch after it settles in the joint, and therefore stops effectively any running of the pitch on hot days; and it provides a joint sufficiently wide to take care of any expansion that may take place in the blocks. As the blocks are laid in a pitch paint coat, and as the joints are waterproofed with pitch filler, five of the six faces of each block are protected with pitch.

By filling the joints only half full of pitch, much of the objectionable bleeding often associated with wood blocks is eliminated. The sand that fills the remainder of the joint eventually mixes with the pitch to form a pitch-sand mastic, and an ideal filler is the result.

Along the web of rail a strip of bituminized felt is laid. Paving pitch is poured around this so as to waterproof the pavement from rail to rail.

The work is being done under the direction of James A. Bell, consulting municipal engineer and acting city engineer, and under the immediate supervision of W. C. Miller, assistant engineer.

AMHERSTBURG FILTER PLANT

TO Charles W. Tarr, vice-president of Morris Knowles, Ltd., consulting engineers, Windsor, Ont., *The Canadian Engineer* is indebted for the two accompanying views of the recently completed water filtration plant at Amherstburg, Ont.

An article by Mr. Tarr, briefly describing this plant and relating the history of the Amherstburg waterworks,

BRUNNER-MOND CO.'S FILTRATION PLANT RECENTLY COMPLETED AT AMHERSTBURG, ONT.

appeared in *The Canadian Engineer* for June 5th, 1919. The plant was constructed by the Foundation Co., Ltd., of Montreal, for the Brunner-Mond Co., Ltd., of Amherstburg, who are largely interested in the welfare of that industrial community and decided to furnish it with pure water. The plant was designed by Morris Knowles, Ltd. The filter equipment

ANOTHER VIEW OF THE AMHERSTBURG WATER FILTRATION PLANT

was furnished by the Norwood Engineering Co., of Florence, Mass.

The Canadian channel of the Detroit river is the source of supply. The pumping plant is near the river bank. Power is supplied by the Brunner-Mond Co. and by the Hydro-Electric Power Commission to motor-driven centrifugal pumps. There are duplicate coagulating basins, each affording six hours' coagulation. A concrete tank of 35,000 gals. capacity provides wash water for the filter beds, which have a capacity of 1,500,000 gals. daily, with space for an additional unit when needed. The clear water reservoir has a capacity of 100,000 gals. There are three low-lift pumps and three high-lift pumps, each with capacity of 500 Imp. gals. per minute.

RECENT PUBLICATION

MANUFACTURE OF CHEMICALS BY ELECTROLYSIS.—By Arthur J. Hale; edited by Bertram Blount; published by Constable & Co., Ltd., London, Eng.; 80 pages and cloth cover; 5½ by 9½ ins.; price $1.50 net. The chapter headings are: Electrolytic Hydrogen and Oxygen, Ozone; Production of Per-Salts and Hydrogen Peroxide; Nitric Acid, Hydroxylamine, Hydrosulphites, Fluorine; Electrolytic Preparation of Pigments and Insoluble Substances; Electro-Osmotic and Electro-Colloidal Processes; Electrolytic Reduction of Organic Compounds; Oxidation and Substitution of Organic Compounds.

Correction.—The titles of the two illustrations on page 516 of last week's issue were accidentally transposed. The upper photograph shows the Regina warehouse of the Robert Simpson Co., Ltd., while the building shown in the lower photograph is the publishing plant of Rand, McNally & Co.

The secretary of the British Columbia Technical Association has forwarded to *The Canadian Engineer* the following report of the association's monthly meeting held November 17th, in the Board of Trade rooms, Vancouver: "Satisfactory reports were made on various phases of the association's activities and new plans for future action were outlined. The association has taken an active part in endeavoring to improve the status and salary grading of technical men in the Dominion Civil Service, and for several months past has been in constant correspondence with the authorities at Ottawa regarding the matter. Similar action has also been taken with regard to the regrading taking place under the provincial Civil Service Commission. The committee report at the meeting indicated that while the provincial association was given an opportunity of conferring through a committee with the regrading authorities, the committee chosen did not contain a representative of the technical men in the service. So while the Civil Service Association might perform valuable functions for the general clerical branches of the service, it appeared that in this instance the interests of the technical men were not being adequately presented. A delegation was appointed which left for Victoria the following day to interview the Civil Service Commissioner on the matter. A discussion took place on the hitherto inadequate part which engineers and other technical men have taken in public matters, resulting in it being left to non-technical men to occupy public positions which vested them with control over expenditure of money on engineering and other technical work. A public service committee was formed, with instructions to work to promote and encourage increased interest among technical men in municipal, provincial and national government affairs."

IDEAL CONTRACT-LETTING MADE PRACTICABLE

By Dr. J. A. L. Waddell
Consulting Engineer, Kansas City, Mo.

IS it not obvious that anyone who lets a contract on the "cost-plus" basis places himself absolutely at the mercy of the contractor and the contractor's employees? It is true that the specifications often contain restrictions which tend to lessen the contractor's power to take advantage of the client; but their enforcement would be very troublesome, and would generally involve litigation with its attendant delay and expense.

Even if the contractor has every possible desire to expedite the work in the interest of the client, he cannot prevent his men from taking life easily and "soldiering" on the job. When they feel that their indolence or negligence will cost "the boss" nothing, but, on the contrary, will probably add to his profits, they cannot be induced to labor with the same amount of energy which they would employ if they knew that upon their efforts depends his success or failure.

Most people will acknowledge that the percentage of truly conscientious contractors is not as large as one hundred, . . . but how much smaller is that of truly conscientious workmen! I do not deny that there are workmen who always give a *quid pro quo* and who are upright and honorable in all their dealings; but alas! they are sadly in the minority. Their number is so small that they are unable to induce their co-laborers to exert themselves any more than they are compelled to, unless, perchance, they are paid by the job instead of by the day or hour.

By the way, when it is practicable, such a scheme of paying the workmen is an improvement on that of time-compensation, because it provides a great incentive to effort; but, at the same time, it also serves as a strong temptation to scamp the work. With close supervision, however, and a strict enforcement of the clause in the specifications relating to the taking out and replacing of defectively built work, the employees soon learn, through the fines and penalties enforced by the contractor, that scamping does not pay, and that the old adage of honesty being the best policy is just as applicable now as it was when first enunciated.

Unsatisfactory Contract Forms

So much from the client's point of view, and now let us discuss the question from that of the contractor. In the days of hard times when contractors are willing to take work at low figures, and even below cost, in order to keep their force together, the public in general, especially as represented by companies and municipalities, is prone to take advantage of them by insisting that work be let by the lump sum, and by throwing upon the unfortunate "successful bidder" not only the risk of loss from rising prices of materials and labor and from unforeseen contingencies, but also, in many cases, from excess of quantities above those given in the specifications. This is accomplished by inserting in the latter a most unjust clause compelling each bidder to verify for himself both the quantities stated and the character of the conditions described. The bidders, hungry for work, accept this clause without comment, but with the mental reservation that, in case of hard luck, they will, by some means or other obtain extra compensation, even if they have to carry the controversy into the courts.

In nineteen cases out of twenty it is unjust to bidders to ask them to name a lump-sum compensation for doing work, unless provision be made for a variation in the quantities of materials upon which they tender. If provision be arranged for such variation, the method of letting is no longer that of the "lump sum," but reduces to a modification of that of "unit prices."

The latter method is certainly the more logical, and yet it is far from being entirely fair to the contractor; because, while it provides against loss through excess in quantities of materials, it leaves him open to the possibility of still greater loss through changing prices, onerous unanticipated conditions, and disastrous happenings beyond his control.

The client is the proper party to assume the principal risks inherent to the work, provided that the adverse happenings be really unavoidable by the contractor, and that the latter take every reasonable precaution against disaster or loss.

Principles of Satisfactory Forms

From the preceding it is evident that the "cost-plus," the "lump-sum," and the "unit-price" methods of letting contracts are not only faulty but also unjust to one or other of the two parties to the agreement; consequently, the question arises—"Is there not some method which will be just and fair to both?" That question, I claim, can truly be answered in the affirmative; and I shall now proceed to explain such a method in complete detail.

Let the specifications, which should invariably be drafted by an engineer who is acknowledged to be an expert in the class of work covered in the proposed contract, be complete and thorough in every detail, recording all that is known concerning the governing conditions; pointing out all features concerning which there is any uncertainty; tabulating

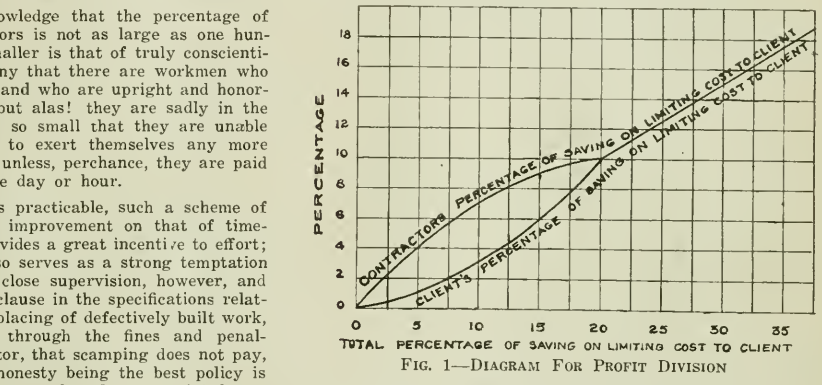

Fig. 1—Diagram For Profit Division

as accurately as possible the estimated quantities of all the materials that will probably enter the construction; providing a justly-drawn clause for unclassified work and the payment therefor; calling for each bidder to name a lump sum so much above his estimate of total cost that there is practically no danger of the actual cost exceeding it, which sum (after modification as hereinafter indicated) shall be the greatest that the client can be called upon to pay for the completed work; naming such properly balanced unit prices for all the materials that, when they are applied to the quantities thereof given in the specifications, the sum of the several ensuing estimates of cost shall exactly equal the limit of cost set in the contract, which unit prices are to be adopted when computing the final payment for the entire work; providing a surety-company bond for the faithful performance of the work and guaranteeing the client against having to pay more than the limiting sum agreed upon (as finally modified); and adopting the following method of profit-sharing between the contractor and the client.

Method of Profit-Sharing

An accurate estimate of cost of every detail of the work from start to finish is to be kept by the contractor and verified by an accountant in the employ of the client, so that the total profit on the job may be ascertained by deducting this total cost from the maximum figure named in the contractor's tender and afterwards embodied in the contract (modified, however, as hereinafter described). This profit is to be shared between the contractor and the client as indicated in the profit diagram. It should be clearly understood that every direct and indirect expense to which the contractor is put in doing the work, after the contract is signed, is to be included in the cost—all overhead expenses of every kind, plant deterioration, traveling expenses, supervision, and salaries, excepting only that the contractor

himself is not entitled to any salary. In the case of a firm being the contractor, the head of that firm should receive no salary; but if any of the juniors devote their time exclusively to the job, it would be legitimate to allow them reasonable salaries, equivalent to what would have to be paid to regular assistants. All such matters, however, should be stipulated in the contract.

In order to determine, after the entire job is finished, the amount due the contractor, the actual quantities of materials recorded are to be multiplied by the unit prices named in the contract, and to the sum of these is to be added the value of all unclassified work (usually denominated "extras"); then from the sum is to be subtracted the lump sum named by the bidder and incorporated in the contract. The ratio which this difference (either a positive or a negative quantity) bears to the said lump sum named by the contractor in bidding is to be figured and adopted in the employment of the diagram of "corrective ratios" for the said difference.

Application of Corrective Ratio

There are two reasons for applying this corrective ratio: First: in the case where the actual quantities of materials exceed the estimated ones of the specifications, it would be

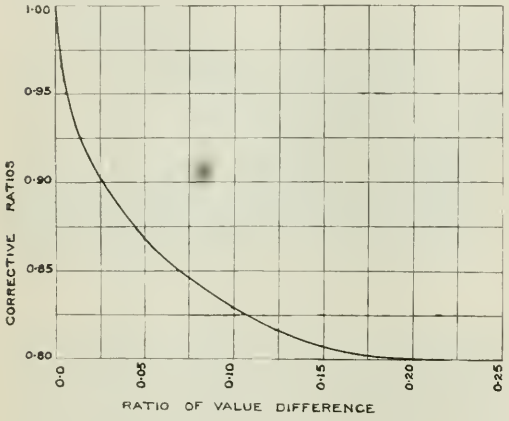

FIG. 2—DIAGRAM OF CORRECTIVE RATIOS

hardly fair to the client to apply to the excess those unit prices which produce his tentative limiting expenditure. Second: in the case where the actual quantities of materials are less than the estimated ones, it would be unjust to the contractor to use the high unit prices on the diminution quantities, not only because of the great difference between these and the unit actual-costs, but also for the reason that the total overhead charges would be about the same for the estimated total quantities as for the diminished amounts.

In the corrective-ratio diagram it will be noticed, that, after the ratio of value difference (due to increase or diminution of quantities of materials) reaches 0.2, the "corrective ratio" remains constant at 0.8, which corresponds approximately to actual cost conditions. The object of this is to provide that the contractor shall not be too much benefited by an abnormal increase in quantities, nor, on the other hand, shall he obtain too much advantage because of an abnormal diminution thereof.

To utilize the corrective-ratio diagram, look on the line of abscissae for the ratio of cost difference, pass vertically upward to the curve (or right line, as the case may be), then horizontally to the extreme left vertical, which will indicate the corrective ratio required. Next multiply the previously computed difference by this corrective ratio and add the result to or subtract it from the limit stipulated in the contract. The result will be the corrected limit, from which must be subtracted the total cost so as to determine the amount of profit to be divided between the contractor and the client, as per the profit diagram.

In order to show the *modus operandi* of this method of profit-sharing, let us assume the following case, in which the estimated quantities are exceeded.

Lump-sum limit tendered $1,700,000
Value of total work done per unit-price list and clause re unclassified work 1,855,000
Total cost of work 1,575,500
Difference = $1,855,000—$1,700,000 = $155,000.
Ratio of difference = $155,000÷$1,700,000 = 0.091.
From Fig. 2 we find the "corrective ratio" to be 0.833; then the corrected difference = $155,000×0.833 = $129,115.
Corrected limit = $1,700,000+$129,115 = $1,829,115.
Profit = $1,829,115—$1,575,500 = $253,615.
Percentage of total profit = $25,361,500÷$1,575,500 = 16.1
From Fig 1, we find the division of this profit to be as follows:—
Contractor 9.4%
Client 6.7%
Total payment to contractor
= 109.4×$1,575,500 = $1,723,597.

Now let us investigate a case in which there is a diminution in the estimated quantities of materials.

Lump-sum limit tendered $1,700,000
Value of total work done per unit-price list and clause re unclassified work 1,615,000
Total cost of work 1,310,000
Difference = $1,700,000—$1,615,000 = $85,000.
Ratio of difference = $85,000÷$1,700,000 = 0.05.
From Fig. 2 we find the "corrective ratio" to be 0.87, then the corrected difference = $85,000×0.87 = $73,950.
Corrected limit = $1,700,000—$73,950 = $1,626,050.
Profit = $1,626,050—$1,310,000 = $316,050.
Percentage of total profit = $31,605,000÷$1,310,000 = 24.1.
From Fig. 1, we find the division of profit to be as follows:—
Contractor 12.05%
Client 12.05%
Total payment to contractor
= 1.1205×$1,310,000 = $1,467,855.

Advantages

The advantages of this method of contract-letting are as follows:—

First.—While it is true that the client at the outset does not know exactly what the work is going to cost him, he is positive that it will *not* cost him more than a certain amount, provided that his engineer's estimate of quantities of materials is about right, as, generally speaking, it certainly ought to be.

Second.—The client has the satisfaction of feeling that, even if, in his opinion, the limit bid by the contractor is excessive, and that the profit on the job in consequence, will be too large, the said profit will be shared between them on a fifty-fifty basis.

Third.—All the advantages of competitive bidding are retained by this method of tendering, because all that a bidder has to do is to name a limiting lump sum with certain unit prices, and to make sure that the latter, when properly applied to the quantities of materials given in the specifications, will produce a total value equal to the said limiting lump sum. All bids will be upon exactly the same basis, no modification of the stipulated method of tendering being permitted, hence the selection of the bidder will be governed solely by the lowest lump sum named, provided, of course, that the one tendering it possesses the necessary experience, capital, plant, and general reputation for doing good and satisfactory work.

Fourth.—The contractor, if he was not too keen in bidding, knows that there is almost no chance whatsoever of his losing money on the job, and that the harder and the more intelligently he works the greater will be his profit.

Fifth.—The division of total profit given in the profit diagram is eminently equitable, in that, when the amount is small, nearly all of it goes to the contractor, and, as it augments, a continually increasing proportion of it goes to

the client, up to the point where the total profit amounts to 20%, after which the partition is on a fifty-fifty basis. This point was selected as being the one above which a contract is generally deemed by contractors to be good, slightly below which it is only fair, and much below which it is bad; for it corresponds to a net profit of 10%. That is as small a margin as is generally deemed safe for any bidder to tender upon, and yet it constitutes a satisfactory profit on a finished job. As for limiting the client's share of the profit to one-half—that is reasonable and just, because he would have no moral right to receive more than his partner, the contractor. If the client's share were allowed to increase beyond the point of equal division, it is conceivable that, with a very large prospective total profit, the contractor could save money for himself by making the work more expensive.

Sixth.—The contractor will feel during the progress of the construction that the client is a partner on the job, and that, therefore, he and his engineers will not be likely to be unnecessarily severe in their requirements, also that they will permit the adoption of all legitimate expense-saving expedients, and will not demand too many frills on the finishing.

Seventh.—Owing to the justice and equity involved by this method of contract-letting and profit-sharing, all concerned in the execution of the work will labor whole-heartedly and good-naturedly, avoiding petty squabbles and disagreements of all kinds; and the result will be earnest, honest effort, a satisfactory piece of construction, and the general contentment of both parties to the agreement.

Adoption of Method

If this proposed method of contract-letting and profit-sharing be received with favor by engineers, architects, contractors and builders in general, it could easily be adopted as a standard for the country by calling a small convention with a single representative from each of the leading technical and railroad societies, contracting organizations, and bankers' associations, to discuss the advisability of adopting it (or else some slight modification of it) and to report the decision of the meeting to the said bodies for their approval. If any large group of clients, such as the railroad companies, were to adopt the method as standard and use it, very soon everybody having construction contracts to let would follow their example, thus making it the universal standard of contract-letting for our country—nor would it be long before other American countries would follow our lead, thus greatly simplifying our business relations with the various American commonwealths.—From "Contracting," of Chicago.

The Asphalt Association has opened a branch, or district, office in Washington, D.C., in charge of Maj. Harry D. Williar, formerly of the Maryland Road Commission and later with the Paving Commission of Baltimore.

The following resolution was adopted last month at the Canadian Mining Institute's convention in Vancouver: "That the formation of a Canadian Association of Engineers, for the purposes of social service, mutual protection and legislation is desirable and in the best interests of the public and of the profession."

The directors of the Engineers' Club, Toronto, have decided to increase the entrance fee from $50 to $100, effective January 1st. All applications received this month will be subject to the former rate. The directors announce that they have no intention at the present time of increasing the present annual dues.

The annual election of officers of the Toronto branch of the Engineering Institute of Canada was held last Thursday night at the Engineers' Club, Toronto, with the following results: R. O. Wynne-Roberts, chairman; executive committee—Geo. T. Clark, Thos. Taylor, Prof. C. R. Young and J. C. Krumm. W. S. Harvey was re-elected secretary, but as he has moved to the United States, his successor will be appointed by the executive committee. The new officers will assume office about January 20th, 1920.

THE RAILWAY SITUATION IN CANADA TO-DAY

WILLIAM FRANCIS TYE, formerly chief engineer of the Canadian Pacific Railway, addressed the Montreal branch of the Engineering Institute of Canada last Thursday, the title of his address being "The Railway Situation in Canada To-day."

Transportation, said Mr. Tye, is a more important question in Canada than in any other part of the world on account of its geographical position. The Dominion is divided into an eastern area, comprising Ontario, Quebec and the maritime provinces, and a western area including Manitoba, Saskatchewan, Alberta and British Columbia, the two areas being separated by long stretches of barren territory. In the west the products are mainly agricultural, which have to be transported east, whilst the manufacturing products of the east are carried to the western provinces.

Government Has Always Helped

There are 39,000 miles of railroad in Canada, giving one mile to every two hundred people. This is practically equal to Germany with her 75 million population, to India with 330 million, and nearly as much as Russia with 170 million. The rates are low, considerably lower than those obtaining in the United States, and the service is good.

From very early days the Federal government has always helped the railways. The first assistance was a grant of $35,000,000 and 18,000,000 acres of land given to the Canadian Pacific. Subsequently, the grant became 3,200 acres per mile for cheaper lines and 6,400 acres per mile for those lines which cost more than $15,000 per mile to build. The third scheme conceived was the issuing of guarantee bonds, which was done on the theory that the guarantee would never be called upon, but the liability has proved to be tremendous. The guarantee on parallel lines, which was given later, appears to have been especially disastrous.

Why have the railways failed? asked Mr. Tye.

In 1906, all privately owned roads were prosperous; the C.P.R. and G.T.R. were rich, and the C.N.R., though not paying dividends, was doing well. Now the C.N.R. and G.T.R. are bankrupt, and only occasionally in late years have they earned the cost of operation of their roads.

There has been keen rivalry as to which should become the second transcontinental railway. Bond guarantees given by a liberal government enabled the G.T.R. to build 3,900 miles of main and 1,200 miles of side lines. Similar guarantees by a conservative government assisted the C.N.R. to extend their system from 2,000 to 10,000 miles. This rapid construction, and the way in which it has been carried out, has resulted in the bankruptcy of both railroads.

It has been said that "Railroads were opened first and built afterwards, i.e., in advance of civilization." This meant light revenues, and, of necessity, light expenses. Steep grades, few turnings, light rails, few terminals are necessary in building a new line in virgin territory. As the revenue increases, steam shovels can be employed to make big cuts and fills at a smaller cost than would have been incurred by using light equipment, new depots and sidetracks can be constructed, and the road can be made a good one. Heavy expenditure of money in the early stages of development is not justified, as the interest amounts to large sums. At 5% money doubles itself in fourteen years.

G.T.P. Too Expensive Construction

The Grand Trunk has always been accustomed to deal with the east, with Ontario, the United States, etc., having immense traffic, and there has always been need of heavier rails, more sidetracks, and more terminals to take care of this traffic. In expanding in the west, they have built a very expensive line, giving a fine road, with better grades than those obtained on the C.P.R., but their revenue has been insufficient to pay operating expenses and fixed charges. The parent company in the east have been getting into difficulties, and finally have had to give up the western line.

The Canadian Northern have a good western line, which has been paying well, but, desiring to become transcontinental, it has built east to a country already well served with railroads. To do so, it has had to parallel other roads to Montreal and Toronto, and has found it very costly to obtain proper terminals. The C.N.R. has a small yard in Montreal, but no freight yard, while the C.P.R. has some fifteen to twenty freight terminals in the city. The C.N.R. cannot hope to compete, as the public will not haul freight a long distance in order to reach a yard.

The C.N.R. commenced by buying old, poor-paying roads in Ontario and Quebec. The company have built north from Toronto, and, where a single track would suffice, there are now three roads; it parallels the G.T.R. from Toronto to Kingston. The C.P.R. also covers this area, and there exist one double and two single tracks, when one double track is amply sufficient to take care of the traffic. It has been proved that there is not enough traffic on the expensive line in Ontario, and the company has become bankrupt.

G.T.R. and C.N.R. Mistakes

The mistake of the G.T.R. has been the building of a main line in the west, which was not justifiable, and that of the C.N.R. the extension of its line east to traffic centres already occupied.

There would be no railway problem to-day had the government adopted a policy of this nature in dealing with these railroads: "The G.T.R. has a good eastern road, the C.N.R. the beginnings of a good western road. Let them get together and connect their roads. We will give money to assist them in carrying this out, and later, in developing their line to the Pacific Coast." Instead of this, the government aided the roads in parallel.

If the solution some years ago had been consolidation, still more is that the case now, with the extra roads in Northern Ontario. Another reason which has an important bearing on this question is the future return of the railroads to private ownership. The lines must be prosperous before any company will consider taking them over, and if the lines were consolidated, they would be in good physical condition. It is the best system in the east, with the G.T.R., C.N.R. and other government lines, and is very good in the west. It has the shortest line from Winnipeg to Toronto and Montreal, good grades, reasonable curves, and the easiest route across the mountains.

The railways are in a very unfortunate position financially. Statistics for the year ending June 30th, 1918, give the following data:—

Loss on old government railways	$ 5,800,000
Loss on C.N.R.	11,675,000
Loss on G.T.R. and subsidiaries	10,250,000
Total losses	$27,725,000

The interest on the Intercolonial at 4% and on the Transcontinental at 3% amounts to $11,000,000, giving a total of losses and interest payments of $39,000,000.

Summing up costs of government railroads, and figuring interest on these at another $11,000,000, the absolute total reaches a figure of $50,000,000. The net earnings for the year 1918 of the C.P.R., acknowledged to be one of the most successful railways, amounted to $34,500,000. The other railroads have to face a possible yearly deficit of $50,000,000—one and one-half times the earnings of the C.P.R.—and the problem to-day requiring solution is, How are they to continue and be made prosperous?

Must Increase Freight Rates

"First," continued Mr. Tye, "give an immediate and decided increase in freight rates. This will have a very slight effect on the cost of living. The cost of transportation in Canada is very cheap, indeed, and, compared with Australia, the rates in Canada are about one-third those obtaining in that country."

Reference was made by Mr. Tye to an article on "The Railway Problem," by C. W. Baker, published October 23rd, 1919, in the Engineering News-Record, of New York, in which a table was given showing the increase in cost price of an article when freight rates are increased 50%. This table is reprinted herewith.

It is admitted that an appreciable increase does occur on such articles as coal and grain where transportation forms a large part of the final cost, but in the case of clothing, shoes, sugar, butter, fresh meat, etc., if the freight rates are raised 50%, nobody would notice the subsequent difference in cost. Therefore, the first step towards a solution is to raise freight rates, independent of the fact whether the railroads are run by private or government management.

The second step towards solution is to decide whether the railroads shall be privately owned or owned by the government. Mr. Tye stated he knew of no railroad which was successful under government management except in Germany, and the success there was due to the reasons that the roads were built for a large population; that they were not run as commercial enterprises, but solely for war domination; and that the workers were employees of the state, and as such could not strike.

The Intercolonial had as much business per mile as the C.P.R., yet it had never earned interest, and only for two or three years has it earned sufficient money to pay operating expenses. Sir Henry Drayton and Mr. Ackworth, who were members of the Royal Commission appointed to inquire into the railway question, have stated. "We know of no democratic state where the railways are owned by the government but where politics have a large bearing on the railways and the railways a large bearing on politics." No man works for a government as well as he will for a private concern. The margin between success and failure is very slight, and this has been emphasized by Lord Shaughnessy in a speech delivered about a year ago. C.P.R shareholders paid $112 for $100 worth of common stock, and $31 was added from sur-

How a 50% Increase in Freight Rates From Marketing Centres to Consuming Centres in U.S.A. Would Affect Cost of Products

Refined oil, Tulsa, Okla., to Cleveland, 960 miles, rate 38.5c. per 100 lbs. An increase of 50% would mean 1.3c. per gallon.

Fresh meat, Kansas City to Pittsburgh, 898 miles, rate 52c. per 100 lbs. An increase of 50% would mean ¼c. per lb.

Cattle, Dallas to Kansas City, 484 miles, rate 33.5c. per 100 lbs. An increase of 50% would mean 1/6c. per lb.

Potatoes, Houlton, Me., to New York City, 567 miles, rate 30c. per 100 lbs. An increase of 50% would mean 8c. per bushel.

Lumber, Winona, Miss., to Philadelphia, 1,160 miles, rate 33c. per 100 lbs. An increase of 50% would mean 5.37c. per 1,000 ft.

Oranges, Palatka, Fla., to Pittsburgh, 1,121 miles, rate 62c.* per 100 lbs. An increase of 50% would mean 31c. per crate.

Grain, Fargo, N.D., to Chicago, 640 miles, rate 18.5c. per 100 lbs. An increase of 50% would mean 4.6c. per bushel.

Grain products, Chicago to Baltimore, 749 miles, rate 19.5c. per 100 lbs. An increase of 50% would mean 9.7c. per 100 lbs.

Butter, St. Albans, Vt., to Boston, 315 miles, rate 65c.* per 100 lbs. An increase of 50% would mean ½c. per lb.

Anthracite coal, Carbondale, Penn., to Springfield, Mass., 308 miles, rate $2.75 per gross ton. An increase of 50% would mean $1.23 per net ton.

Bituminous coal, Cresson, Pa., to Chatham, N.Y., 476 miles, rate $2.40 per gross ton. An increase of 50% would mean $1.07 per net ton.

Iron ore, Ashtabula, Ohio, to Latrobe, Penn., 170 miles, rate 93c. per gross ton. An increase of 50% would mean 46c. per gross ton.

* Rates in effect January 1st, 1919.

plus revenue, making $143 for a $100 share. Last Wednesday's quotation was $138. Seven per cent., which is the highest dividend paid on railway stock, only amounts to 2¼% on the cost of the railway system, or, taking the dividend at 10%, which includes interest on other branches of the company's affairs, the amount is 2½% on the total of the company's assets. In 1895 the company paid no dividend; in 1897, 2½%; in 1901, 4%; in 1904, 6%, and only in 1907, twenty-six years after formation, was the maximum dividend of 7% reached.

The difference between government and private operation is very large, and it is difficult to realize how government operation, pure and simple, can ever be a success. Drayton and Ackworth had proposed that a company, named the Dominion Railway, be formed, with the stock vested in the company, and managed by a self-perpetuating board of men unattached to any government Mr. Tye did not think there was enough difference between this arrangement and pure government operation to make it a success. One parliament cannot prevent another parliament following it from making changes, and the dangers inherent to government operation are inherent to this system also.

Government operation has been tried in the United States for two years, but the public are now clamoring that the railroads be turned back to private ownership. The only solution for Canadian railroads is to return them also to private owners, making compensation for the irreparable damage done to the roads by government operation. A new company should be organized to take the roads over as private concerns. Possibly the government would have to aid the private companies, but that would be better than a deficit every year. The solution of Canada's railway problem, Mr. Tye claimed, is (1) Increase the freight rates; and (2) return the railroads to private ownership.

ENGINEERING INSTITUTE ELECTIONS

At a meeting of the Engineering Institute of Canada held November 25th in Montreal, the following elections and transfers were announced:—

Members.—P. L. Allison, Peterboro, Ont.; C. W. Dill, Regina, Sask.; G. R. Langley, Peterboro, Ont.; W. R. MacDonald, St. Catharines, Ont.; W. O. Marble, Vancouver, B.C.; J. W. Morrison, Dane, Ont.; P. B. Roberts, London, Eng.; E. R. Shirley, Peterboro, Ont.; C. E. Sisson, Peterboro, Ont.; C. W. Tarr, Windsor, Ont.; P. P. Westbye, Peterboro, Ont.

Associate Members.—G. B. Anderson, Ottawa, Ont.; Capt. B. L. Barns, Peterboro, Ont.; C. B. Bate, Ottawa, Ont.; C. H. Blanchard, Winnipeg, Man.; A. F. Bookhout, Peterboro, Ont.; J. S. Brisbane, Montreal East, Que.; Lieut. C. F. Corbett, Cardston, Alta.; W. F. Coutlee, Ottawa, Ont.; John Craig, Nelson, B.C.; J. W. Crashley, Toronto, Ont.; J. B. Croly, Vancouver, B.C.; S. L. Decarteret, La Tuque, Que.; Maj. Philip Earnshaw, Toronto, Ont.; Lieut. W. J. Fletcher, Windsor, Ont.; Maj. J. H. Forbes, Smith's Falls, Ont.; C. A. De W. Fowler, Armdale, N.S.; A. B. Gates, Peterboro, Ont.; T. E. Gilchrist, Peterboro, Ont.; A. J. Gray, Toronto, Ont.; Capt. E. K. Hall, Edmonton, Alta.; P. C. B. Hervey, Edmonton, Alta.; S. A. Lanzon, Toronto, Ont.; J. O. Martineau, Quebec, Que.; D. L. McLaren, Peterboro, Ont.; H. T. Melling, Regina, Sask.; Lieut. F. H. Palmer, Halifax, N.S.; Lieut. W. G. Perks, Peterboro, Ont.; W. J. Pickrell, St. John, N.B.; Lieut. G. C. Reid, Cobalt, Ont.; Charles Robertson, Peterboro, Ont.; Capt. H. L. Roblin, Red Deer, Alta.; N. D. Seaton, Peterboro, Ont.; C. V. Stout, Winnipeg, Man.; A. L. Sutherland, Peterboro, Ont.; H. H. Tripp, Edmonton, Alta.; A. S. Weekes, Edmonton, Alta.; George Blanchard, Port Arthur, Ont.; T. M. Jones, Toronto, Ont.; S. S. Kennedy, Winnipeg, Man.; S. D. H. Pope, Victoria, B.C.; J. A. W. Waring, St. John, N.B.

Associate.—G. C. McAvity, St. John, N.B.

Juniors.—C. T. Evans, Windsor, Ont.; R. E. Hinton, Peterboro, Ont.; E. L. Holmgren, Peterboro, Ont.; Lieut. H. A. Lynch, Ottawa, Ont.; R. D. McKenzie, Winnipeg, Man.; J. F. Patterson, Montreal, Que.; J. H. Reid, Peterboro, Ont.; L. De B. Roy, Ottawa, Ont.; C. B. Shaw, Hawkesbury, Ont.; R. E. Stavert, Peterboro, Ont.; Lieut. D. C. Wills, St. Catharines, Ont.; Maurice Cossette, Montreal, Que.; J. E. Lyon, Ottawa, Ont.; Stewart Schofield, Winnipeg, Man.; Capt. R. D. Thexton, Ottawa, Ont.

Transferred, Associate Members to Members.—J. N. Finlayson, Winnipeg, Man.; S. J. Fisher, Montreal, Que.; A. R. Greig, Saskatoon, Sask.; G. H. Herriot, Winnipeg, Man.; Maj.-Gen. G. B. Hughes, Derby, Eng.; Maj. W. G. Swan, Vernon, B.C.; F. B. Tapley, Moncton, N.B.

Transferred, Juniors to Associate Members.—Capt. F. X. Amos, Corinth, Ont.; Lieut.-Col. D. S. Ellis, Kingston, Ont.; J. M. Gibson, Toronto, Ont.; F. H. Hibbard, Sherbrooke, Que.; Lieut. S. E. McColl, Winnipeg, Man.; Ernest Peden, Montreal West, Que.; Maj. G. R. Taylor, Grafton, Ont.; E. E. Wells, Toronto, Ont.; Capt. Walter Youngman, Winnipeg, Man.; J. N. Aggiman, Port Alfred, Que.; G. M. Hudson, Montreal, Que.; B. L. Nares, Montreal, Que.; P. O. Spicer, London, Eng.

Transferred, Students to Associate Members.—Capt. A. L. Cavanagh, Winnipeg, Man.; L. G. McNeice, Wallaceburg, Ont.; Charles Bruce, Ottawa, Ont.; E. V. Gage, Montreal, Que.; E. P. Muntz, St. Catharines, Ont.; E. S. Smyth, Kitchener, Ont.

Transferred, Students to Juniors.—H. H. B. Loignon, Outremont, Que.; J. A. Vance, Woodstock, Ont.; A. P. Black, Toronto, Ont.

TOWN PLANNING IN RELATION TO INDUSTRIAL DEVELOPMENT

(Continued from page 525)

city. There is no denying the presence of certain flies in the ointment, so to speak, from a town planning viewpoint, but to those who have witnessed it, I think the view from the mountain top bears out the claim I have made—that it is possible so to plan a city that it may be an industrial centre and at the same time an attractive residential city. Were it possible to go back to the beginning, I would say that, looked at from the viewpoint of both manufacturer and the dweller, it would be advisable to set apart industrial areas wherein no dwelling should be built, and residential districts the doors of which would ever remain closed to industrial and commercial enterprises, but just how far town planners should be permitted to go in disturbing existing conditions, I am not prepared to say. I can see how they might easily defeat what I understand to be their aims—the development and betterment of the community.

What I have already said has dealt almost entirely with houses and workingmen. Before I close, let me suggest that town planning should, if it does not now do so, give quite as careful consideration to the laying out of the industrial areas as it gives to the residential sections. If a city desires new industries, or if it wants to see its existing industries prosper and expand, it must provide them with the proper facilities for doing business. In every city that I know of, heretofore when a new industry came along it was permitted to acquire a tract of land and locate its buildings regardless of what effect its actions would have on the industrial development of adjacent lands. The result is that we have more railway switches crossing the streets than would have been necessary had the industrial areas been properly planned in advance, while in some cases large tracts of land otherwise suitable for industrial purposes have been cut off from railway connections altogether, rendering them unsuited for factory uses, while they are practically useless for other purposes. These are conditions that exist right here in Hamilton, and to my knowledge in some other Canadian cities.

Care should also be given to the laying out of the streets in industrial districts. They should be so arranged as to lead to the commercial and residential districts by the shortest possible routes consistent with good town planning and the general scheme for the development of the community, for it is important that it should be made as easy as possible for the working people to get from the factory to their homes and from their homes to the factory, and it is equally important that the manufacturer should be able to

deliver his finished products as quickly as possible to the railway freight sheds or local distributors.

On the extent and nature of the town planning of to-day, to a very large measure depends the extent and nature of the future industrial development of every industrial centre. It would not be difficult to show that the industrial development of to-day has been very greatly influenced by the happenings of years ago. And so it will be always. Town planning and industrial development are very closely related.

THE FUTURE DEVELOPMENT OF THE SOUTH SHORE OF THE ST. LAWRENCE RIVER, OPPOSITE THE CITY OF MONTREAL

INCLUDED in the proposals of the Harbor Commissioners of Montreal for the development of Montreal Harbor is a bridge spanning the St. Lawrence river from the docks to a point on the south shore, crossing St. Helen's Island in midstream.

Ernest Drinkwater, consulting engineer, Montreal, in a report to the South Shore Board of Trade, comments on the present stagnation of the municipalities located on the south shore, owing to lack of transportation facilities, and strongly urges the commencement of work on this bridge, in order to provide labor to many grades of workmen now unemployed, and to assist in the development of the south shore territory. It will be noticed from the sketch that Mr. Drinkwater suggests that the southern half of the bridge be diverted to a point approximately 600 ft. down the river. Subsequent to the date of the first plan of the proposed bridge, the Harbor Commissioners have secured control over some 60 acres of property, 4,100 ft. long by 700 ft. in depth, which consists of the whole of the river frontage of the ordnance lands of the federal government. The suggested diversion gives direct access to this land, and unless the change is made, the railroad traffic will have to switch back in order to get to the river from; and that this will entail considerable interference with the proposed civic development of the south shore, is claimed by Mr. Drinkwater.

It will be observed that the Quebec, Montreal and Southern Railway and the old Grand Trunk and South Eastern Railways, whose rights of way are still available for use, can very conveniently connect with the proposed location. It is the earnest desire of those interested in the natural development of the south shore, to keep the railways on the river front as far as possible, and within those areas which will be reserved for the suggested future improvement of the south-east side of Montreal Harbor. Following is an abstract of portions of Mr. Drinkwater's report:—

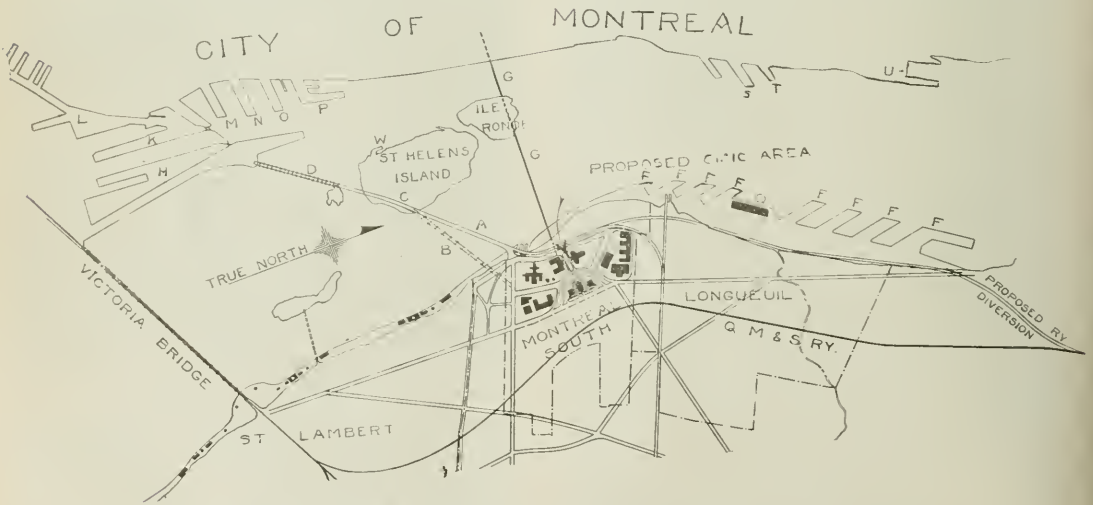
This bridge should be of sufficient width to give passage for all the public services, such as railways, tramways, driveway and footpath, electrical conductors, telephone wires and gas mains, and being built by public money, the public should be given the utmost service therefrom. Having more than a local importance, there should be organized immediately a board of engineers to direct the construction in conjunction with the Harbor Commissioners.

The condition of the south shore to-day shows that its development has been strangled by the lack of proper transportation facilities, and the exorbitant tolls charged over the Victoria Bridge by the Grand Trunk Railway. In addition to the steam railway track, this bridge only permits a single line suburban tramway service, a 3-ft. sidewalk and a 14-ft. driveway.

Vehicles must pass over the steam tracks in order to gain access to the driveway, and vehicular traffic suffers considerable delay owing to the heavy through traffic and shunting. The narrow width of this driveway is responsible for damages (from overhanging loads of other vehicles) often incurred by motor cars.

One of the objectionable tolls to be paid by the people on the south shore is $100 per year for a telephone wire passing over the mile and a quarter of bridge. This is an extra paid by the customer in addition to the service.

While these conditions exist, it is hardly possible that any general development can take place, and it is questionable if there is a parallel to this situation in any part of the world; that is to say, a district with so small a population, opposite a city approaching a million inhabitants, at the head of navigation of one of the largest rivers in the world, which has an ever-growing traffic. The whole of this district has a population of only about 12,000, with absolutely no harbor development and less river front activity than existed 70 years ago. Thirty millions have been spent to develop the Montreal side of the harbor during this period, and practically not a cent on the south shore. Seventy years ago there were three railways serving Montreal which had their terminal points on the south shore. On the building of the Victoria Bridge, the three lines were brought together, and taken over this bridge to the Island



PLAN OF MONTREAL HARBOR AND SOUTH SHORE, INDICATING SUGGESTED IMPROVEMENTS

B, C, D, Location for new bridge proposed by Harbor Commissioners; A, diversion proposed by South Shore municipalities; F, proposed docks; G, proposed tunnel (to Montreal central terminal); H, basin for inland and coasting vessels; K, Windmill Point basin; L, Lachine canal; M, N, O, P, S, T, docks; U, Vickers dry dock and shipbuilding plant; W, concrete ferry-wharf.

of Montreal. The south shore lost the advantage of these terminals, and thus the Victoria Bridge performed a two-fold purpose,—but to the detriment of the south shore.

The proposed new bridge will fulfil many functions for the general benefit of all. For the railways, it can be the means of connecting the two systems of the National Railways of Canada. The Canadian Northern section from the Mount Royal tunnel can pass over this bridge and join the Intercolonial system, the G.T.R. line to Portland the Central Vermont and the Quebec, Montreal and Southern Railway (D. & H.). All these railways could reach the business section of the city of Montreal and save a distance of five to seven miles, by making use of this bridge. The bridge would give the National, Transcontinental and Canadian Northern access to the United States, without having to go to the Quebec Bridge and come back to St. Hyacinthe, some 250 miles, and there is no doubt that the saving, to the Government railway alone, would go a long way towards payment of the cost of the bridge. To the city of Montreal it would reduce the delay on the many street crossings between Bonaventure and St. Henry.

The south shore is waiting to receive the suburban tramways service it requires in order to develop, as the distance to the centre of the populated area would be reached in seven to eight minutes from the foot of McGill St.

The people of the city of Montreal, and of the south shore, would have access every day of the year to the beautiful park in the centre of the river (St. Helen's Island), by tramway in a run of five minutes. This would save the city many thousands a year now paid for ferry service. The driveway would give vehicular traffic an entrance to the city of Montreal that would be a credit to the city and province, and obviate the present route, which the tourist traffic from the United States and the intervening part of the province have to follow to get into the city. The bridge could carry many public utilities to the advantage of the city of Montreal and the south shore.

Town Planning Needed Now

With the building of this bridge, there should be enforced upon the south municipalities a definite plan of development, as within two miles of the debouching point of this bridge, there are five municipalities, each composed of various subdivisions laid out without any regard to their neighbors, much less to the lines of communication with the adjoining municipality. There is only one direct means of communication between these municipalities, and that is the River road, which is impassable in the winter time, and, at the present time, this is the only road communicating with the site of the proposed bridge.

It is of urgent necessity that the South Shore Board of Trade should proceed with the proposition for the formation of the Town Planning Commission, in order to lay out the lines and method of rational development of the future city on the south shore. If this cannot be brought about by amalgamation, then the provincial authorities should step in and deal with the matter, as the present situation is impossible. Only one of the towns is zoned for trade, commerce and dwelling areas, and the lack of proper building regulations for the protection of the health and property of the residents exists in most parts of the district.

For the benefit of the towns themselves, and the province generally, it is urgent that immediate action be taken, before any general development occurs on the present lines of the layout of the district. If this is not done, it will cost millions in the future to do what can be better done for thousands now.

Suggested Civic Centre

With the amalgamation of these municipalities there is a site for a civic centre on the south shore end of the bridge, second to none in the Dominion. This property is owned by the Department of Militia and Defence, and has been lying idle for upwards of half a century. It has a frontage on the river of three-quarters of a mile, and an area of about 170 acres. In addition to having the largest frontage on the river of any lot in the county of Chambly, it is also one of the highest standing properties, considering its depth from the river, and on it could be grouped the city hall, court house, library, art gallery, hospital, market, armory and customs house. The whole could be given a setting that would compare favorably with the departmental buildings at Ottawa. The carrying out of a scheme as outlined and the construction of the bridge would assist in placing before the public a residential district, within a few minutes of the centre of the city of Montreal, which would have the added advantages of the country and a waterfront.

Dyke and Boulevard

If the federal government is desirous of finding work for the unemployed, there is no work that could be started of a more useful nature than on the bridge according to the adopted plans of the Harbor Commissioners. The building of this bridge will necessitate the opening of a channel, averaging approximately 2,000 ft. wide, and probably 18 ft. deep, and which is estimated to contain nearly 15 million cubic yards of material to be excavated. Half of this would build a dyke and boulevard, and form flood protection work 300 ft. wide from the Laprairie Dyke to the proposed new bridge. This material could be utilized to provide a magnificent boulevard, with areas reserved for all recreation purposes, at very little cost, as the dredging will have to be done, and the dyke is a necessity.

Opportunity for New Elevator

It has been stated that there is need in the harbor for another grain elevator, where railway cars, lake and inland navigation boats could be unloaded, and, at the same time, where ocean-going tramp and other ships could be loaded with grain in a few hours. With the railway facilities which will be available when the bridge is constructed, there is a splendid opportunity for the Harbor Commissioners to start the development of the hitherto neglected south shore by building a record-beating grain elevator of, say, ten million bushels. (See Q on sketch.) The Railway Board might consider commencing the work of preparing the existing rights of way and approaches to the new bridge. These are now available. On the development of a general city planning scheme, assistance might be received from the Provincial Department of Municipal Affairs to carry out some of the work of urgent necessity.

At a meeting of the Peterborough branch of the Engineering Institute of Canada, held last Saturday, the following officers were elected for the coming year: Honorary chairman, R. B. Rogers; chairman, Reid Munro, sales manager of the William Hamilton Co., Ltd.; vice-chairman, R. H. Parsons, city engineer; secretary, R. L. Dobbin, water works engineer; treasurer, D. L. McLaren; executive committee—E. R. Shirley, A. L. Killaly, G. R. Langely, C. E. Sisson, P. L. Allison and P. P. Westbye.

The people of the Border Cities in Ontario voted last Saturday to purchase the Sandwich, Windsor & Amherstburg railway from the Detriot United Railway, and to place it in the hands of the Hydro-Electric Power Commission of Ontario for operation and maintenance. In an interview with Sir Adam Beck last Monday at London, Ont., the "Hydro" chief pointed out that of the $23,000,000 involved in the proposed purchase of certain electric railway lines which will form the beginning of the Hydro-radial system of Ontario, the people have voted to buy or build more than $17,000,000 worth. Those which the people have voted for to date include the Toronto to St. Catharines line via Port Credit and Hamilton; the Welland and Bridgeburg line; the Toronto and Northeastern; and the Sandwich, Windsor & Amherstburg railway. The lines yet to be voted upon include the Toronto & Bowmanville railway and the line from Hamilton to Galt, Guelph and Elmira. The Sandwich, Windsor & Amherstburg railway will be the first radial to be operated by the Hydro commission, although a commission of which Sir Adam Beck is chairman and which is appointed by the London city council, operates the London & Port Stanley railway.

PIECE-WORK SYSTEM IN METER READING*

By J. A. A. Beaudin
Of Montreal Light, Heat & Power Consolidated

THE supply of public utilities involves the performance of numerous routine operations in the consumer's home by various categories of employees operating individually and without supervision.

The reading of meters in situ, the delivery of bills and collection notices, and the collection of arrears are a few of these operations.

Until recent years, and even nowadays, the general practice has been to remunerate employees engaged in these various tasks on a flat or fixed rate salary, based either on the hour, day, week or month, with additional privileges (in many cases) respecting sickness, holidays, etc.

Salaried Worker Leaves No Residue

This mode of remuneration makes possible the payment of wages for labor which has been only partially supplied, and since the actual supervision of his work is impracticable, the employee is tempted to take advantage of this condition occasionally, if not regularly, to limit his activities, and the means he may use to conceal his shortcomings are only limited by his ingenuity and his morality.

Furthermore, an employee working under this system of remuneration is inclined to complete indiscriminately each task as he encounters it, without any regard whatever to the amount of time and expense involved—i.e., he will often devote an unwarranted amount of time to straightening out a difficulty which if reported to the office could be handled much more expeditiously and economically by an expert. In other words, a worker on a fixed salary does not by-pass difficulties—he leaves no residue.

Piece-Worker Leaves a Residue

This state of affairs has led our company to devise and introduce a system of payment on a piece or commission basis as applicable to the various categories of these employees. This piece-work or commission system keeps the employee at his work, insures the full employment of his time, limits his absences from duty, prevents the payment of unearned wages, and regularizes the output—it helps get the work done regularly and systematically, but it leaves a residue.

The piece or commission worker is interested in handling a maximum of cases in a minimum of time, so naturally the tendency is to handle the straight-going jobs and by-pass difficulties whenever encountered, no matter what the employer's interest; the employee's interest is in the opposite direction, as every stop he makes to overcome difficulties limits his wages, hence while this system has removed the necessity for outdoor supervision, it has created a demand for closer indoor supervision over the work performed, and the piece-work system must be supplemented by a faithful follow-up system of by-passed jobs, without which it would prove a failure and cease to be economical and practical.

Workers Exchange Districts

The piece-work system only works advantageously in districts where the clientele is dense or semi-dense; it is not effective in districts where the clientele is scattered. The piece-worker is entitled to a supply of work commensurate with his capacity, and his work requires to be properly sorted and routed so that he may carry it on under advantageous conditions. The employer's interest also demands this in order to keep the piece-work rating at a minimum and at the same time afford the employee an opportunity of earning a fair remuneration thereunder. Failure to give proper attention to this detail would result in the establishment of a higher piece-work rating than would otherwise be necessary.

*Excerpt from paper read at the last annual meeting of the Canadian Gas Association.

Employees of the same category should all be on an equal footing and be given equal opportunities. They should permute periodically from one district to another in order that one and all may cover each district and the entire system in a given period. All districts do not afford similar or equal opportunities and no one should be allowed to work continuously in either a good, poor or medium district, but all should have their turn in each.

Activities Cannot be Limited

The piece-worker, although not a tracer, a trouble straightener or a worker fitted to operate in scattered districts, must be efficient and capable of discharging his duties in a competent manner and carrying to a satisfactory conclusion all work entrusted to his care. While he is quite within his rights in by-passing real difficulties and not spending his time in conducting long searches, etc., he must positively not be allowed to by-pass for trifling causes any of the work entrusted to him.

It is not desirable to limit the activities of a piece-worker with a view to securing work of a higher standard, as he cannot fairly be retained in service without sufficient work to keep him employed, and even if allowed to go off duty as soon as he has performed his limited task, he will work just as hastily in order to get through and go off duty, and the employer's very object—viz., to cause him to move more slowly and perform work of a better quality, will be defeated; furthermore, the resultant limitation of his earning power is likely to cause the piece-work rating to go up. An energetic piece-worker with a large working capacity will earn "record" wages when supplied with unlimited work and will indirectly contribute to the maintenance of an economical and moderate piece-work rating. Furthermore, the employee who earns large wages will have every inclination to perform his work in accordance with instructions—his very interest in his position is the best guarantee to be wished for in this connection. A proper inside supervision over the work involved in the completion of by-passed jobs, as reported by the piece-worker from time to time, affords the employer a still further protection. This inside supervision is a most important feature of the piece-work system and must be exercised with constant vigilance.

Having now dealt with the economic aspects of the piece-work system, it may be of interest to outline briefly its operation in our company, especially as applied to our meter readers.

Saturday Devoted to "Pick-Ups"

We supply "dual service" (gas and electricity) and issue part of our bills on a bi-monthly basis and part on a monthly basis. The ordinary gas and electric lighting consumers are billed bi-monthly, while the larger consumers and all electric power users are billed monthly. Our territory is divided into meter reading districts and the work distributed in accordance with schedules, so that the readings repeat themselves on about an even calendar date in each district. Twenty-two men take care of our meter reading on a piece rating per meter. These men work five days per week on regular readings; every Saturday morning is devoted to each man "picking-up" the readings which he has by-passed for various reasons during the current week. This "picking-up" work is done at the regular rating for current readings. After the completion of this "picking-up," the residue of by-passed readings reported to the office represents only such cases as present unusual obstacles. The fact that each meter reader must appropriate a certain amount of time to "picking-up" his own by-passed readings is an added protection against by-passing for trifling causes. When reading meters in a district where the clientele is scattered, the meter readers are paid an additional flat rate sum per district; this rate varies from 50c. to $2.00 per meter book. A somewhat similar system is in vogue in connection with power and special clients billed monthly, as such customers are limited in number and distributed all over the system. In addition to the regular staff two special meter readers are also employed on a combined fixed salary and piece-work basis to take care of readings by-passed by the regular readers.

"CLOSING" THE PROFESSION IN ENGLAND

IN view of the fact that the Engineering Institute of Canada and the Joint Committee of Technical Organizations have recently drafted proposed legislation defining the status of the engineer in Canada, it is of interest to note that a Bill will be introduced in the next session of the British House of Commons to regulate and to establish registration for the civil engineering profession. The principal provisions of the Bill are as follows:—

By "civil engineer" is meant a person competent in the art described in the Royal Charter of the Institution of Civil Engineers of 1828 and its subsequent development through the advance of science. The definition of the profession of civil engineering is generally attributed to Thomas Telford, the first president of the institution, and reads as follows:—

"The art of directing the great sources of power in nature for the use and convenience of man, as the means of production and of traffic in states both for external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation and docks for internal intercourse and exchange, and in the construction of ports, harbors, moles, breakwaters and lighthouses, and in the art of navigation by artificial power for the purposes of commerce, and in the construction and adoption of machinery, and in the drainage of cities and towns."

The register as first established would contain: (a) All corporate members of the Institution of Civil Engineers and of the Institution of Civil Engineers in Ireland; and (b) other persons who are engaged as civil engineers and are members of important engineering societies; or who, although not members of such societies, have been engaged in civil engineering practice for a substantial period.

It is proposed that there be a time limit for the application of these conditions to the formation of the register. For the purpose of determining the elegibility of engineers in the second group, a tribunal is to be established upon which the important engineering societies are to be represented, and by means of which the interests of their members who are civil engineers will be safeguarded.

ECONOMICS OF PLACING CONCRETE

MOST engineers agree that in order to use concrete towers and spout the mixed materials long distances, the mixture must be wetter than good practice would dictate. The work of Professor Abrams at the Lewis Institute, Chicago, has brought to the attention of the engineering profession more sharply than ever before the harmful effect of excessive water upon the strength of concrete. It is generally conceded that in order to use towers, from 30% to 50% more water must be used than if the materials are placed by other means. With this in mind, owing to the detrimental effect of too much water upon the strength of concrete, several construction companies have practically tabooed the use of towers.

Engineering opinion appears to have been modified somewhat upon this point during the past year, however, and it is becoming more clearly recognized that the whole problem is one of economy, and that towers are justifiable if by their use money can be saved in placing the concrete, provided that the proper cement-water ratio is adhered to at all times. Many engineers to-day are saying to their contractors:—

"Use towers if you wish, but you must keep the cement-water ratio constant. When you add more water in order to use your chutes, you must add sufficient extra cement to maintain the same cement-water ratio. If the use of your towers saves you more money than the extra cement costs, you are wise to use towers; but if the cost of extra cement is much greater than the additional cost of getting the concrete into the forms in some other way, it would pay you to abandon your towers."

PERSONALS

J. G. SULLIVAN, consulting engineer, Winnipeg, has been elected as a member of the Winnipeg city council.

C. F. GRAY, electrical engineer, Winnipeg, Man., has been re-elected mayor of that city by more than 2,500 majority.

SIR ADAM BECK, chairman of the Hydro-Electric Power Commission of Ontario, expects to sail on Saturday next for England, on personal business.

J. M. STEVENSON, of Calgary, who recently returned from overseas, has been appointed resident architect at that city for the Public Works Department of the Dominion government.

HON. LIONEL H. CLARKE, who was recently appointed lieutenant-governor of the province of Ontario, has withdrawn his resignation as chairman of the Toronto Harbor Commission and has agreed to continue in that office at the request of the other members of the commission.

ROBERT FLEMING, civil engineer, of Aberdeen, Scotland, has joined the financial firm of J. & L. M. Wood, which will hereafter be known as Wood, Fleming & Co. Mr. Fleming served with the Canadian forces overseas. For several years prior to the war he was a railway contractor in this country.

STUART S. SCOVIL, of the Dominion Water Power Branch, Ottawa, has been appointed engineer in charge of the hydrometric surveys in the province of Ontario, and JAMES R. BISSETT, of the same branch, has been appointed assistant engineer. This work in Ontario has formerly been taken care of by the Hydro-Electric Power Commission, but by arrangement with that commission it will be done in the future by the Dominion Water Power Branch, whose records will be used by the commission.

A. H. HARKNESS and R. E. W. HAGARTY, Toronto, have been appointed joint consulting engineers for the proposed

18-story addition to the King Edward Hotel, Toronto. Watt & Blackwell, of Toronto, Ont., have been retained as associate architects to prepare the plans for the United Hotel Co.'s architects, Essenwein & Johnson, of Buffalo, N.Y.

Lt.-Col. Dougall Carmichael, minister without portfolio in the recently elected Ontario cabinet, has been appointed by the provincial government as its representative upon the Hydro-Electric Power Commission of Ontario. Hon. I. B. Lucas retains his seat on the commission for the time being at least, so that at present all three positions on the commission are filled, Sir Adam Beck remaining as chairman.

Charles Sumner Lund Hertzberg, who was recently relieved of his military duties after having been in the army since December, 1915, has returned to private practice in Toronto and, in partnership with Thomas R. Loudon, has formed a new firm, Loudon & Hertzberg, consulting industrial and structural engineers. Mr. Hertzberg was born June 12th, 1886, in Toronto, and was educated at the Toronto public schools, St. Andrew's College (Toronto) and the School of Practical Science, University of Toronto, from which he graduated in 1905, taking a post-graduate course in 1905-6. Having spent his summer vacations on C.P.R. location work, he joined the staff of that railway in the fall of 1906 as a transitman on maintenance. He was employed in 1907 by the Trussed Concrete Steel Co., in their Toronto office, as a draftsman and designer. In the latter part of 1907 he joined the construction staff of the Concrete Engineering Construction Co., but returned to his previous position with the Trussed Concrete Steel Co. early in 1908. A few months spent on electric railroad maintenance with the Dominion Power & Transmission Co., Hamilton, Ont., intervened prior to his appointment, in the spring of 1909, as chief engineer of the Trussed Concrete Steel Co. at that company's office in Walkerville, Ont. In 1911 Mr. Hertzberg joined the Bishop Construction Co. as Toronto manager, and in the following year became a member of the firm of James, Loudon & Hertzberg, consulting engineers, Toronto, and was engaged in structural and municipal undertakings until he joined the Engineering Training Depot at Ottawa in December, 1915. On New Year's Day, 1916, he sailed for England as lieutenant in charge of a reinforcement draft, and in England he was assigned to the 7th Field Company, Canadian Engineers. That company crossed to France in April, 1916, and Mr. Hertzberg continued with them until he was wounded in January, 1917. In Corps Orders of December 5th, 1916, he was gazetted to receive the Military Cross for his work on the Somme. Invalided to Canada in July, 1917, he became adjutant at the Spadina Ave. Hospital, Toronto, and was promoted to captain and officer commanding casualty company. He was transferred to No. 2 Service Company in July, 1918, and in September, 1918, he joined No. 16 Field Company, Canadian Engineers, at Brockville, Ont., as second in command. Mr. Hertzberg went to Siberia with No. 16 Field Company, sailing from Vancouver October 11th, 1918, and at Vladivostok he was attached to the force commanded by Major-General Elmsley. Mr. Hertzberg's company was the only engineering unit with the force, and it was employed on water supplies, the construction and repair of barracks, the repair of roads, and other work. In April, 1919, Mr. Hertzberg was placed in command of the company, with the rank of major. Two months later he returned to Canada with the headquarters staff of the expeditionary force.

J. Duchastel de Montrouge, who was recently nominated for a vice-presidency of the American Road Builders' Association, has been notified that he has been elected vice-president of the Northeastern District of that association. Mr. Duchastel is a past president and director of the Canadian Good Roads Association.

William Gore, of Gore, Nasmith & Storrie, consulting engineers, Toronto, has sailed for England on a business trip, which is to include an investigation of the latest developments in the treatment of trade wastes and sewage disposal.

J. E. Milne, municipal engineer of Burnaby, B.C., has been selected by the Saanich municipal council, Vancouver Island, as municipal engineer for that district. Mr. Milne was in the Canadian army during the war, and since his return from overseas has been with the Burnaby municipality.

Robert Verity, of Toronto, a well-known labor contractor who has supplied upwards of 100,000 men to contractors and manufacturers in Ontario during the past sixteen years, will said for England next week in order to investigate the prospects for increasing immigration during the coming year. Mr. Verity expects to return to Canada in February.

William R. Worthington, engineer of sewers, Works Department, city of Toronto, has resigned and will enter private practice in Toronto. Mr. Worthington is a civil engineering graduate of the University of Toronto, class of 1905. During his summer vacations, while at the university, he was connected with the Roadway Department of the city of Toronto, and after graduation he was appointed assistant sewer engineer. In 1912 he was appointed engineer in charge of the sewer section. During his tenure of office the sewer section has carried out work costing nearly $8,000,000 and has made several reports on proposed schemes, including sewage disposal for the entire city and sewerage scheme for North Toronto. Besides the amount above mentioned, Mr. Worthington also supervised the expenditure of large sums annually for the maintenance of the entire sewerage system of the city. During the absence of F. A. Dallyn, provincial sanitary engineer, who went to Siberia last fall with the Canadian expeditionary force, Mr. Worthington acted as consulting engineer to the Ontario Board of Health.

OBITUARY

Stephen Pearson Brown, formerly chief engineer of the Mount Royal Tunnel & Terminal Co., Ltd., Montreal, was drowned last Sunday in Sebec Lake, Maine. Mr. Brown was pulling his nine-year-old son on a sled when the ice broke under him and he sank before the boy could summon help. Mr. Brown was about forty years of age. He was a graduate of the Massachusetts Institute of Technology, and before going to Montreal had been associated with the construction of the Pennsylvania Tunnel in New York City. He went to Montreal in 1912 in charge of the Mount Royal Tunnel project and superintended the design and construction until the work slackened in 1916, when he returned to the United States as vice-president and manager of Ford, Bacon & Davis, a well-known firm of engineering contractors of New York City. Mr. Brown continued to act in a consulting capacity in regard to the Montreal terminal work for the C.N.R., and was expected in that city this month on business in connection with the C.N.R. enterprise. From 1915 to 1917 he was a member of the council of the Canadian Society of Civil Engineers. Mr. Brown was also a member of the Institution of Civil Engineers of Great Britain, the American Society of Civil Engineers and numerous other engineering, railway and scientific societies.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Batiscan, Que.—The MacKinnon Steel Co., Ltd., of Sherbrooke, Que., has been awarded the contract for the steel superstructure of the highway bridge which the Quebec provincial government has arranged to erect over the Batiscan River on the Montreal-Quebec Highway. This bridge, which is over 1,200 feet long, will be one of the largest highway bridges in the province of Quebec.

Belleville, Ont.—City council intends to construct asphaltic concrete pavements on Ann, Charles, William and John Sts. at a total estimated cost of $92,461.20. City clerk, J. Wilfred Holmes.

Belleville, Ont.—City council will construct an asphaltic concrete pavement on Bridge and Pinnacle Sts.

Brockville, Ont.—Leeds and Grenville county councils passed a by-law designating several roads as county roads for improvement under the Highways Improvement Act.

Galt, Ont.—City council intends to construct a cement concrete sidewalk on Hobson St.

Guelph, Ont.—The city council and Wellington County Council are considering the erection of a new bridge on Victoria Road. City engineer, F. McArthur.

Halifax, N.S.—Tenders addressed to the Provincial Highways Board, Halifax, N.S., and endorsed on the envelope, "Tenders for Annapolis and Allen Creek Bridges," will be received up to noon of January 5th, 1920. Plans and specifications may be obtained upon application to the office of the Provincial Highways Board, Halifax, N.S.

Hamilton, Ont.—Works Department plans grading of parts of Connaught Ave., Beechwood Ave., Cannon St. and Balsam Ave.; cement sidewalks on Homewood Ave. and King St.; cement curb on Tisdale St., and grading work on McKittrick Boulevard, King and Dundas Sts.

Hastings County, Ont.—A Mud Creek bridge between Wollaston township, in this county, and Chambers township, Peterboro' county, is to be rebuilt. County road superintendent, H. G. Bleecker, Frankford, Ont.

Megantic County, Que.—County council plans construction of gravel road. Secretary-treasurer, L. Houde, Plessisville, Que.

Niagara Falls, Ont.—American Can Co. plans erection of bridge. Manager, E. R. Coulson.

Ottawa, Ont.—City council will petition the Quebec government to take over and maintain as a government highway the road from Eddyville to Aylmer.

Port Credit, Ont.—Plans have been prepared by the Toronto-Hamilton Highway Commission, 49 Wellington St. East, Toronto, for a small bridge near here.

Specification may be obtained at the office of the City Light and Power Department, 54 King St.

Barrett Specification Roofs

20 Years of Service Guaranteed—

IN the old days buying a roof very often proved to be something of a gamble. Maybe you got just what you specified, and maybe not.

The cost per square foot was too often taken as the only standard of value—frequently to the owner's subsequent sorrow.

Today all this is changed.

It was The Barrett Specification which first made it possible for building owners everywhere to obtain, through their local contractors, a *standardized roof*, worked out by roofing engineers and based on scientific principles of modern roof construction.

Today we offer to *guarantee* Barrett Specification Roofs *for a period of 20 years!*

This guaranty is obtainable on any roof of 50 squares or more, in any town of 25,000 population or over, and in smaller places where our Inspection Service is available.

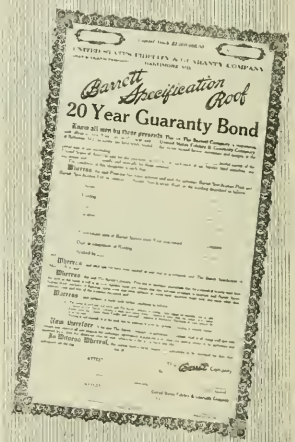
It is a Surety Bond, issued by a well-known Fidelity and Guaranty Company.

To obtain this Surety Bond you have only to insert in your building specifications the following:

> "The roof shall be laid according to The Barrett Specification dated May 1, 1916, and the roofing contractor shall secure for me (or us) the 20-Year Guaranty Bond therein mentioned."

The guaranty costs you nothing. We merely require that the roofing contractor be approved by us and that we be given an opportunity to inspect the construction.

We shall be glad to send you a copy of *The Barrett Specification*, with diagrams, ready for insertion in your building plans.



Barrett Specification Roof
20 Year Guaranty Bond

The 20-Year Bond

We illustrate above the 20-Year Surety Bond that will be given on all roofs of 50 squares or over in towns of 25,000 population or more and in other places where our Inspection Service is available.

Moncton, N.B.—Geo. A. Fuller Co., 285 Be[illegible]l Hill, Montreal, have general contract for concrete [illegible] for T. Eaton Co., Toronto. Electrical work will be le

Burlington Steel Co., Ltd.
Hamilton, Canada

STEEL BARS
For
Concrete Reinforcing

THE MOST IMPORTANT FACTOR IN CONCRETE REINFORCEMENT IS THE TENSILE STRENGTH AND ELASTIC LIMIT OF THE REINFORCING BAR.

OTHER THINGS BEING EQUAL, STEEL HAVING THE HIGHEST ELASTIC LIMIT, OR YIELD POINT, WILL BE THE MOST SATISFACTORY FOR REINFORCEMENT. WHEN UNDER STRAIN, AS SOON AS THE ELASTIC LIMIT OF ANY REINFORCING BAR IS REACHED, THE METAL STRETCHES RAPIDLY DECREASING IN SECTION, DRAWING LOOSE FROM THE CONCRETE AND DESTROYING THE MONOLITHIC BOND EXISTING BEFORE THIS POINT IS REACHED THEREFORE, THE SAFETY OF THE ENTIRE CONSTRUCTION IS IN DIRECT PROPORTION TO THE ELASTIC LIMIT OF THE STEEL USED.

THE ELASTIC LIMIT OF RAIL CARBON STEEL IS 50,000 TO 60,000 POUNDS PER SQUARE INCH, EITHER TWISTED OR PLAIN, AS COMPARED WITH AN ELASTIC LIMIT OF 25,000 TO 30,000 POUNDS IN SOFT STEEL.

THAT'S WHY RAIL CARBON STEEL, WITH ITS 80,000 POUNDS MINIMUM TENSILE STRENGTH, IS RECOMMENDED AS BEING FAR SUPERIOR FOR ALL KINDS OF REINFORCED CONCRETE WORK.

AT OUR HAMILTON, ONT., WORKS WE BUY SELECT RAILS, AND ROLL THEM INTO RAIL CARBON STEEL REINFORCING BARS IN A PLANT WHICH IS THE EMBODIMENT OF THE LATEST THOUGHT AND PRACTICE.

THESE BARS CAN BE SUPPLIED FROM STOCK IN VARIOUS SIZES, LENGTHS AND SHAPES. WE CAN ALSO ROLL SPECIAL SHAPES AND SIZES TO FIT YOUR PARTICULAR REQUIREMENTS.

Bars bent to shape for Beams, Stirrups, Etc.

PROMPT SHIPMENT

Moncton, N.B.—C. W. Dobson, 1502 Main St., is building skating rink costing $50,000 to $60,000. Architect, John Ryan, Chatham, N.B. Electrical work will be let.

Montreal, Que.—Canadian Buttons, Ltd., 722 Visitation St., plan erection of factory to cost $50,000. Secretary, A. B. Stein.

Montreal, Que.—Montreal Warehousing Co., 234 Wellington St., will probably rebuild their warehouse, recently destroyed by fire with loss of $30,000.

Branch Offices:— Toronto Winnipeg Regina Calgary Vancouver

Toronto, Ont.—The Works Committee of city council approved plans for the erection of a new Loew's Theatre on Yonge St., near Bloor. Another theatre plan passed was one for the Eastern Theatres, Ltd., for an amusement house on Victoria St.

Toronto, Ont.—Following building permits have been issued by City Architect's department: Toronto Housing Commission, 17 pairs semi-detached two-story brick and stucco dwellings, Annette St., corner of Spears, $104,000; Irvine Lumber Co., one-story open lumber shed, also addition to warehouse, 26 Vine St., $1,300; Harris Abattoir, automobile shed, west side of Symes Rd., near St. Clair, $3,000; Canadian Fairbanks-Morse Co., grinding and cleaning-room, 1383 Bloor St. West, $24,000.

Toronto, Ont.—Separate tenders addressed to T. L. Church (Mayor), chairman of the Board of Control, for the work included in the specifications of the several trades mentioned below in connection with the erection and completion of public lavatories will be received up to noon on Tuesday December 16th, 1919: (1) Mason work, (2) carpenter work, (3) metal work, (4) plumbing, (5) hot-water heating, (6) electric wiring and fixtures, (7) plastering, (8) painting and glazing. Plans and specifications may be seen at the office of the City Architect, city hall, Toronto.

Toronto, Ont.—The City Architect's department estimates that the city will enjoy a big building boom in 1920 to the extent of quite $24,000,000 worth of permits. The nearest approach to this figure was secured in 1912, when $27,000,000 was passed upon. Baldwins, Ltd., have filed plans for a $200,000 steel plate mill at Ashbridge's Bay. This is the first of a series of buildings for the firm. The total expenditure will be about $1,500,000. Dunlops, Ltd., are building a new factory at Queen and Booth Ave. to cost $450,000.

Vancouver, B.C.—Permit issued for erection of a new tire service station at 1301-1303 Granville St. for the Howard and Davis Tire Co. at cost of $10,000. Contract let to B. Davidson.

Vancouver, B.C.—Permit issued to Jules and Jay J. Allen, Toronto, for erection of new Allen Theatre, estimated to cost $300,000. Chief architect, C. Howard Crane, of Chicago, who has associated with him E. G. Kiehler. General contract has been let to Alex. McDonald, of Winnipeg, who has let a sub-contract for the excavation to A. B. Campbell, Vancouver.

Victoria, B.C.—Tenders are being called for by the Canadian National Ry. for the erection at the Songhees Reserve terminals of a five-stall engine-house and machine shop.

Walkerton, Ont.—Hanover Portland Cement Co., Hanover, Ont., plan to build quarry costing $200,000.

Walkerville, Ont.—Plans are under way for a memorial hall and clubhouse for the Ford and Walkerville branch of the Great War Veterans' Association.

Welland, Ont.—Brazil Motors Co., Brazil, Ind., plan erection of factory.

Welland, Ont.—Plans will be prepared for city council for erection of a combined market building and band hall.

Westboro, Ont.—The Westboro and District Branch of the G.W.V.A. plan erection of hall.

Weston, Ont.—Weston branch, G.W.V.A., plan erection of clubhouse. President, R. H. McInnes.

Weyburn, Sask.—Saskatchewan Co-operative Creameries, Regina, plan erection of creamery and cold storage plant to cost $100,000. President, C. Paynter, Tantallon.

Wingham, Ont.—Contract for the woodwork let to W. H. Rintoul and for the brickwork to Mr. Brown in connection with erection of new Wingham Fair building. Estimated cost, $5,000.

Winnipeg, Man.—Construction will commence early in the spring on the first lignite manufacturing plant in western Canada, J. M. Leamy, Provincial Power Commissioner for Maintoba, announced last week. The plant will be located six miles south-east of Bienfait, Man., on a spur of the C.P.R. All the buildings will be of steel.

MISCELLANEOUS

Barton Tp., Ont.—By-law to provide $8,500 for purchase of a stone-crushing machine will be submitted to ratepayers at January elections.

Ottawa, Ont.—Contract let to W. G. Edge, Ltd., Ottawa, for $24,984 for supply of kitchen equipment for Parliament Buildings.

Ottawa, Ont.—The following are among the companies recently incorporated: The Oakoal Co. of Canada, Ltd., Toronto, capital $1,250,000; Gear Produce of Canada, Ltd., St. Catharines, Ont., capital $250,000; Western Wheel and Foundries, Ltd., St. Boniface, Man., capital $2,000,000; Canadian MacArthur Concrete Pile Co., Ltd., Montreal, capital $24,000; Charles E. Goad Engineering Co., Ltd., Toronto, capital $300,000; MacPherson Wire Co., Ltd., Hamilton, capital $400,000; Canadian Inspection and Testing Co., Ltd., Toronto, capital $40,000.

Petit Rocher, N.B.—Dominion Department Public Works let contract to Thos. P. Charlton, 179 Gilmour St., Ottawa, for repairs to breakwater.

Port Arthur, Ont.—The Federal Mining Co. has been incorporated with a capitalization of $40,000, the officers being F. S. Wiley, G. C. Gibbs and W. D. B. Turville.

Regina, Sask.—W. F. L. Edwards proposes to erect a dance pavilion at Wascana Lake at a cost of $20,000.

Sarnia, Ont.—Lambton county council is considering the purchase of stone-crushers.

Smith's Falls, Ont.—Town council decided to submit two by-laws to the people at the elections in January, one to grant certain concessions to the Canadian Cooperage Co., which intends to establish a new plant here, and the other to raise $25,000 for the erection of a new fire hall and the purchase of a chemical motor engine and hose truck and other equipment.

Ste. Famille, Que.—Contract let by Dominion Department Public Works to O. Poliquin, Portneuf, Que., for repairs to wharf.

St. John, N.B.—Mayor Hayes announced that he had been assured that the new drydock in Courtenay Bay, which will be the largest in the world, will be completed in two and a half years.

St. John, N.B.—A deputation composed of Senator W. H. Thorne, Brig.-Gen. H. H. McLean, M.P., and R. W. Wigmore, M.P., have gone to Ottawa to urge the government to proceed with improvements already planned for the port of St. John. The work the deputation wishes to see undertaken is quite apart from the Courtenay Bay development scheme. The delegation will also urge the government to proceed with the plan to make St. John a national port under the control of a harbor commission.

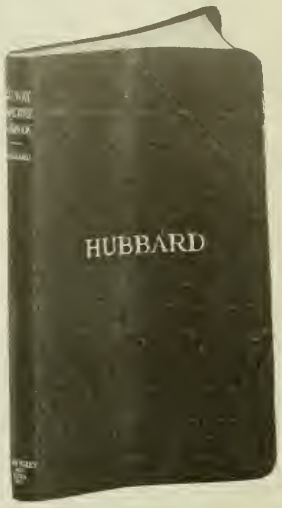
Sydney, N.S.—An expenditure of over half a million dollars is to be made by the Dominion government at Sydney in the preliminary work in connection with the construction of the new terminal facilities for this port. Mr. Gregory, an official of the survey staff at Ottawa, is at present in the city taking some necessary soundings near the old government wharf and running some levels in the vicinity of Victoria Park. The department at Ottawa have practically all the necessary data on hand for the construction of the terminals and it is expected that tenders will be called for shortly for the work to be done. The government has already set aside in the estimates $100,000 for the erection of a new wharf. The construction of railway facilities will involve an additional expenditure of four or five hundred thousand dollars.

Toronto, Ont.—The following companies have been incorporated: Machinery Supplies, Ltd., head office at Toronto, caiptal $40,000; Hudson-Porcupine Gold Mines, Ltd., head office at Toronto, capital $1,500,000.

Vancouver, B.C.—A number of recommendations for the improvement of Vancouver harbor were made by the Vancouver Board of Harbor Commissioners at an interview with Hon. C. C. Ballantyne, Minister of Marine, Ottawa.

A Brand New Highway Inspectors' Book

Highway Inspectors' Handbook



By PRÉVOST HUBBARD, Chemical Engineer; formerly Chief, Division of Road Material Tests and Research, Bureau of Public Roads, U.S. Department of Agriculture.

This book presents as briefly as possible and in such form as to be quickly available to the inspector, most of the important details of highway construction and maintenance. Diagrams are used in place of tables, giving data in convenient form for field use. The most reliable data obtainable have been employed, both from the author's own experience and from various records of work done throughout the country.

Inspectors, engineers and contractors will find this book an invaluable assistant in their every day work.

xxvi+372 pages. 4¼ by 7. 55 figures. Flexible "Fabrikoid" binding, $2.50 net.

BY THE SAME AUTHOR

Dust Preventives and Road Binders

By PRÉVOST HUBBARD.

Furnishes road engineers with a working knowledge of the characteristic properties of dust preventives, and develops fundamental principles relative to their selection and use.

vii+416 pages. 6 by 9. 51 figures. Cloth, $4.00 net.

Laboratory Manual of Bituminous Materials

By PRÉVOST HUBBARD.

Describes methods in sufficient detail to enable the student to make the more common and widely used tests with reasonable accuracy.

They include the construction of a modern 1,300-foot wharf on Burrard Inlet, the institution of a car-ferry service to connect North Vancouver with Vancouver, and the construction of a terminal railway system. The improvements will probably cost several millions. It is understood that the Minister of Marine regards the proposals of the commissioners favorably.

Vancouver, B.C.—Tenders are being called up to December 29th by the C.P.R. for the dredging and filling work for the new "B" and "C" piers which the company is going to build in Burrard Inlet. It is expected that this work will take from seven to ten months to complete, and will cost about $500,000. The exact style of the new dock has not yet been decided upon, but the total cost will run into several millions of dollars.

Victoria, B.C.—New companies recently incorporated include the following: The Temple Contracting Co., Ltd., $10,000, Vancouver; British American Smelting Co., Ltd., $1,000,000, Vancouver; Co-operative Building Co., Ltd., $100,000 Vancouver; Canadian Adjustable Double Dock Co., Ltd., $500,000, Vancouver.

Winnipeg, Man.—The Hudson Mines have been incorporated with a capitalization of $5,000,000. The promoters of the company are H. R. McTavish, J. C. Finn, N. McTavish and E. B. Baldwinson.

Tenders Called For

YORK TOWNSHIP

Sealed tenders will be received by the Council of the York Township up to noon on Saturday, 17th January, 1920, for each of the following contracts:—

5,000 lengths 6-inch cast-iron pipes, more or less.
1,000 " 12-inch cast-iron pipes, more or less.
1,000 " 16-inch cast-iron pipes, more or less.
500 tons (about) 6-inch, 12-inch and 16-inch cast-iron specials.
200 6-inch gate valves, more or less.
30 12-inch gate valves, more or less.
20 16-inch gate valves, more or less.
250 hydrants, more or less.
250 round cast-iron valve covers and frames, more or less.

Specifications, forms of tender and further information may be obtained on application to the undersigned.

The lowest or any tender will not necessarily be accepted. The Council may divide the contracts as they may deem expedient.

All envelopes must be plainly marked on outside what tenders they contain, and they must be addressed to—

FRANK BARBER,
Township Engineer,
40 Jarvis St., Toronto.

A Weekly Paper for Civil Engineers and Contractors

Proposed Development of Hamilton Harbor

Report Presented This Week to Hamilton Harbor Commission, Recommending Creation of 1,250 Acres of Park and Residential Property, 1,198 Acres of Industrial Land, 6.26 Miles of Docks and 16.98 Miles of Boulevard

By JOHN M. WILSON
District Engineer, Public Works Department of Canada

HAMILTON harbor, situated at the westerly end of Lake Ontario, possesses natural advantages that are not surpassed by any other harbor on the Great Lakes. Its present area at normal Lake Ontario level (elevation 246 above mean sea level, New York), is 6,973 acres, varying in depth from shallow water in the marshes to 80 ft. in the harbor proper. Of this total area, 4,500 acres has an existing governing depth of 18 ft., or sufficient to take care of present Welland canal draught. The harbor is land-locked with the exception of a channel (maintained by the Dominion government) at the entrance to Lake Ontario, and has a normal shore line of 32.78 miles.

A casual reference to the plan showing the existing conditions (see page 538), and consideration of same in reference to the size of the city of Hamilton, conveys the impression that complete development of Hamilton harbor involves a cost disproportionate to the size and needs of the community affected. This was taken into consideration during the early stages of the investigation into the possibilities of Hamilton harbor, and it was thought wise to make the proposals as complete as possible, looking to the future growth of the city. The work projected on the plan on page 539 may not be completed for a number of years, but if the scheme as a whole be adopted, the foundation will have been laid for continuity in planning construction operations to be undertaken from year to year as finances will permit.

In the year 1873 the population of Hamilton was 30,000; the (municipal) census of 1919 gives a population of 110,000. Using the rate of growth shown by these figures, a curve might be projected into the future in order to determine the probable population at any given time, but I do not believe that any such estimate would be conclusive. Hamilton's location as a logical manufacturing and distributing centre should attract a large percentage of the immigration that I am reliably informed will shortly come to this country from the British Isles, and this, together with the natural development of Canada during the next few years, should greatly accelerate the city's growth.

Provides for 30-Ft. Draught

In planning for the future in works of this nature it is necessary to consider the requirements of a community many years in advance, and to take into account what the possibilities of an inland port situated as is Hamilton, will be when the St. Lawrence and Welland canals are deepened and ocean tonnage is brought to the Hamilton docks. I may say that a very strongly organized movement is now under way to bring about the deepening of the St. Lawrence canals, and Hamilton would particularly benefit on account of the very large export tonnage that would be handled over the harbor.

An essential to the successful development of a harbor, from an industrial and commercial standpoint, is public control of the waterfront properties. In this regard the Hamilton Harbor Commission is not in the position it should be. A large portion of the waterfront property is privately owned or controlled, and in order to put the commission in possession of assets that would form a sound basis for negotiation with private interests, and furnish lands for industrial development, it was deemed expedient to recommend the establishment of a new harbor headline in accordance with the limits of the work outlined on the development plan.

The scheme in general provides for ships drawing 30 ft. of water, or ultimate Welland canal draught, to dock in slips at the city of Hamilton and alongside wharves constructed in what is at present the waters of the harbor, and serving lands created by reclamation with material dredged and pumped from the bed of the harbor; the serving of these industrial lands with steam and electric transportation, concentrated on what is termed a marginal way; and the creation of new park lands and recreation centres, coupled up with a boulevard drive 16.98 miles long, encircling the entire waterfront.

Nineteen Tentative Plans Studied

A complete survey of the harbor and vicinity has been made, soundings taken over the dredging and reclamation areas, and borings made to ascertain the nature of the material to be moved, and nineteen tentative study plans were prepared before the layout suggested herein was adopted.

The decision to concentrate to a large extent the industrial development to the east of James street was made after a careful study of existing conditions, embodying the natural advantages of the land in that section of the harbor, its accessibility to service, its adaptability to reclamation, and its relative ease of acquirement.

This industrial development is divided into two main districts: (1) The one lying south of Burlington street, between Wellington and Wentworth streets; and (2) the one lying within Gage avenue, Burlington street and Beach road.

This leaves the waterfront development of the property between Wentworth street and Gage avenue (where large industrial plants are now located), a matter for future consideration and negotiation. The latter property lends itself to incorporation in the general scheme, as shown dotted on the waterfront development plan, but its failure to be brought into the general scheme does not deprive the other districts of adequate transportation facilities, it being possible to render service from existing lines. There is also the possibility of extension to the west of Wellington street as far as the Desjardins canal, but it is not anticipated that anything in the nature of permanent works would be required beyond James street for many years, although it would seem desirable for the commission to acquire control of the property.

The area that it is proposed to develop industrially is shown in solid outline, hatched, on the waterfront development plan on page 539, and more particularly detailed on the sketch on pages 546 and 547, showing cross section at foot of

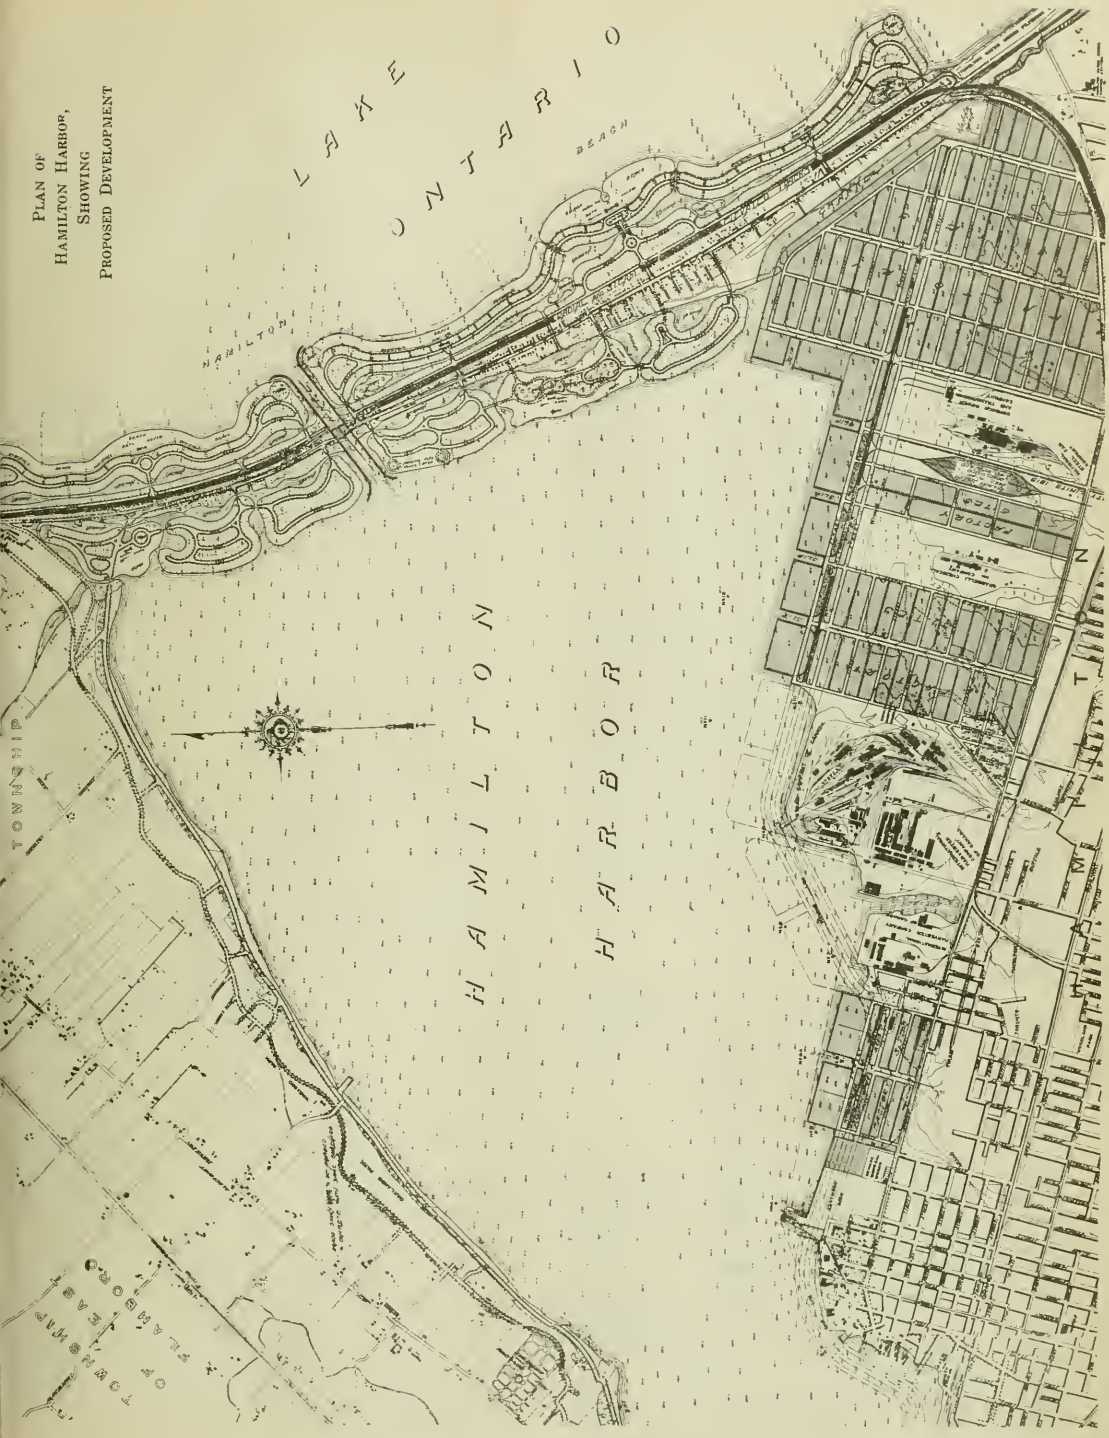
PROPOSED DEVELOPMENT



Wellington street. It comprises 6.26 miles of docks, having slips 600 ft. long and 200 ft. wide, enclosing an area of 1,198 acres. Of this total acreage, 311 acres are taken up with streets, trackage right-of-way, sorting and distributing yards for freight, etc., leaving a net area of 887 acres of leasing and revenue-producing property. This area and length of dock wall would be subject to variation depending on the number and location of slips that it might be desirable to construct in order to provide the required accommodation for prospective industries.

The areas lying to the north of the marginal way are for the accommodation of plants requiring rail and dockage facilities immediately adjacent to their buildings, while the

(Continued on page 545)

$2,357,000 SEWERAGE SCHEME RECOMMENDED FOR EASTERN PART OF YORK TOWNSHIP, ONT.

YORK township, Ontario, is a district extending along the northern frontier of the city of Toronto from Scarboro on the east to the Humber river on the west, a distance of about fifteen miles. Its populated area varies from a depth of half a mile to three miles from the city limits of Toronto. The township council have desired for some time past to provide sewers for the more thickly settled parts of the district, and isolated schemes had been prepared, but when application was made to the city of Toronto for outfall facilities, the city authorities pointed out that it would be desirable to have a comphehensive scheme prepared so as to enable both the township and the city to know where all the main outlets would be located.

When the matter came before the Ontario Railways and Municipal Board, it was firally agreed that the township council would authorize the preparation of a comprehensive scheme of sewerage.

Frank Barber, as township engineer, and R. O. Wynne-Roberts, who is associated with him, were instructed to make the necessary investigations and to prepare a preliminary scheme. These engineers have now presented their report and preliminary plans covering their recommendations regarding the eastern division of York township, and other reports and plans will be submitted in the near future, dealing with the western division and with the district known as Runnymede and Swansea. It will require several years to carry out these schemes in their entirety, but they are so designed that the township council may authorize the construction of any section at any time, and when the system is completed all the sections will fit into the general system and be economical of operation.

The eastern division is bounded on the east by the Scarboro township limits, on the west by the Don river, on the south by the city of Toronto and on the north by Don Mills road, Glebe road and the Canadian National Railway tracks. The division is subdivided into two acres, east and west of Woodbine heights, called Woodbine and Todmorden, respectively, the former having an area of some 400 acres, and the latter about 1,000 acres.

Different sites for sewage disposal works have been considered in their relations to the most economical schemes, and three main sites are reported upon, namely: (1) The brickyard site, located on land adjoining the Don Valley Brick Works; (2) the St. Clair site, on Don Mills road, north of the C.N.R. line; and (3) a site in the Woodbine district.

The report, dealing in outline with three possible schemes, defined as Scheme C, Scheme E, and Scheme CE, is in part as follows:—

Scheme C

Scheme C provides for a combined system of sewers for the entire eastern division, with the outfall works at the St. Clair site. The trunk sewers in this scheme would, in Woodbine district, be along Rosevear, Barrington, Valley, Lumsden, Cedarvale, Bracebridge, Woodbine and the street north of Plains road to Leslie; and in the Todmorden district, along Sammon, Cronyn, Davies Estate, Mortimer, McCash, Cosburn and the corresponding streets west of Leslie street. The main trunk would be along Leslie street to the St. Clair site.

This scheme would cost approximately as follows:—

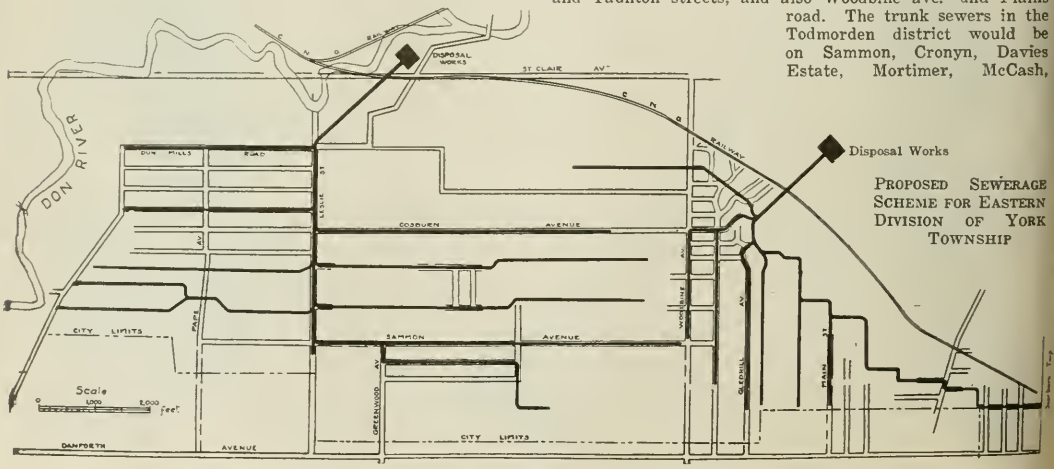
Woodbine—		
Trunks	$ 462,000	
Laterals	311,000	
		$ 773,000
Todmorden—		
Trunks	$1,176,000	
Laterals	488,000	
		$1,664,000
Disposal works		400,000
Total		$2,837,000

In this scheme the sewers are large enough to convey the entire flood water and sewage without relief. If relief sewers were provided, the cost of which would be deferred for many years, then the above total might be reduced by, say, $300,000.

Scheme E

Scheme E comprises two disposal works, one at Woodbine site and the other at the brickyard site.

The trunk sewers in the Woodbine district would be along Rosevear, Barrington, Lumsden, Westlake, Gresham and Taunton streets, and also Woodbine ave. and Plains road. The trunk sewers in the Todmorden district would be on Sammon, Cronyn, Davies Estate, Mortimer, McCash,



PROPOSED SEWERAGE SCHEME FOR EASTERN DIVISION OF YORK TOWNSHIP

Gower, Cosburn and Gamble, Plains road and Don Mills road.

This scheme would cost approximately as follows:—

Woodbine—		
Trunks	$ 289,000	
Laterals	264,000	
Disposal works	140,000	
		$ 693,000
Todmorden—		
Trunks	$ 991,000	
Laterals	40,000	
	380,000	
Disposal works	300,000	
		1,711,000
Total		$2,404,000

The above costs do not include relief sewers, which will parallel the trunk sewers and can be built when the streets are about to be paved and when the existing trunk sewers are working to their full capacities. It is not anticipated that relief sewers will be necessary for many years after the original ones have been constructed.

Scheme CE

Scheme CE would provide a sewerage system with two outfall works, one at the Woodbine site, and the other at the St. Clair site. The trunk sewers in the Woodbine district would be the same as already described in Scheme E, and the trunk sewers in the Todmorden district will be the same as described in Scheme C.

The cost of this scheme is estimated as follows:—

Woodbine—		
Trunks	$ 289,000	
Laterals	264,000	
Disposal works	140,000	
		$ 693,000
Todmorden—		
Trunks	$1,176,000	
Less relief sewers	142,000	
		1,034,000
Laterals	488,000	
Less relief sewers	158,000	
		330,000
Disposal works		300,000
Total		$2,357,000

In Scheme CE, the present savings which would be effected by providing future relief sewers are deducted so as to make a fair comparison with Scheme E, and it will be observed that these two schemes will cost about the same amount.

If the area south of Sammon avenue, be drained to the city, as the engineers think it should, then it will be possible to effect a tangible reduction in the cost of the remainder of the entire schemes. In view of the fact that the proposed schemes will dispose of sewage and storm water, and will thus relieve the city of the future disposal of storm water from the major part of the eastern division, it is recommended that the city be asked to deal with both sewage and storm water from the area south of Sammon and Cronyn avenues. It is also recommended that the subdivision of Davies Estate, adjoining Don Mills road and Cambridge avenue, be drained into the city sewers, for the reason that such method would be cheaper than connecting to the township sewers. The outlets can be arranged to suit city arrangement of sewers.

The engineers point out that in Scheme E, practically the whole of the sections west of Leslie street can be sewered without building the trunk sewer, but the latter must be constructed before the sewers in this section are fully developed, or the sections east of Leslie street can be undertaken.

In Scheme CE, the Leslie street trunk sewer must be built first, because it would be the only outlet for the sewage and storm water. Attention is also drawn to the fact that the construction of any portion of the system may be undertaken provided the works commence at the outfall ends.

Approximate annual capital costs of the two schemes, E and CE, have been computed on the basis of repayment, in the case of trunk sewers and disposal works, at 6% in 30 years, and in the case of laterals under 27 ins. diameter at 6% in 10 years.

In Scheme E, the total fixed charges amount to $215,600 per annum, or, on a frontage basis, an annual average cost of 55 cents per foot. In Scheme CE, the fixed charges total $207,097, or an annual average cost of 52.8 cents per foot. A tangible saving is shown when the figures are based on 30-year debentures at 6% for all works. Scheme E then totals $174,330, or 44.5 cents per foot; and Scheme CE. $171,075, or 43.6 cents per foot.

For puposes of comparison, it is interesting to note that the annual cost of different sewers excluding trunk sewers, already constructed in the township, ranged from 23.6 cents per foot seven years ago, to 53.31 cents per foot in 1917.

In making their recommendations as to which is the best scheme to adopt, Messrs. Barber and Wynne-Roberts state:—

"The problem of selecting the scheme which will be best adapted for future extensions, depends upon what new subdivisions will be placed on the market and what transportation facilities are available in the near future. For example, if the land along Independent road be subdivided, and a street railway is extended thereto, it would be necessary to anticipate the needs of that locality, and consequently the St. Clair site would be suitable. Furthermore, when the subdivision north of the Canadian National railway and east and west of Davies road, calls for sewers, then the Woodbine site will probably be suitable for most of it.

Scheme CE is Recommended

"For immediate development, the brickyard site offers some advantages. The Scheme E is more flexible, and it is the more natural outlet, and is accessible. It is, however, unfortunate that it is so near the residential portion, but for immediate purposes, it would be the one we would recommend. On the other hand, having regard to the future extensions of the populated areas, which of necessity must tend toward the north, we are prepared to recommend Scheme CE.

"If the brickyard site of Scheme E be carried out, it would be suitable for the future subdivision of the 80 acres west of Davies Estate homestead, and also for the parts lying off Todmorden road, but in the event of St. Clair site being adopted, it would be necessary to have a small independent plant for these areas."

Since 1912, $635,000 have been expended on London's sewer system. The city engineer's plans call for an additional $250,000 for 1920.

The eighteenth annual convention of the Canadian National Clay Products Association will be held at the Prince George Hotel, Toronto, January 20th to 22nd, 1920.

The engineer's report to the Vancouver and District Sewerage Board, presented recently, shows that the total expenditure since the inception of the board has been $2,253,915.

The Modern Housing Corporation, 435 Woodward Ave., Detroit, Mich., which is a subsidiary of the General Motors Corporation, is contemplating a housing scheme in Ontario and would be glad to receive catalogues from manufacturers of building materials.

Among the papers read before the Canadian Mining Institute recently in Vancouver, B.C., was one by William E. Greenwalt, of Denver, on the application of his process of electrolytic smelting of copper ores. Mr. Greenwalt predicted that in the near future electro-metallurgical methods will be so well established in connection with the copper industry as to compete successfully with the present system of smelters. The chief advantages of the process would be the elimination of the high cost of shipping ore from the mine to the smelter.

PATROL MAINTENANCE ON HARD SURFACE ROADS

By J. S. Crandell
Consulting Engineer, General Tarvia Dept., The Barrett Co.

SOONER or later all main line highways will be patrolled by repair gangs whose business it will be to maintain the roads under their care in satisfactory condition. Probably this would have been done long ago except for the fact that it seemed like a needless expense to pay wages to men to keep up roads that were thought not to need upkeep. But from the beginning the railways knew the value of section gangs, and the secret of low operating cost is largely perfect maintenance of track. Highway engineers have to learn the lesson; some of them have already learned it, and have profited thereby.

There is not much use trying to repair and keep in good shape a road built of poor materials on undrained soil. But given a good road, it is a simple matter to keep it in perfect condition all the year round if a system of intelligent maintenance is installed. Under these conditions, a well-built road will last indefinitely. A splendid example of what can be accomplished is found in Lucas County, Ohio. The county surveyor, Cecil L. Rood, has reduced the cost of maintenance from year to year, in spite of higher prices for labor and materials.

Fig. 1—Patrol House for Storing Road Materials

There are several points to be borne in mind in maintenance work:—

1. Train the men for the work to be done.
2. Keep on hand an adequate supply of materials for maintenance.
3. Use labor-saving devices.
4. Provide shelter where men can work in bad weather.
5. Keep materials, tools and other equipment locked up when not in use.
6. Keep accurate records of all work done, with cost, time, materials, etc., included.
7. Get out on the job often and "stick around."

One of the best investments in starting a patrol maintenance system is the acquisition of a building in which material and equipment may be stored, and where men can work. Such a building is illustrated in Fig. 1. Here a mixing board has been placed on which Tarvia KP and stone are being mixed as a patching material. (The mix should be stored away for a few days before using.) In this patrol house are kept shovels, screens, brooms, pick axes, wheelbarrows, sledge hammers, lockers for the men, etc. The house is well ventilated, and on a rainy day two gangs of mixers may be kept busy mixing and storing away the patching material for future use.

Often an old house or shed may be acquired for a patrol house. A little repairing or painting will make it suitable and attractive. Nor is it necessary to provide new and expensive equipment throughout. Fig. 2 shows how a barrel of Tarvia KP has been mounted on an old fire hose truck that had been discarded years ago. For $2 it was made into an excellent vehicle for moving barrels from the yard to the job. Similar economies will occur to the observant foreman or engineer.

Fig. 2—This Rig Cost Just Two Dollars

If the mileage to be covered by a patrol gang is extensive, it will be cheaper to buy a one or two-ton motor truck than to haul with horses. The wages saved by reducing time lost getting to and from the job will soon pay for the truck.

Many cities and counties are keeping their supply of bituminous patching materials in storage tanks. A convenient form for town or city plants is shown in Fig. 3. If the tank is to be used along country roads, it is better to place it with the long axis horizontal instead of vertical, and to elevate the tank sufficiently so that the cold patching material may flow by gravity into the wagons or trucks that the maintenance gang uses. Such a tank is inexpensive; about $150 for a tank holding 1,200 gallons is a fair price. The advantage far outweighs the initial cost.

Fig. 4 shows a convenient form of wagon for bringing the mix from the patrol house to the job. The one illustrated is a cart used formerly for collecting ashes and garbage. A bottom dump wagon is not so handy a type for this kind of work.

Fig. 3—Inexpensive Municipal Storage Tank

Much of the repair work has been done in the past with hot bituminous material. The cold patching products now on the market offer a great range of usefulness, and require less care and equipment. When a hot patch is to be made, the patrol gang must be provided with a suitable portable kettle for heating the tar, and with fuel sufficient for the day's work. "Cold patch" requires neither of these.

In using a tar cold patching material, several points should be observed:—

Don't use wet stone; don't use dirty stone; don't use too much tar (about 12 to 15 gals. of tar to the cubic yard of stone is about right); don't leave a freshly made patch of stone and tar uncovered in the rain (in wet weather it should be protected for a day); don't heat a tar cold patching material (if heat is necessary, warm the stone instead).

Mix one cubic yard of a mixture of one part coarse clean sand and three parts of ¾-in. stone, with 12 to 15 gals. of tar. Mix tar and stone first, then add sand. Let this mixture cure, or season, for a few days before using.

Clean out the hole to be patched; paint the sides of the hole with tar; deposit the mixture in the hole and tamp well; leave the patch slightly higher than the surrounding road metal (it will settle after a while); sand the top.

When the patch has set up hard, sweep it and give it a light seal coat of tar, and cover with sand or screenings. Do the painting with a brush. Do not pour a bucketful of tar on a patch; only a very light coat is required.

FIG. 4—PAINTING BOTTOM AND SIDES OF HOLE

Traffic will iron out the patch into a smooth surface. Some engineers prefer to use only tar and stone, with no sand. If the stone contains much fine material, the result will be satisfactory, but with a graded stone from ½-in. to 1¼-in., and no fines, the mix will be too open to make a good patch, and sand is necessary.

The value of training the patrol gang cannot be overestimated. Get them to do the work right from the start and much worry and trouble is eliminated.

And patch! Patch *every* hole, large or small. The earlier you can catch them, the less there is to do. Patch breaks in bituminous or cement-concrete surfaces as soon as they appear. Often a paint coat of tar with a coating of clean chips or gravel will prevent the formation of a hole.

Be sure to clean thoroughly the surface to be painted. Don't attempt to apply tar to a dusty, mud-caked pavement, for the tar will not stick, nor will it retain its characteristic properties. By using care and judgment, skin patches of considerable area and thickness may be built up. Use clean stone chips or ½-in. gravel for covering material instead of sand, because sand is likely to cause the material in the patch to wave or bunch; chips or gravel prevent this.

Follow up every complaint; determine the cause, and supply the remedy then and there.

Patrol maintenance means perfect roads every day of the year. It means lowered cost of maintenance. It also means putting off reconstruction indefinitely, and that means lower taxes.

TORONTO'S MARGINAL BOULEVARD

By Reginald B. Evans
Engineer of City Parks, Toronto, Ont.

FOR some years a survey has been under way for a marginal boulevard surrounding the city of Toronto. Plans and profiles have been plotted, costs of grading estimated, some work done along the south or lake-front side, and three miles of road built along the west margin of the city up the picturesque valley of the Humber river.

The latter section is much used by automobiles, as it connects the Hamilton highway with Dundas street and lies

A PICTURESQUE PART OF THE BOULEVARD

through more than one hundred acres of park land owned by the city. This part of the boulevard has grown from an early trail used by our forefathers to carry grain from Lake Ontario to the old mill at Bloor street on the Humber river.

The first pavement was laid some ten years ago of concrete and is still in good repair, although it has been widened from 16 ft. to 30 ft. The road from the lake to Bloor street for the most part follows the top of the ridge of land lying between the Humber river and the ravine to the east. Little or no drainage was required on this part; some heavy clay cuts were made, however, and for several years trouble was experienced in these from heaving with frost and flooding. Finally weeping tiles were put along the side of the road and no difficulty has arisen since.

Where the road descends into the valley, a 5½% grade is used for 1,300 ft. This hill is not paved with concrete but with tar macadam, as are all the steep hills. At Bloor street the boulevard crosses the Humber river on a hand-

HUMBER SECTION OF BOULEVARD DURING CONSTRUCTION

some stone bridge built jointly by the county of York and the city of Toronto. This point is about one and a half miles from the lake and is the head of navigation for small boats. During the summer and well on into October, canoes ply this river in great numbers and small boys bathe along its shores.

On the west bank of the river, space is provided for parking automobiles, and a commodious tearoom is open the year round. The road from there north follows the west bank of the river, and in places is cut out of the high bank, where springs of water and seepage had to be taken care of by drains and ditches. For a distance of several hundred feet, the only location for the roadway was through a swampy piece of land at the foot of a hill. To get a foundation it was found necessary to lay weeping tile along the west side of the road, next to the hill, and to fill over the swamp high enough to get the road up out of the wet. The drain pipe is about three feet below the surface, and runs both ways from the summit. The swamp probably has fairly well dried out since construction some five years ago, and no trouble has been experienced. From this point north as far as Dundas street, the road is finished but no planting has been done, the scenery along the river being the principal charm.

From Dundas street the survey follows the Humber river and Black creek to the point where this creek goes under the Grand Trunk railway's northern division. This valley is laid out in golf grounds, market gardens and

Boulevards are Profitable When They Bring This Nearer to Kiddies of Crowded Cities

farms. The side hills are well wooded and a road is needed to develop the growing suburb.

From the Grand Trunk the proposed boulevard follows an 86-ft. diagonal road in a northeasterly direction to the corner of Dufferin street and Lawrence avenue. This is part of the system of diagonal roads as laid out by the city surveyor, comprising a comprehensive scheme for the future of the city. This diagonal road system is followed for another mile and a half across level farm lands to where the boulevard route descends into the valley of the Don river. This section has been marked out by stone monuments for some five years, and all real estate plans are required to conform to it.

Following the Don river, the next mile brings the proposed road to Yonge street at York Mills, whence the drive can go down Yonge street for a mile to Hog's Hollow or follow the ravine a short distance west of Yonge. The west branch of the Don is followed through golf grounds and farm lands for about three miles to its junction with the main Don river. The scenery through this valley is beautiful, the road passing under the high Canadian Pacific Railway viaduct, where a special opening was made, during its recent reconstruction, at a cost to the city of about $6,000. This part of the drive could be easily constructed of gravel found along the route and later could be widened to accommodate future traffic.

From this point the route follows the valley of Silver creek to the eastern city limits, where it turns south to the Kingston road and thence via Woodbine avenue to the lake, joining the proposed Harbor Commissioners' road along the lake front to the Humber river.

The proposed marginal driveway is about forty miles in length, and approximately thirty miles are already secured to the city by present roads and promises of free rights-of-way 100 ft. wide through private property.

The alignment of the boulevard is made up of straight tangents and regular curves. The grade for the most part is light and conforms closely to the rise and fall of the ground.

The marginal boulevard is under the jurisdiction of Charles E. Chambers, commissioner of parks for the city of Toronto, while the southern, or lake-front link, referred to above as the Harbor Commissioners' road, will be constructed for the city by the Toronto Harbor Commission. A start was made this year on the first 8,000 ft. of the Harbor Commissioners' road, the construction being hot-mix asphaltic concrete on a cement-concrete base, 50 ft. wide.

THE TOWN PLAN AND THE FACTORY

By Louis Blake Duff
Welland, Ont.

ONE of the largest and best known industries in Ontario found it necessary a short time ago to provide for a considerable enlargement of its plant. One thinks of a plant enlargement as something added on to a building or set of buildings already existent. In this case, however, the new plant was separated from the old by over a mile. One day the whole works will be on the new site, for the old site has been filled to its edges. About it are substantial homes, some built before the factory, for the days of restrictions are comparatively young.

Conditions That Are Preventable

An analysis of this episode reveals the following set of conditions that a proper town plan would both prevent and foresee:—

1. The depreciation of the residential section due to (a) the elevation of factory buildings; (b) the frequent unsightliness of factory buildings, and in most cases the incongruity of the juxtaposition of factory and residence; (c) in certain cases smoke, fumes, noise and even dust.

2. The loss to the industrial interests of the community by the scrapping of old plant that is never quite fit for anything else, and the building of a new plant.

The factory area should have been located at the beginning of the town's growth, but the beginning has long gone past and the duty of this day remains to make the best of conditions in the laying out of areas that will serve the best interests of the community and of industry.

The areas chosen should be selected in their relation to (1) railway facilities; (2) water frontage, where necessary; (3) prevailing winds; (4) land available in large blocks, unbroken by streets; (5) accessibility; and (6) most important of all, the worker's home.

Locations, indeed, may vary. A plant making breakfast food differs in location requirements from a cement works. In general, decision as to location should be reached in the light of the greatest advantage to the city as a whole. New factories should be placed where they belong, whatever the temptation may be to place them where they do not belong; and there always are such temptations. Industries already wrongly placed should be encouraged to remove to their proper areas; there is always the incentive of added efficiency from proper location.

Industrial Land Often Subdivided

Some of our municipalities, among them Port Colborne in the Niagara section, have purchased areas for industrial development, a very necessary step to preserve the land from the subdivider. In not a few other cases, land admirably located for factories has been divided into lots. Some may be built upon and the others owned by people living in the four corners of the globe. The divided ownership, the enhancement of the values through speculation, and the broken

streets, shut the property out forever from industrial possibilities.

If the town plan, however, has some salvation to offer to industry, and nothing to offer to the worker in the industry, it has utterly failed of its mission. The factory system is here with its load of problems, one of which arises out of the fact that half the people of our nation are urban dwellers. The town plan should aid industries on the one hand, and on the other secure an economical land development, with comfortable houses and healthful living conditions for the workers.

This kind of home for every wage-earner can be made possible only by a full and frank recognition of how intimately the housing question is connected with other immense problems of town planning such as (1) factory location, to which reference has just been made; (2) street systems; (3) local transportation; (4) facilities for recreation; and (5) restrictions.

Town Plan Not Enough

But the town plan is not big enough to solve the whole problem. The regional plan, calling in the co-operation of a whole group of municipalities, is the only means by which waterfronts, the picturesque, and the historical, may be capitalized for the people. These vantage points of the section, under the regional plan, in a way become the property of all, and thought and care can make them of recreational service to all.

If the house in rental or in purchase price takes too large a percentage of the worker's wage, the deficiency must be made good by a reduced standard of living.

The builder of Port Sunlight advocated the buying of land by municipalities, to be given to those who would build homes for themselves. We have bonused every conceivable kind of industry, but no one has yet proposed the bonusing of homes. Yet the bonusing of a home is not so crack-brained as the bonusing of an industry. One bonus we can give, and that is the guarantee that the surroundings of every home will remain permanently good.

Thomas Adams, in a recent article on "Canada's Post-War Housing Progress," quotes the considered opinion of two well-informed observers as to the housing policy which has been adopted in this country, and which is not federal, provincial or municipal, but a combination of all three. C. Stanley Taylor, project engineer for the firm of Mann & MacNeille, New York, who were advisers to the United States government on many of their housing projects, states: "We wish to express our unqualified admiration for the completeness, practicability and simplicity of the administration methods of the Canadian plan.. We believe this to be the most practical step toward the provision of good housing by federal co-operation which has yet been taken in any country."

The city engineer of Edinburgh states that the Canadian project is on sounder economic lines than the proposed housing schemes in Britain.

K. V. Haymaker, of the Department of Labor, Washington, says that the difficulty in the way of more and better homes is financial. No solution short of a nation-wide solution is satisfactory. The house starvation of the nation cannot depend upon casual financing for alleviation. The local association, helpful as it has been, always falls down when its help is most needed.

"By-Products" of Good Housing

I mention these outside judgments because I believe we have started to answer the housing question on the right lines, and if we supplement the Housing Act in our own municipalities with provisions that will ensure to the home builder a non-impairment of his investment, and healthful and beautiful surroundings, we have gone a long way toward making our towns and cities fit places in which to live.

The fruits of the effort will not be good houses, alone, but, what is more important, good homes. Good homes make good towns and cities and good industries,—and out of it all will grow a good Canada.

For the young Canadian the gain will be more than for the old. The boys of Bournville at twelve years of age average 8½ lbs. heavier than those at St. Bartholomew's ward in Birmingham, and the girls a bit more than that again; and both boys and girls average nearly 3 ins. taller than those of St. Bartholomew's. The infant mortality rate is little more than half that of London.

A good house is more than a good house. It means also a good standard of living; it quickens the life, and it draws men and women, and little men and women, up to the light of better things. For what else do we live?

FOUR DAMS PROPOSED FOR ST. LAWRENCE RIVER

THE plans for the prospective development of the St. Lawrence-Great Lakes route for ocean navigation provide for four dams and concentration basins,—at Morrisburg, Cornwall, Lake St. Francis and below the Lachine Rapids. Extensive borings are now being made to determine the best sites. The first two dams would be international, and the others in the province of Quebec. It is stated that at least 3,000,000 h.p. could be developed. These dams would create a deep water channel between them for ocean vessels, but at each dam locks would be required as large as those being constructed on the new Welland Ship Canal, and near Montreal there would have to be a new canal system. Engineering problems which the Dominion Power Board is endeavoring to solve are the location of these dams so as to obviate ice-jams; extensive dyking against flooding of low-lying lands in Huntingdon county, Quebec; ascertaining the effect which the new plan, when completed, would have on the flow of the Ottawa River; and the fixing of a water velocity suitable both for navigation and power production.

PROPOSED DEVELOPMENT OF HAMILTON HARBOR

(Continued from page 540)

areas on the marginal way and to the south of it are for warehousing and light manufacturing where ready access to the water and shipping is desirable and rail shipment facilities are imperative. In the district to the south of the marginal way, all properties are served at the rear by trackage, leaving streets clear of obstructions for approaches and teaming.

The extreme easterly end of the district is served with a ship channel and turning basin, marking a clear-cut line between the industrial area and the beach development, as well as affording an increased area of waterfront property. Rail shipments in and out of the district are handled through a sorting yard, 58 acres in extent, located between Martimas street and Kenilworth avenue, and connected up with existing rail lines.

To carry out this proposal, certain properties would have to be acquired outright. In other cases, the commission could probably, by negotiation, arrange for a waiving of riparian rights in return for reclamation of water lots and docking privileges, but in any case it is not apparent where any serious obstructions would arise.

Coming to the question of cost, it is necessary to consider the length of time that would elapse before the entire work would be completed, and try to relate this in some way to the present uncertainty of labor conditions and costs of materials. Obviously this is quite impossible, as manufacturers will not quote prices except for immediate delivery and the wages paid to labor are constantly changing. A perusal of the price fluctuations during the past four years would show that an estimate made in 1914 would look absurd when applied to present conditions, and is sufficient evidence of what might happen during the next fifteen years, or the period of time over which the carrying out of this improvement might reasonably be expected to extend. In view of this, I thought it wise to recommend for immediate consideration the development of the industrial section between Wellington street and Wentworth street, for which the Dominion government has already made an initial appropriation of $100,000, and estimated the cost accordingly.

This area extends to the revetment wall at the foot of Wellington street, but the dock running north and south at that location could be left available for some time by allowing the reclamation material to take a natural slope on the westerly side, leaving the slip open. When conditions warrant (that is, when the area now set aside for a slip could be used to better advantage for manufacturing sites), the steel sheet piling forming the face of the government wall could be withdrawn and salvaged, thus minimizing the loss occasioned by abandoning the layout at present existing.

The main items entering into the cost of this section of the development are as follows:—

Construction of retaining wall	$ 980,000
Acquisition of property	103,000
Reclamation	933,500
Total	$2,016,500

This would put the commission in possession of an additional 97.07 acres of industrial property, exclusive of streets and track allowance, that could in the near future be utilized for factory and warehouse sites.

Burlington beach and the north shore of the harbor by their physiography lend themselves admirably to æsthetic treatment, and the proposed development along these frontages is largely for park, amusement and residential purposes. It might be argued that this phase of the proposal is not essential, but from a study of the prevailing conditions in other large centres, the writer is firmly convinced that no waterfront development is complete, or adequately meets the requirements of a large industrial city, if ample provision be not made for recreation purposes.

The sketch showing the typical cross section of the beach development (see illustration above), provides for the elimination of rail traffic on the beach road and concentrates power transmission lines and electric and steam roads on an elevated viaduct located approximately on the present Grand Trunk right-of-way. This viaduct could commence to rise on an easy grade in the vicinity of the Grand Trunk crossing at Burlington street, and the tracks could be elevated the entire length of the beach, striking the high ground and coming out on the level again in the vicinity of Brant House, Burlington. The elevation of these public services rids the beach of its objectionable features from the standpoint of a parking and playground treatment, permits free access to the lake beach from the boulevard drive, and may be incorporated in the layout proposed by the Tye-Cauchon report on the railway situation at Hamilton. The entire rail service accommodation suggested herein was planned with the probability in mind of the early electrification of steam roads in Hamilton.

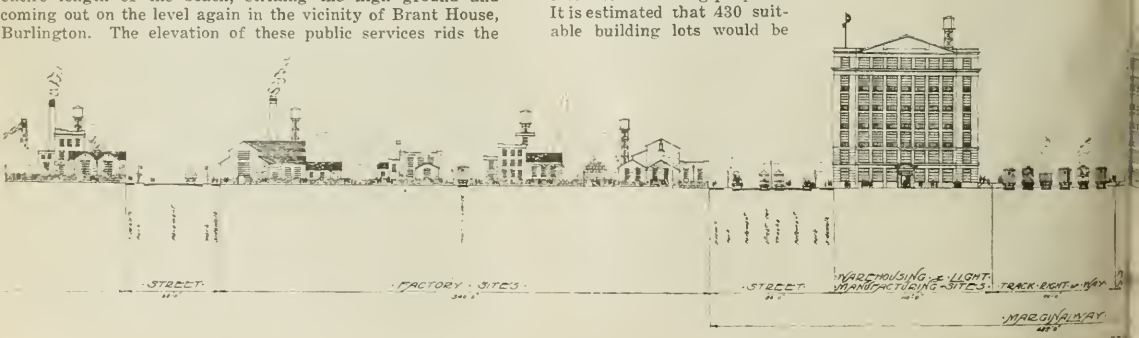
It was thought desirable to increase the beach area in order to provide greater accommodation, and soundings and borings revealed the presence of suitable material in sufficient quantity to more than effect the reclamation planned. A lagoon treatment is used along the frontages of the existing property, and the created lands are made accessible by artistic concrete foot bridges at strategical points and vehicular service bridges where required. Locations are suggested for bath houses, public parks, playgrounds, amusement centres, aquatic clubs and residences. There is also provision made for a promenade board-walk along the lake frontage of the beach, protected by a large sloping sand area extending to the water's edge.

Cross Section of Hamilton Beach in the Vici

Typical Cross Section of Hamilton Bea

It will be noted that no plans have been made for breakwater protection in the lake, it being impossible at this time to estimate the extent or location of the possible requirements. This can only be determined after careful observation of the effect of the waves and currents on the beach, after same has been reclaimed, but since the formation of Burlington beach is the result of a natural accretion, it is not expected that serious erosion will take place.

For the reasons outlined in connection with the industrial district, I estimated only the cost of the reclamation on the bay side of the beach to the south of the canal, which is the section that would in all probability be first undertaken. This comprises an additional area of 172 acres, 85 of which has been subdivided into lots for leasing purposes. It is estimated that 430 suitable building lots would be



Cross Section at the Foot of Wellington Street, H

available, allowing 50 ft. frontage to each, which, when coupled up with the returns from amusement privileges, should yield an annual income of approximately $75,000. The control of the present beach should be transferred to the Hamilton Harbor Commission before improvements are undertaken, so that the resulting revenues could be applied against the interest and sinking fund charges on the capital expenditure.

The items entering into the cost of this section of the development are as follows:—

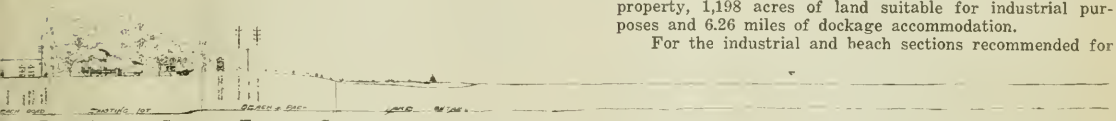
Reclamation	$1,486,000
Bridges	300,000
Channel wall at south end	700,000
Total	$2,486,000

the north side of the harbor over the right-of-way already largely dedicated, while the other section follows the water's edge on the parkway and beach to be reclaimed by hydraulic dredging at the foot of the cliffs. The two branches merge again at the west end of the harbor, where it is proposed to reclaim the low-lying marsh lands as another park area. The boulevard then continues along Harvey and Dundurn parks to connect through the city with Burlington street again.

The total length of this boulevard drive is 16.98 miles, 10.59 miles of which traverse parks or are over lands commanding a harbor outlook.

The completion of the entire work will leave Hamilton harbor with an area of 4,380 acres, or 6.8 square miles, having a governing depth for navigation of 30 ft., as compared with the present 4,500 acres, having a depth of 18 ft. There will be added 1,250 acres of park and residential property, 1,198 acres of land suitable for industrial purposes and 6.26 miles of dockage accommodation.

For the industrial and beach sections recommended for



RTH PARK AVENUE, SHOWING EXISTING CONDITIONS

COMPLETION OF PROPOSED DEVELOPMENT

The construction of roadways, sewers, water services, etc., would be taken care of in the cost as a local improvement, while the grade separation would be a matter of adjustment by the Board of Railway Commissioners between the city, the railway companies and any other interested parties.

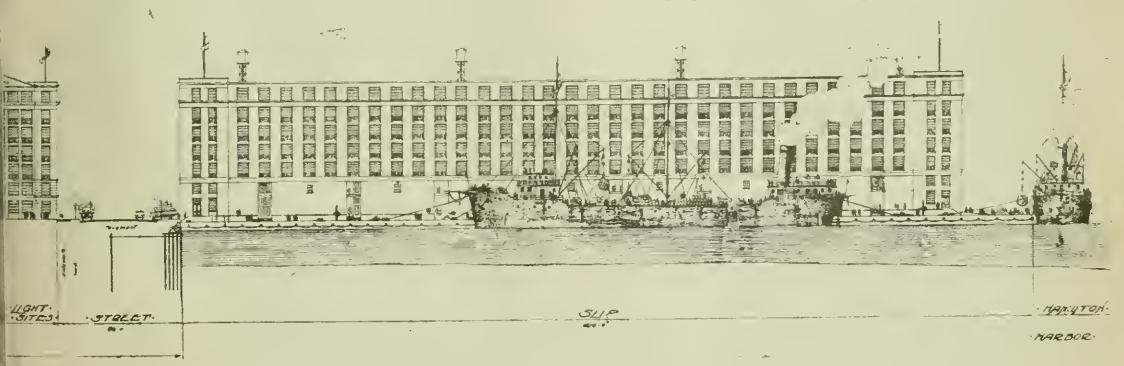
Burlington street, as before pointed out, forms the backbone of the industrial district, and through its connection with the east and west ends of Hamilton, is the logical connecting link for a boulevard drive around the harbor. This thoroughfare should be widened to 86 ft. and connected up at the east end with the beach road. The beach road, having been freed of rail traffic, carries the boulevard to the channel crossing, where the Dominion government has in contemplation the construction of a bascule bridge to span a 300-ft. opening instead of the present 150-ft. channel.

Continuing in a northerly direction along the beach road, the boulevard swings to the west near Brant House, where it divides. One section is carried along the high ground on

immediate consideration, the total estimated cost is $4,502,500 which should be apportioned among the parties interested—viz., the Dominion government, the city of Hamilton and the Hamilton Harbor Commission.

It has been intimated that the people of Hamilton would expect the Dominion government to bear the expense of the construction of the dock walls, at an estimated cost of $980,000, and to deed to the Hamilton Harbor Commission all water lots now vested in the Crown; also to pay the cost of the wall on the beach side of the channel and turning basin, which forms a part of the industrial district, at an approximate cost of $700,000.

The city of Hamilton should be asked to pay the cost of acquisition of all properties required, and to deed the same to the Hamilton Harbor Commission, at a cost of $103,000, and to pay for the reclamation of the park areas on the beach, at an estimated cost of $500,000. The city should also be asked to transfer to the commission all waterfront properties which the city now owns or controls.



HOWING TYPICAL PROPOSED INDUSTRIAL DEVELOPMENT

The Hamilton Harbor Commission would then have to finance the reclamation of the industrial areas and the revenue-producing section of the beach, including necessary bridges, at a cost of approximately $2,219,500.

This scheme would put the commission in possession of assets that would enable it to carry on the industrial development planned.

The length of time that it would take to see the entire undertaking completed depends entirely upon the financial support accorded it and the aggressiveness of the administration, but I have no doubt that if the work recommended for immediate consideration be gone on with now, the advantages that will result to the city of Hamilton and to the country as a whole, will commend themselves in such a way as to bring the entire scheme of waterfront and harbor development to an early realization.

Valuable services were rendered by J. E. Hollaman in conducting surveys and in the preparation of the plans, and consulting advice on parking and boulevard treatment by Jas. J. McKay. By the courtesy of the Toronto Harbor Commission, in order to obtain the benefit of their experience on their $25,000,000 waterfront improvement now under construction, it was possible to have E. L. Cousins, their chief engineer and manager, exercise a consulting supervision over the entire investigation.

PARRY SOUND WATER WORKS

Report by Consulting Engineers Favors Mill Lake as the Source of the Town's Future Water Supply—History of the Water Works

IN a report recently made by Chipman & Power, consulting engineers, Toronto, upon the proposed water works extensions and improvements at Parry Sound, Ont., a brief history of the original water works system and subsequent developments is related, present conditions are discussed, and recommendations are made regarding the best source of supply. The following information is abstracted from the report:—

The original system, designed in 1892 by John Galt for a population of 1,700 people, consisted of an intake pipe, pump house and residence for the operator, one steam pump, one boiler, an elevated storage tank and about five miles of distributing mains, with five hydrants and gate valves. The distribution system was extended year by year as demands arose. In 1904, a vertical triplex pump, driven by an electric motor, was installed, and in 1915 a larger elevated storage tank was erected beside the old one. The steel tank erected in 1892 is 16 ft. in diameter, 20 ft. in height, and contains 25,000 gals.; and that built in 1915 is 36 ft. in diameter, 18 ft. high, and has a capacity of 116,400 gals.

The present water supply is drawn from the harbor, and is polluted, as the Seguin river, which flows through the town, carries the sewage and street drainage into the harbor. The factories along the shore contribute to the pollution, particularly as the drainage from an iron smelting plant and a chemical works discharge within 300 yds. of the intake. The only purification of this water is effected by chlorination.

The present conditions are summarized as follows:—

1. The present water supply is polluted, and such pollution will probably increase.

2. The steam pumping plant is old and inefficient, and the pumping capacity must be increased.

3. A new pump house is required.

4. Distribution mains from the pumping station to the business section of the town are too small to give proper fire service.

The population of Parry Sound is now approximately 4,000, and the average daily water consumption for the entire year is estimated as about 300,000 gals., increasing in summer to a peak of 700,000 gals. per day, or the full capacity of the triplex pump. For a town of 4,000 population the fire underwriters require four fire streams, or about 800 gals. per min., which, added to the peak domestic supply, gives a total of 1,300 gals. per min. as the present requirements. In the opinion of the engineers, those portions of the works that cannot be extended or enlarged without the sacrifice of constructed works, should be of ample capacity for double the population, or for about 9,000 people. Upon this assumption, the normal domestic consumption would be about 700,000 gals. per day, the peak in the summer should not exceed 1,000 gals. per min., and the fire service required would be 1,400 gals. per min., making a total of 2,400 gals. per min. during fires.

Three Sources Considered

The engineers gave consideration to three sources of supply: (1) Parry sound; (2) Mill lake; and (3) Trout lake.

The area of the waters of Parry sound from Kill Bear Point to Rose Point, is approximately 24 sq. miles. The entrance to it from the west is navigable for vessels drawing 25 ft., and the sound itself could float the navies of the world. The maximum depth is 360 ft., this point being distant only two miles due west from the water works pump house, and one-third of a mile north of Three Mile Point on Parry island. The shores of the sound are of solid rock, with an occasional sand beach at the head of a bay. The Seguin river discharges into the south end of the sound, and along the north shore there emerge a few small brooks.

With the exception of the town of Parry Sound on the east, the Nobel explosive factory on the north, and the G.T.R. terminus of Depot Harbor on the south, the shores of Parry sound are uninhabited, and there is practically no agricultural land immediately back from the shore.

The entire population of the country along the shores of the sound, including the places above mentioned, at the present time does not exceed 5,000 people, and the town of Parry Sound, and the Nobel plant, are the only serious factors in the possible pollution of the water. The former is the only one that seriously affects the existing source of water supply.

At a distance of about half-a-mile due west from the water works pumping station, the depth of water is given on government chart as 210 ft. Intake pipes of greater length than this have been laid in Canada, but the engineers state that they do not know of any place in Canada or in the United States where a water works intake has been laid in a depth of water much exceeding 100 ft.

The bed of the sound is overlaid with a soft mud, that would bury any pipe laid along the bottom. It would be practicable to lay an intake with screen in 200 ft. depth of water, but it would be very expensive to repair such pipe if it should be accidentally broken or if it should draw apart at a joint. It could be tested at any time to determine if it had drawn apart, and it could be flushed out. Leaks, however, would be difficult to locate, and impossible to repair excepting by lifting the pipe above the surface of the ice in the winter months.

Pollution by Town's Sewage

At a depth of 200 ft. the temperature of the water would be lower than at the existing water works intake, and would therefore be less affected by warmer surface water during the summer months. When covered with ice, the water at the surface would be cooler, and it is probable that the general pollution would extend to the deepest points.

The location of the present pumping station was selected when the bay water was less polluted, and was undoubtedly the cheapest and best location when the cost of force main to the town is taken into consideration. To move the pumping station up the shore towards Bower's bay would involve a heavy expenditure for force main, as the excavation would be through solid rock for practically the entire distance.

The sewage from the town, now discharged into the Seguin river, is carried into the southerly part of the harbor and then, by the agency of currents and winds, the pollution is diffused. The engineers state that the greater the distance the intake be located from the mouth of the river, the less the degree of pollution. They are of opinion that the water from the present intake, or from an intake in that vicinity,

can be so purified by filtration, followed by chlorination, as to be safe for all domestic purposes.

If the harbor be retained as the source of supply, it will be necessary to treat the domestic sewage before discharging it into the river, and also to collect the sewage from a small, but important area near the pump house, and pump it over the hill to an outlet into sewers now flowing into the river. The first cost of the sewage disposal plant will depend upon the degree of purification necessary. Probably sedimentation tanks, and chlorine disinfection, will be considered satisfactory by the health authorities. The solids deposited in the tanks may amount to four tons per million gallons of sewage treated, all of which must be periodically removed and disposed of in some way. To collect the solids, and then discharge them into the river when it is in flood, would not give satisfactory results, but this might be done by an employee without the knowledge of the health officials, and the source of water supply seriously polluted. By chlorination, the bacteria in the sewage can be destroyed, but the dose must be a heavy one, say 50 to 100 lbs. of liquid chlorine for each million of gallons treated, or an average of about 35 lbs. per day.

Liquid Chlorine More Efficient

About 18 lbs. of hypo-chlorite of lime solution per million gals. are now used for sterilizing the water supply. Less than 3 lbs. of liquid chlorine would effect the same results as this quantity of lime. If hypo-chlorite of lime solution were used for disinfecting the sewage, it would require an average of 210 lbs. per day. The annual cost for chemicals for disinfecting the sewage, would therefore be about $6 a day, to which must be added the labor of attendants, say $1 a day, and the cost of the removal of the sludge. The total annual expense in connection with treating the sewage at the present time would amount to at least $3,000 per annum. Pumping the sewage from the area contiguous to the water works pumping station would cost about $600 per annum.

Mill lake is an expansion of the Seguin river, the outlet being distant 300 yds. from the north-east limit of the town. The lake is roughly circular, with an area of 1,100 acres. The Seguin river enters the lake from the north and discharges at the south-west angle. Another large stream enters the lake at the south-east angle.

The drainage area of the Seguin river above Mountain dam is given in a report of the Ontario Hydro-Electric Power Commission as 380 sq. miles. The annual run-off on this drainage area is given as 622 cu. ft. per sec., with a recorded minimum of 33 cu. ft. per sec., in September, 1917, and a maximum in April of 3,620 cu. ft. per sec. There is an additional area, tributary to Mill lake, which would increase the total to over 400 sq. miles. Practically all the land within the watershed consists of low ranges of solid rock, with swampy valleys between, which are scantily timbered. There are many lakes and ponds in the watershed, and at several points dams have been erected for controlling the water.

At the foot of Mill lake a timber dam was constructed many years ago, the height of the crest being 10 ft. above the slack water below. This dam raised the water in Mill lake about 8 ft., and flooded considerable low land from which the standing timber has been removed. The town has acquired this dam and other dams at various points on the river.

Fewer Dangerous Bacteria

On the main stream, about three miles north from Mill lake, another timber dam exists, called the Mountain dam, with a height of 25 ft., and on the south branch, one mile south of Mill lake, a dam 5 ft. in height controls the water. Another important dam is at the foot of Lake Waubeck. In all, there are about five substantial dams and several minor dams for controlling the water within the watershed, but none are being used directly for power purposes.

Early in the summer the lakes and ponds are full, and the dams overflowing. In the autumn and winter the stoplogs are removed and the water drawn down. In the early spring the lakes and ponds are refilled. Swampy areas have been flooded by these dams, and the water of the Seguin has consequently acquired a swampy taste that is disagreeable. In color the water is brown, similar to that in the Ottawa river. It will probably be found to be much softer than Parry sound water, say the consulting engineers, and therefore more satisfactory for laundries, bathing, boilers, etc.

Bacteriologically, the Mill lake water will probably show a greater number of bacteria, they say, but fewer dangerous bacteria of the typhoid group than does the present source of supply. Mill lake has an elevation of 52 ft. above Georgian Bay. A contract has been awarded for a new concrete dam to replace the old timber dam.

Filtration, Chlorination and Aeration

Filtration and chlorination will render this water safe for domestic purposes, and some of the color will be removed by the filters, but there may be some difficulty in removing the disagreeable taste. In some places this has been accomplished by aeration.

As compared with the water in Parry Sound, the water from Mill lake will be darker in color, warmer in summer, softer, but occasionally swampy in taste. It will also be a safer water from the public health standpoint. The engineers state that they cannot assume the responsibility of recommending the taking of the supply from the Seguin river below Mill lake, owing to the number of nuisances that now exist along the river bank, and the possibility of factories or buildings being erected that will drain into the river. This river bank could, however, be cleaned up, and as it is now owned by the government, it is probable that it could be protected from future pollution. The danger of sewage pollution from the Mill lake area may be considered as negligible, but in order to prevent contamination, a strict surveillance of the lake shore will be necessary, if it should be selected as the source of supply.

The size of the conduit necessary to convey the water from Mill lake to the pumping station at the power house will depend on the height at which the water in the lake is to be maintained. With a 24-in. conduit, the discharge at the pump house would be 1,630 gals. per min. with the water in the lake drawn down 7 ft. below the crest of Mill lake dam, 2,240 gals. if drawn down 5 ft., and 2,650 gals. if lowered 3 ft. The engineers are of opinion that the lake will seldom be lowered more than 5 ft. With this head, a 20-in. conduit would deliver 1,450 gals. per min., and an 18-in. pipe 1,100 gals. per min.

In the Mill lake scheme, by reducing the diameter of the conduit from 24 ins. to 18 ins., the capacity would be decreased by about one-half, and if Mill lake were drawn down a few feet, the discharge would not be sufficient for fire service, and it would then be necessary to supplement it by pumping from the power house fore-bay.

The engineers state, therefore, that they would not advise that the conduit be made less than 20 ins. in diameter. This will discharge 1,100 gals. per min., with Mill lake lowered 7 ft.

The Trout Lake Scheme

Trout lake is distant about two and one-half miles in a straight line north from Mill lake. The area of the lake is about 660 acres, and the area of its tributary watershed 1,340 acres, in addition to the lake surface. The greater part of the shore line is rock, and one sounding gave a depth of 45 ft. The water in this lake is clear, quite a contrast to the amber-colored waters of the Seguin river and Mill lake, and was found free from pollution.

The lake discharges normally to the southward, but in high water it overflows eastward through a ditch; both outlets eventually discharge into the Seguin river.

At the main outlet, the stream falls about 30 ft. in a distance of about a half-mile, entering a small pond. Leaving this, the water flows through a rocky canyon, with a fall of 140 ft. in less than a mile. The elevation of Trout lake is 250 ft. above Georgian Bay, and 40 ft. above the top of the existing steel water tank.

The length of gravity conduit necessary to convey Trout lake water to the power house would be about 32,000 ft., and about 5,000 ft. length additional main required from the

power house to the tank. If a 12-in. conduit were laid throughout, it would deliver about 1,000 gals. per min. at the power house, and 450 gals. per min. into the water tank. The discharge would be doubled by using a 16-in. conduit. A satisfactory domestic supply could be given for some years by gravity through a 12-in. conduit, but for fire service, pumping would be necessary. Should the domestic demand increase the peak above 500 gals. per min., it would be necessary to boost the pressure by pumping.

Gravity Type Filter Plant

If a 16-in. pipe were used, it would give domestic service without pumping for many years, but pumping would be necessary for fires and for domestic service whenever the peak demand exceeds 1,000 gals. per min., or at the rate of 1,440,000 gals. per day. The peak hourly domestic demand in the summer months is now about 600 gals. per min. and will increase with the population.

The quality of the water in Trout lake is satisfactory, and its elevation sufficient to give a domestic service by gravity. The clearness of the water is due to the small watershed as compared with the lake surface, and the rocky character of the country.

At Toronto the average annual rainfall is 34 ins., the minimum 24 ins.. while at Parry Sound the average rainfall is 40 ins., and the minimum recorded in 27 years is 31 ins. The engineers state, therefore, that they can only safely assume that one-third of the rainfall on the land surface can be impounded in the lake. The evaporation from the lake surface will probably slightly exceed the rainfall on it. Assuming that in a dry season, 10 ins. of water can be impounded from the 1,340 acres, this will give an average daily yield of about 840,000 gals., or 583 gals. per min. The storage in the lake would be sufficient to guarantee a supply for about 8,000 people, with services unmetered, but by general metering of services, Trout lake might be depended upon to supply 12,000 people.

The engineers' estimates are for a rapid sand filter of the gravity type, with a capacity of 800,000 gals. per 24 hrs. The filter comprises four units each of 200,000 gals. capacity, one of which may be cut out for renewals or repairs, as the remaining three will be sufficient to deal with the maximum daily consumption. As the turbidity of Mill lake or Parry sound is never high, a much greater volume of water can be filtered, per square foot of filter area, than of more turbid river waters, or even Lake Ontario water at Toronto after gales.

Advantages Over Pressure Type

The filters will be superimposed over the clear water basin, and space provided in the filter house for storage of chemicals. Pressure filters are satisfactory, say the engineers, when not overtaxed or mismanaged, but the gravity type has these advantages:—

1. Their operation can be observed.
2. Removals and repairs can be more readily made.
3. The head can be varied with the condition of the sand or of the water.
4. More uniform and more satisfactory results can be attained.

If pressure filters be substituted for gravity filters, the cost of the Parry sound scheme or the Mill lake scheme might be reduced by $5,000 but the engineers do not advise this.

The report states that the expenses of operating the present water supply are approximately as follows: Salaries and wages, $2,500; electric power and fuel, $2,000; maintenance and repairs, $500; house services, $500; making a total of $5,500. The fixed charges amount to $5,000, giving a total expenditure of $10,500. The revenue from fire protection is $3,200; from schools and municipal use, $250; and from general consumers, $9,550; totalling $13,000. The engineers are of the opinion that the charges for maintenance and repairs are too low, and that no allowance has been made for depreciation.

The estimated cost of the new scheme is $107,000, and includes the following items: Land and right-of-way, $1,000; intake, 20 ins., 1,000 ft. long, $10,000; pump well and pump house, $6,000; power transmission lines, $4,000; two pumps, 750 gals., with motor, etc., $10,000; pumps and pipes to filters, $9,000; coagulating basin, 120,000 gals., $7,000; filters, capacity 800,000 gals. a day, $15,000; filter house, $5,000; 400,000 gals. reservoir, $15,000; venturi meter and chlorinator, $2,500; and new mains, $22,500.

As the existing intake from the pump house to Parry sound is of sufficient capacity for present requirements, the proposed new intake may be deferred for a few years, and, if this be omitted the estimate will be decreased by $10,000.

An annual expenditure of $19,970 will be made up as follows: Operating charges, $7,700; fixed charges, $12,270. The latter include $5,000 on existing works and $7,270 on new works and assume that debentures for these improvements will run for 30 years at 6% interest.

Estimates of Expense

To meet this expenditure it would be necessary to increase the annual revenue by about $7,470, besides taking care of the fixed and operating charges in connection with the sewage disposal works.

It is estimated that the Mill lake scheme will cost $128,000, as follows: Land and right-of-way, $2,000; 24-in. conduit from Mill lake to power house, $45,000; coagulating basin, filter equipment, reservoir, venturi and chlorinator, $44,500; pump house, $4,000; three pumps, each 750 gals., $13,000; and 12-in. force main, $19,500.

The cost of operation will be approximately $7,600; the fixed charges on old works, $5,000; and on new works, $9,300; making a total annual expenditure of $21,900. This scheme will necessitate an increase in the revenue of $9,400. By adopting a 20-in. pipe instead of a 24-in. one, the first cost will be reduced by $6,000 and the fixed charges lessened by $435 per annum.

The third scheme, that of obtaining water from Trout lake, is more expensive, and will probably cost $272,000, including the following items: Dams and head works at Trout lake, $12,000; 16-in. cast-iron main, $129,000; excavating and laying pipe, $48,000; additional cost for rock excavation, $30,000; reservoir, pumps and pump house, $32,000; and force main, $19,000. If wood-stave pipe be substituted for the cast-iron pipe estimated upon, the cost will be reduced by $30,000, or possibly $35,000.

The annual cost of operating the Trout lake scheme amounts to $4,200, and is less than either of the others, as pumping would only be necessary during fires. The fixed charges on old works are $5,000; on new works, $19,740; making a total of $28,940, which exceeds the revenue by $16,440. By using wood-stave pipe, the annual reduction in the fixed charges would be $2,180.

The conclusions arrived at by the consulting engineers are as follows:—

Conclusions

In the Parry sound scheme, the annual operating costs and fixed charges will be slightly higher than in the Mill lake scheme, but the difference is so trifling that it is not a factor in deciding between the two schemes. The Trout lake project would prove too expensive, and the yield from the watershed might not prove sufficient for the future requirements of the town. For the present, Parry sound water, filtered and chlorinated, would be a safe, wholesome water, cold, clear and palatable, and more acceptable to the citizens than Mill lake water. The Parry sound water, however, is now polluted with sewage, and this pollution will increase. Even if the sewage be treated, there will always be a danger of untreated sewage, or of sludge, being discharged into the river below the power house, and carried into the sound.

The water in Mill lake is contaminated by vegetable growths, which render it objectionable in its raw state. The flooded lands within the watershed of the Seguin river no doubt increase the natural contamination, but it is improbable that this will be further intensified, and it is not so dangerous as the Parry sound water, which is polluted by sewage.

Filtration will improve the quality of the Mill lake water, remove the organic vegetable matter, and render it safe to drink at all times. The analyses and examinations

which are being made by the health authorities should demonstrate whether it is possible to remove entirely the disagreeable tastes and odors.

After treatment, Mill lake water will be preferable to Parry sound water for practically all industrial uses, steam boilers, heating plants, laundry purposes, etc., but will not be so palatable as Parry sound water.

Taking the future development of the town into consideration, the engineers favor Mill lake as the source of future water supply.

STEEL CO. IMPROVES PUMPING FACILITIES

BY constructing an earthen dyke, 4,000 ft. long, around the eastern end of Grand lake, thus creating a new basin 5 ft. higher than was previously possible, the Dominion Iron & Steel Co., of Sydney, N.S., has increased the water area of the lake from 180 to 390 acres. This was necessary in order to secure an adequate supply of fresh water for the steadily growing steel company, who, during the last year, have installed a large coal washing plant and two modern batteries of Kopper's coke-ovens. The old spillway at the outlet has been replaced by a new 94-ft. spillway of substantial design.

The enlarged area which will hereafter be under water made necessary the relocating and rebuilding of two and a-half miles of the Sydney & Louisburg Railway Co.'s tracks between Victoria Junction and the steel company's assembly yard, the installation of new reinforced concrete culverts, new telegraph and telephone lines and a new water tank. The work also involved the raising—for a distance of 2,000 ft.—of the Sydney and Glace Bay Railway Co.'s tracks, as well as the power lines of that company.

An interesting feature in connection with this part of the work is that the alterations to the Sydney & Louisburg and the tram company's railway systems were effected without any delay or interference to the operations of their regular train or tram service. These changes in the track and pole lines required excavation of 80,000 cu. yds. of earth and rock.

The steam pumping equipment formerly in use, installed in 1910, has now been replaced by three new DeLaval electrically driven centrifugal pumps, each with a capacity of 4,000,000 gallons daily. Two of these units are expected to be in constant service. The third is a spare. These pumps are housed in a new fireproof building.

The connecting of the old water main to the new pump house required the raising and relocating of 3,200 ft. of the old 20-in. pipe line, but the change was made with only a slight interruption to the water supply of the Sydney coke plant.

The new elevation of Grand lake is about 100 ft. above the sea level. The increase of 5 ft. over the former level results in the total storage capacity being enlarged by 625,000,000 gals.

Steps have been taken to organize the municipalities in the Niagara district for the purpose of holding a "Niagara District Industrial Conference" next summer.

Since the federal government's purchase of the C.N.R., several provincial governments owning railway lines have endeavored to sell them to the Dominion cabinet. The New Brunswick government would like to dispose of the Valley Railway, while Alberta is ready to sell the Great Waterways, and British Columbia is anxious to part with the Pacific Great Eastern.

Estimated originally at about $5,000,000, the new Parliament buildings at Ottawa are expected to cost at least $8,000,000. This increase is mostly due to the rising cost of labor and materials, one and a half millions being charged up to the former and one million to the latter. Delays on the work are responsible for another half million. Definite instructions have been given that the buildings must be ready for temporary occupation at the February session of parliament.

Letter to the Editor

TRADE UNIONISM AND ENGINEERS

Sir,—After careful perusal of the article entitled, "No Room for Trade Unionism in Engineering Profession, Say Directors of American Association of Engineers," published in your issue of November 27th, 1919, the writer wishes to make these comments:—

The substance and reasoning tend towards an idealism of which the engineering profession already has too much, and appear to be the conclusions of the ultra clever and brilliant of the profession, who, either by hard labor or circumstances, have reached the pinnacle where remuneration or the struggle for existence ceases to bother them. They represent, so to speak, the capitalistic class of the profession.

To the vast multitude, the unnumbered hosts of the profession, the writer believes the conclusions expressed do not apply. In discussing methods, the term, "dignity of the profession," is used. Where, let me ask, is this "professional dignity," on construction works on which the professional engineers and inspectors (for engineers sometimes have to be inspectors) receive less remuneration than foremen and other labor-trade men?

These are conditions which should not exist unless engineers of this class are merely to render service to society.

Is the professional engineer not a laborer? He usually toils, not eight but fifteen or sixteen hours a day. He is no more nor less than an educated and specialized laborer. Why, then, should other laborers have unions and associations in which they are allowed to have at least some voice as to what the products of their efforts are worth, while the engineer stands alone, like a mendicant, and is compelled to take whatever his employer feels like giving him.

In the struggle for existence all laborers must necessarily co-operate and work together towards one end—viz., to make this world of ours a better place to live in. The artisans and laborers, less educated than professional engineers, have taken the lead by organizing and banding themselves together with advantage. Unionism, although it has faults, has advanced the status of these organizations and has placed some of their members in parliaments.

If our great professional body cannot evolve some policy for the betterment of its members as a whole, why not adopt labor unionism as it is, and then apply ourselves to elevate it, not only for our own benefaction, but for the welfare of all laborers, and strive to blend all classes together, until we reach the time when strife and strikes shall be no more?

FRED CHRISTIE.

Peterborough, Ont., December 11th, 1919.

The Midland district of the Department of Public Works of Canada has been added to the Central Ontario district, of which John M. Wilson is engineer in charge. This action was taken this week, after the death of Mr. Armstrong, who was district engineer at Midland.

N. Quesnal and James T. Lewis, both of the John Inglis Co., Toronto, will address the Ontario section of the American Society of Mechanical Engineers this evening (December 18th) at the Engineers' Club, Toronto. Their subject will be "Thirty Years' Progress in Boiler Construction in Canada."

The proposed joint water scheme for the border cities of Ontario (Windsor, Walkerville, Sandwich, Ojibway and Amherstburg) which will likely be voted on by the people of those municipalities at an early date, will cost about $2,100,000, according to the engineers' estimates. Of this amount $980,000 is required as compensation for the existing plants.

TWO NEW HYDRO-ELECTRIC POWER PLANTS FOR NOVA SCOTIA

THE Nova Scotia Power Commission has been authorized to proceed with the development of what are known locally as the Margaret's Bay water powers, about 20 miles from Halifax. The commission is undertaking immediately, and will carry forward as rapidly as possible, an initial development of about 8,000 h.p. It is probable that at a comparatively early date work will be undertaken at another site with an ultimate capacity of approximately 16,000 h.p.

NEW PREST-O-LITE PLANT AT TORONTO

THE Canadian National Carbon Co., Ltd., and the Prest-O-Lite Co., of Canada, Ltd., have jointly purchased ten acres at the corner of Bathurst street and Davenport road, Toronto, as a site for a new manufacturing plant. The new plant will consist of two buildings, one of which will be 80 by 400 ft., two stories high, with one section 80 by 80 ft., three stories high, to be occupied by the Canadian National Carbon Co., while the building for the Prest-O-Lite Co. will be 80 by 400 ft., two stories high. The heating plant will be housed in a separate structure, 50 by 60 ft., and will have room for installation of additional units.

All the buildings will be of reinforced concrete, with flat-slab floors and mushroom-type columns at 20-ft. centres, steel sash and brick curtain walls. The plant will be served by two switch tracks operated under a joint agreement between the Canadian Pacific and the Canadian National railways. It is expected that the plant will be ready for occupancy in May, 1920.

At present the two companies are operating five plants at different locations in Toronto. R. H. Combs, who has been general manager of the Prest-O-Lite Co. for the past three years, was also recently appointed general manager of the Canadian National Carbon Co. In addition to the plant described above, Mr. Combs states that the company will erect in the spring a new acetylene-gas plant in Toronto or vicinity, and a new storage-battery warehouse and assembly plant at Winnipeg. The contract for the Toronto plant has been awarded to Wells & Gray, of Toronto.

PROPOSED PETERBORO FILTER PLANT

PRELIMINARY plans and estimates of cost for a filter plant have been submitted by William Kennedy, Jr., consulting engineer, Montreal, to the Utilities Commission of Peterboro, Ont. The report states:—

"After a study of the quantity of water supplied to the town for the past few years, the quantity required at certain hours of the day, and especially during dry and hot spells of weather, together with possible heavy drafts of water for fire purposes during such dry and hot weather periods, also making allowance for an increase of population and water consumption, I have decided to recommend for first construction a mechanical gravity, sand filter plant of five million gallons' capacity per day, and in connection with this filter plant a covered reservoir of two million gallons' capacity.

"The filter plant will be designed for six million gallons' capacity per day in units of one million gallons to each filter unit, but five units only to be first installed, with the necessary connections made for the sixth unit when required.

"I may also mention that the plant is so designed as to permit of duplication of these six units, thus providing for an ultimate filter capacity of twelve million gallons daily.

"It is estimated that a five million gallons' plant will be sufficient for all purposes until the year 1925.

"The reservoir, containing filtered water, will have a present capacity of two million gallons, and is so designed and placed that its capacity may be increased to say four or five million gallons when so required.

"The additions to the filter plant or reservoir, or both, may be made without interfering with the water supply to the town.

"Full plans and specifications for the entire plant, including coagulating and clear water basins, low-lift pumps, etc., as above outlined, will be prepared, and from which tenders will be invited from contractors for the different classes of works, materials and equipment included. The whole of the necessary works and supply of materials, etc., will be divided into, say five contracts, but one contractor may undertake two or more contracts, or even the entire works required; or a part may be done by day work under the direction of your waterworks superintendent.

"The contracts may be divided about as follows:—

"1. Intake crib in river; intake pipe; suction well; construction work generally; and superstructure for filtration plant.

"2. Filter equipment.

"3. Low-lift pumping machinery; suction and discharge pipes within the building; electrical equipment.

"4. Outside pipe lines, including 24-in. discharge from the low-lift pumps; 30-in. conduit from clear water basin to pumping station, with valves, etc.; necessary sewers and drain connections.

"5. Two million gallon clear water reservoir.

"The specifications will also provide for receiving and the consideration of tenders for the entire filter plant from reputable contractors who may wish to make such modifications from the prepared plans and specifications as will suit their own designs and construction.

"It is intended to place the entire works on the Carnegie property recently acquired by your commission, except the pipe lines from the reservoir to the pumping station, which will run along the roadway.

"The estimated cost of the works above outlined is $300,000. More detailed plans may lower this estimate somewhat. My opinion is that the works, as per this report, can be built for the amount named.

"The main items in the cost of operation will be wages, fuel for heating purposes, power and chemicals.

"Assuming 3,600,000 gallons per day filtration, the estimated cost for operation—assuming chemicals at their present prices—is $10,700 per annum, or say, $8.15 per million gallons of filtered water, or assuming a population of 23,000, this is equal to say 47 cents per capita, interest and sinking fund not included."

The membership of the American Association of Engineers has passed the 10,000 mark, according to a bulletin sent out by the secretary of the association.

F. W. Thorold, consulting engineer, Toronto, is reporting on the water works system of Strathroy, Ont. The wells are not furnishing the amount of water expected, and it is anticipated that a new source of supply may have to be found.

A. D. Swan, Montreal, consulting engineer to the Vancouver Harbor Commission, has been instructed to proceed immediately with plans for the first unit of the proposed improvements, which will cost $5,000,000. Tenders for the initial work will be called for during the next six or eight weeks, it is said.

Members of the Manitoba branch of the Engineering Institute of Canada met December 9th in the Fort Garry Hotel, Winnipeg, and tendered a complimentary banquet to those of their number who have returned from overseas. The principal item on the program was the presentation by Brig.-Gen. H. N. Ruttan of an illuminated address to Capt. C. N. Mitchell, V.C., M.C. Following the silent toasting of the "glorious dead," T. R. Deacon proposed the toast to the guests, which was responded to by Maj. E. P. Featherstonhaugh, Lieut.-Col. R. H. Mulock, Maj. A. J. G. Taunton and Maj. C. W. Chivers. Short addresses were also given by Mayor C. F. Gray, Hon. G. Grierson and Isaac Campbell, a well-known lawyer.

PAVEMENT GUARANTEES

HEATED discussion followed the proposal made last February to the American Road Builders' Association by its committee on economic status of guarantees for pavements on roads and streets, that 10% of the contract price of new paving, and 20% of the contract price of resurfacing work, be retained by municipalities as a guarantee of satisfactory construction.

It was claimed by the paving contractors that serious injury would be done to their business as a result of the retention of such a large percentage of their contract price. The committee took these objections into consideration and decided that they could be practically eliminated by reducing the amount of the retained percentage to a point where the money retained would merely equal the reserve which the contractor might reasonably be expected to set aside to cover repairs.

From the committee's final report, published in *The Canadian Engineer* for November 27th, 1919, it will be noted that the amount of the guarantee was reduced from 10% to 5% for new construction, and from 20% to 8% for resurfacing, with the idea that the contractor should be paid immediately upon completion of his work all the money which he has expended in construction, together with a 10% profit.

Francis P. Smith, consulting paving engineer, New York City, advises us that the committee were of the opinion that if paving work be constructed with reasonable care, the percentage guarantee finally recommended by the committee would be sufficient to cover all ordinary repairs, and that it is inadvisable and nearly impossible to set aside a reserve sufficiently large to cover anything like a complete failure of pavements, and that protection against such contingency should come from the guarantee bond.

ENGINEERING WORK AT THE FRONT

CANADIAN engineers who saw active service with units in France are probably without knowledge of the doings of other "sappers," who served in Siberia; and officers and men who were sent to Italy have no idea what kind of work had to be done in India; those who were in Serbia have heard little of conditions in Gallipoli; sappers who encountered great heat in Mesopotamia would be interested to know the conditions that were met on the Archangel front. Each and every front of our expeditionary force had its own trials and met conditions peculiar to the part of the world in which it was engaged. Sappers were called upon, probably everywhere, to fulfil their functions as complete units or field companies, but there is no doubt but that individual sappers, or small parties of sappers, were often sent to perform some important work, away from the force and lines of communication, where unique difficulties were encountered.

It is suggested that it would be very interesting to all engineers, whether they have served overseas or not, to read short accounts of the experiences of sappers who have served on the different fronts. *The Canadian Engineer* would like to receive and will gladly pay for articles dealing with the different phases of sapper activity on the various fronts.

Those Canadian engineers who served with bridging trains in Palestine and Egypt could write valuable accounts of engineering operations prior to the capture of Jerusalem, and those who were building railways could put together interesting material on this subject. Many Canadians also served with the Royal Engineers in India, Mesopotamia, Persia and other countries, and every man must have had some engineering experiences differing from those of his fellows.

COURT ACTION FOLLOWS ELECTROLYSIS

ACCORDING to T. H. Hooper, waterworks superintendent, approximately twenty-five miles of Winnipeg's water mains are at present affected by stray electrical currents from the tracks of the Winnipeg Electric Railway Co. Mr. Hooper has been instructed to report upon the cost of examining the whole of the twenty-five miles affected. The city is now suing the company for $18,000 alleged damages through electrolysis.

SUIT AGAINST ONTARIO "HYDRO"

THE council of Stamford township, Ontario, is about to bring a test suit against the Hydro-Electric Power Commission of Ontario in connection with the power canal which is being built between Chippawa and Queenston. In the past five months sixty wells have dried up in Stamford within half a mile of the canal. The Hydro Commission decline to admit liability and refuse to supply the farmers affected with water unless they pay for it.

MOTOR FLUSHERS EFFECT BIG SAVINGS

INTERESTING facts relative to the saving effected by the replacement of horse-drawn equipment by motor street-flushers are given in the report of the Works Commissioner of Ottawa. He says: "Each of our flushers mounted on motor trucks has replaced ten horse-drawn outfits. Two 1,000-gallon power flushers mounted on 3½-ton trucks operated all year, flushing an average of 18 miles of pavement, of all widths per day at a cost of $1.72 per mile. The total cost was $4,650 for 150 days of actual operation. The teams formerly used accomplished this work for $16,800."

THE editorial, business and mechanical staffs of "The Canadian Engineer" wish every reader a right merry Christmas and a happy New Year.

PERSONALS

JOHN M. WILSON, who has just presented to the Hamilton Harbor Commission his report on the proposed waterfront development at that city, was born September 7th, 1883 in Toronto, and was educated in the Toronto public schools, at Harbord Collegiate and at S.P.S., University of Toronto, where he graduated in 1908 in civil engineering.

After a year with the Wood Products Co., which concern has since been absorbed by the Standard Chemical Co., Mr. Wilson joined the engineering staff of the water works department, city of Toronto, in 1909, but a few months later he resigned in order to become city engineer of Moose Jaw, Sask. In 1911 he left the employ of the city of Moose Jaw and formed the contracting firm of Wilson, Townsend & Saunders, whose head office was at Moose Jaw at first but who moved to Toronto in 1913. In 1914 Mr. Wilson withdrew from that firm in order to accept an appointment as senior assistant district engineer of the Toronto office of the Public Works Department of Canada, and a month later he was appointed district engineer of the central Ontario district, with headquarters at Toronto, which position he still retains. The central Ontario district includes the large territory which may be roughly described as being bound on the south by Lake Ontario, on the west by Georgian Bay, on the north by a line drawn from Manitoulin Island to North Bay, and on the east by a line drawn from North Bay to Kingston.

ALFRED NOSWORTHY, architect and industrial engineer, formerly of Lacroix & Nosworthy, Quebec, has opened an office in Montreal.

LIEUT. H. E. BATES, who returned recently from service overseas, has accepted a position with the Laurentide Co., Ltd., Grand'Mere, P.Q.

THOMAS R. PATTERSON, of Auburn, Ont., has been appointed engineer for Huron county succeeding his father, Donald Patterson, who resigned owing to ill-health.

MAJOR P. J. JENNINGS has returned from service in German East Africa, and is now in Calgary with the Department of the Interior, Reclamation Service, Irrigation Branch.

H. A. GOLDMAN, of Toronto, has been appointed acting secretary of the Toronto branch of the Engineering Institute of Canada, in place of W. S. Harvey, who resigned on account of moving to the United States.

PAUL F. SISE has been elected president of the Northern Electric Co., Ltd., succeeding Edward F. Sise, who has resigned in order to devote his time to other activities. Paul F Sise returned last spring from overseas.

SPENCER BALL, who graduated in civil engineering at the University of Saskatchewan, with the class of 1916, has been appointed to a position on the hydraulic engineering staff of the Hydro-Electric Power Commission of Ontario. Mr. Ball enlisted immediately upon graduation and within a couple of months was sent to France, where he won a commission as lieutenant and served with the Canadian forces until he was wounded not long before the armistice. He was confined to a military hospital in England for nearly a year, and reached Canada only a few weeks ago.

J. E. HOLLAMAN, who made the surveys and plans for the proposed development of Hamilton harbor, was born May 1st, 1887, in Glasgow, Scotland, and was educated in the public schools of that city, at Allen Glen high school and at the Glasgow and West of Scotland technical college, where he studied architecture. Simultaneously with his college course, Mr. Hollaman served a five-year apprenticeship in an architect's office in Glasgow. After graduation he went to the United States and worked in New York City for two years, obtaining general office experience and also six months' supervision of structural steel work. In 1909 he came to Canada and entered the employ of the works department of the city of Toronto. He assisted E. L. Cousins in the preparation of reports on pay-as-you-enter cars and other phases of street railway operation and in the making of surveys and plans for proposed subways, and in other miscellaneous engineering work. In 1912 he left the employ of the city to follow Mr. Cousins to the Toronto Harbor Commission, where he was employed at first as chief draftsman, and later as assistant on special works. He resigned from the staff of the Toronto Harbor Commission in 1918 to join the aviation department of the Imperial Munitions Board, where he carried out surveys and miscellaneous engineering work under the direction of J. B. Carswell. In December, 1918, he entered the employ of the Hamilton Harbor Commission to assist John M. Wilson in making a report on the proposed waterfront development, and since that date he has been in charge at Hamilton of the harbor commission's engineering office.

OBITUARIES

ALEXANDER ORR, of Orr Bros., contractors, Toronto, recently died, aged 57. Mr. Orr was born in Barrie, Ont., and had resided in Toronto for 35 years, during which time he had been engaged in contracting.

SIR JOHN JACKSON died last Monday in England, at the ago of 68. He was famous as a contractor for public works in various parts of the world, and was a civil engineer of note. Among the great projects with which he was connected were the Manchester Ship canal, the railway across the Andes, the barrage across the Euphrates river near Babylon, the Mesopotamia irrigation works, and harbor works in Canada, South Africa, Singapore and other countries.

JOHN H. ARMSTRONG, one of the oldest employees in the service of the Public Works Department of the Dominion government, died December 13th, in Midland, Ont., from neuritis after a week's illness. Mr. Armstrong was district engineer of the Midland district, which district extends as far north as Byng Inlet and includes Parry Sound, Muskoka and portions of the Georgian Bay and Lake Huron. Mr. Armstrong was in the Toronto office of the department for many years ,but upon the formation of the Midland district, he was appointed as engineer in charge of it. Mr. Armstrong is survived by a widow, two daughters and three sons.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

ADDITIONAL TENDERS PENDING

Not Including Those Reported in This Issue

BRIDGES, ROADS AND STREETS

Agassiz, B.C.—Movement is on foot for erection of bridge here.

Assiniboia, Man.—The erection of a temporary foot-bridge is contemplated. Clerk, Frank Ness, Kirkfield Park, Man.

Banff, Alta.—The bridge to be erected here over the Bow River, for which the Dominion government has called for tenders, will be built of reinforced concrete at an estimated cost of between $160,000 and $200,000. It is to be 416 feet long by 56 feet wide.

Beaverton, Ont.—Town council plans sidewalk and road repairs at cost of $5,000. By-law will be voted on. Clerk, G. A. Patterson.

Charleswood, Man.—Tenders addressed to A. B. Blakely, secretary-treasurer, Municipality of Charleswood, Man., will be received at the office of the Highway Commissioner, Winnipeg, Man., up to 12 o'clock noon on Tuesday, December 23rd, 1919, for the construction of concrete foundations, wooden Howe Truss spans and timber approaches thereto for a bridge over the Assiniboine River, near the village of Headingly, between the municipalities of Charleswood and Assiniboia. Plans and specifications may be obtained at the office of the Highway Commissioner, New Parliament Buildings, Winnipeg.

Charlottetown, P.E.I.—According to an announcement made by Hon. George E. Hughes, the government is planning to take advantage of the federal road grant and expect to expend $400,000 on roads next year.

Chatham, Ont.—By-law to raise $17,300 for the erection of a new steel bridge over McGregor's Creek at Princess St. will be submitted to ratepayers. City engineer, Mr. Adams.

Chatham, Ont.—Kent county council has recommended to the 1920 council the erection of a bridge across the River Thames at Prairie Siding. County road superintendent, L. A. Pardo, County Building, Chatham.

Chatham, Ont.—The farmers of Raleigh and Dover townships are urging the Kent county council to construct a bridge across the river a few miles below this city. County Road Supt., A. Pardo, County Bldg., Chatham.

Chatham, Ont.—City council passed a resolution, calling upon the Ontario government to proceed with the provincial highway scheme, and to designate the Longwoods Rd. as the route of the highway between Chatham and London.

Chilliwack, B.C.—Tenders will be called at once for construction of asphalt pavement at cost of $18,000. City clerk, Peter J. Brown.

Coquitlam, B.C.—Municipal council has put forward a proposition to the government that they rock the Clarke Rd. for a mile at an estimated cost of $6,200. Clerk, A. Haliburton.

Danville, Que.—Municipal corporations of St. Camille, Wottonville, Wotton and Shipton, Que., have decided to build a road between Marbleton and Danville under government specifications. Address, L. P. Bishop, Danville.

Headingly, Man.—If the project is approved by the municipalities interested, a $36,000 bridge will be built over the Assiniboine River at Headingly next summer. The structure will be of concrete and wood. By-laws will be submitted in Charleswood and Assiniboia to authorize the expenditure.

Kenora, Ont.—A by-law to borrow $25,000 for road improvements will be submitted to electors at municipal elections. Clerk, J. E. Currie.

Kent County, Ont.—County council recommended that the plans and specifications of the County Engineer for pavement at Wallaceburg, Ont., be accepted and be forwarded to the Department of Highways for approval. Plans and specifications of the Duffis Creek bridge will also be submitted to the department.

Levis, Que.—City council gave second reading to by-law to borrow $28,280 for paving of roads. Mayor, Mr. Belleau.

Mindemoya, Ont.—A definite good roads program on Manitoulin Island will be promoted as a result of a recent meeting held here, which was addressed by Hon. Beniah Bowman and an engineer from the Provincial Good Roads Department.

Morris, Man.—Engineers are here making plans and specifications for a bridge across the Red River. Approximate cost, $100,000. Provincial Highway Commissioner, A. McGillivray, Parliament Buildings, Winnipeg.

Ottawa, Ont.—The good roads policy initiated by the government this year in the form of an appropriation of $20,000,000, extending over a term of five years, is taking definite form and the spring and summer will see construction work actively in progress. The provinces will initiate and carry on the works, the Federal government approving the plans and contributing 40 per cent. of the cost. Ontario so far has filed plans for a provincial highway from Windsor to the Quebec boundary by way of Hamilton, Toronto, Kingston, Brockville and Prescott, with a branch road from Prescott to Ottawa. The plan of the Quebec government is to construct a first-class roadway from Hull to Montreal.

Port Hardy, B.C.—It is reported that the provincial government will construct a highway between Port Hardy and Coal Harbor next year. Minister of Public Works, Hon. J. H. King, Victoria.

Quebec, Que.—The Quebec Board of Trade and that of Drummondville are communicating with the officials of a number of cities and towns along the south shore of the St.

Lawrence River to advocate a highway that would lead from Montreal to Quebec on the south shore. The promoters of the idea have organized a monster delegation from every city, town, village and parish along the proposed highway, and this will meet the Provincial Cabinet, requesting the construction of the new road without delay. The idea is to start work early next spring.

Sarnia, Ont.—Lambton county council will purchase stone-crushers and other road machinery.

Sarnia, Ont.—A by-law to raise $35,000 for the purchase of an asphalt plant and equipment will be submitted to the ratepayers at the municipal elections. City clerk, J. D. Stewart.

Simcoe, Ont.—Norfolk county council contemplates purchasing more road machinery. County road superintendent, G. R. Marston, Simcoe.

St. Clements, Man.—Tenders will be received by Thos. Bunn, secretary-treasurer, up to noon on Tuesday, December 23rd, 1919, for the supply and delivery of approximately 6,200 cubic yards of gravel. For specifications, apply to W. G. Mawhinney, Municipal Engineer, Municipal Hall, East Selkirk, Man., or to A. McGillivray, Highway Commissioner, Winnipeg.

St. John, N.B.—City council will have plans and specifications prepared for paving the North and South sides of Haymarket Square with granite blocks on a cement concrete foundation. City engineer, G. N. Hatfield.

St. Polycarpe, Que.—Municipality plans construction of 11,043 ft. of gravel roads; also macadam road, estimated to cost $25,000. Secretary-treasurer, J. R. Ouimet.

Three Rivers, Que.—Council plans construction of pavement at cost of $100,000. Engineer, Z. St. Lambert.

Toronto, Ont.—Board of Works decided to have Davenport Rd. paved and otherwise improved at a cost of about $289,550.

Toronto, Ont.—Works Committee requested Commissioner of Works Harris to bring in a report recommending the grading of Woodbine Ave., between Kingston Rd. and Gerrard St.

Toronto, Ont.—The Board of Works, subject to a report by Commissioners Harris and Forman, decided to extend Norway Ave. through to Lee Ave. The cost, exclusive of grading, will be about $40,000.

Vancouver, B.C.—The Woodward Departmental Stores plan erection of an overhead bridge over the alley between Hastings and Cordova Sts.

Victoria, B.C.—The Provincial Department of Public Works has under consideration the construction of a road from Campbell River to Salmon River, in Sayward district. Minister of Public Works, Hon. J. H. King.

Winnipeg, Man.—Permission has been granted by the city council for the erection of a footbridge from Donald St. to Portage Ave. City clerk, C. J. Brown.

Winnipeg, Man.—City Engineer W. P. Brereton will report on the cost of lengthening the approach to the Arlington St. bridge and on draining the McPhillips St. subway.

Winnipeg, Man.—Manitoba province, in conjunction with the municipalities, is planning the construction next year of several large bridges at an approximate cost of several hundred thousand dollars.

Winnipeg, Man.—A. McGillivray, Provincial Highway Commissioner, has announced that plans have been completed by municipalities of the province of Manitoba for the issue of debentures for an expenditure of over $5,700,000 on road-building.

Winnipeg, Man.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Friday, December 19th, 1919, for the construction of roads and sidewalks at Tuxedo Military Hospital, Winnipeg. Plans and specifications may be seen at the offices of the Chief Architect, Department of Public Works, Ottawa; the Superintendent of Military Hospitals, Notre Dame Investment Building, Winnipeg, and the Resident Architect, Lindsay Building, Winnipeg, Man.

Wroxeter, Ont.—Town council plans construction of cement walks at cost of $5,000. By-law will be voted on. Clerk, D. M. MacTavish.

York Tp., Ont.—The township solicitor was instructed by the council to proceed with the expropriation of land for the extension of Woodville Ave.

WATER, SEWAGE AND REFUSE

Dresden, Ont.—A by-law will be voted on at the municipal elections to provide $10,000 for a water tank and equipment for a waterworks system. Clerk, J. T. Bridgewater.

Guelph, Ont.—Plans for the construction of a sewage disposal plant to serve Guelph township have been approved by the Provincial Board of Health. City engineer, F. McArthur.

Hamilton, Ont.—Board of Control recommended construction of 2-inch water main to the Isolation Hospital at a cost of $3,500. City engineer, E. R. Gray.

Hamilton, Ont.—City council intends to construct a 4-inch force sewer, well and pumping plant on Simcoe St., at an estimated cost of $3,865.34. City clerk, S. H. Kent,

Hamilton, Ont.—Board of Control accepted the tenders of City Engineer E. R. Gray for installation of sewers on Bay and Stinson Sts. and Roxbury Ave. amounting to about $2,000.

Kincardine, Ont.—By-law will be submitted to ratepayers at next municipal election to borrow $9,000 for extensions to waterworks system. Clerk, John H. Scougall.

Nanaimo, B.C.—Two schemes for the extension of the waterworks system are under consideration by the city council. The first one is estimated to cost $166,051, and the second, $199,107. Mayor, H. McKenzie.

Newmarket, Ont.—Town council intends to construct sewers on several streets at an estimated cost of $18,000. Clerk, P. J. Anderson.

Orillia, Ont.—Town council has issued debentures to the amount of $24,000 for waterworks. Clerk, C. E. Grant.

Petrolia, Ont.—Town council plans construction of glazed tile sewer. Clerk, John McHattie.

Port Dalhousie, Ont.—Town council plans waterworks system. Clerk, J. M. A. Waugh.

Sandwich and Ojibway, Ont.—No award was made by Essex Border Utilities Commission for completion of south sewage interceptor, for which tenders closed November 27th. Commissioner may consider cost-plus basis.

St. Louis de Gonzague, Que.—Dominion Department of Public Works let contract to O. Poliquin, Portneuf, Que., for two concrete abutments.

St. Thomas, Ont.—Tenders will be received by W. C. Miller, city engineer, until noon, Tuesday, December 30th, 1919, for the installation of electric and gasoline auxiliary pumping equipment for the waterworks. Plans and specifications may be obtained at the city engineer's office.

Three Rivers, Que.—Council plans aqueduct improvements at cost of $20,000. Clerk, A. Nobert.

Three Rivers, Que.—Council plans construction of sewers at cost of $75,000. Engineer, Z. St. Lambert.

Toronto, Ont.—Tenders addressed to T. L. Church (mayor), chairman, Board of Control, City Hall, will be received up to 12 o'clock noon on Tuesday, February 10th, 1920, for the supply and installation of: Tender No. 36—One or more 16 to 20 million Imperial gallon centrifugal pumps at the waterworks main pumping station. Specifications may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—The Oakoal Co. has offered to buy the city garbage for $15,000 per year At the present time it costs the city $172,000 to dispose of it. The company proposes to erect a plant for the manufacture of briquettes

Driveways of old macadam in Mount Pleasant Cemetery, Toronto, Ont., resurfaced with "Tarvia-X".

Ten Years of Road Satisfaction—

THESE two driveways in Mount Pleasant Cemetery, Toronto, Ontario, are convincing evidence of the excellence and durability of Tarvia as a road-making and preserving material.

The lower of these two roads was given a 3-inch resurfacing with "Tarvia-X" in 1909. The upper road was resurfaced in the same way in 1910. The above photographs were taken in 1918. The condition of these driveways today after many years of service, speaks for itself.

Tarvia Helps Canadian Road Engineers

Canadian road engineers have severe conditions to face. Canadian roads must not only be strong enough to stand up under the wear of traffic, but they must also be waterproof and frost-proof or they will not come through the severe winters and the spring thaws without going to pieces.

At the same time the expense of the roads must not be out of proportion to adjoining property values.

No material meets all these conditions so satisfactorily as Tarvia. It is a coal-tar preparation made in several grades, suitable for new road construction, reconstruction, surface treating or patching.

Tarvia is easily applied; it prevents dust and mud; it stands up well under motor traffic; and its cost is low.

Booklets free on request.

Tarvia

Preserves Roads-Prevents Dust

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by anyone interested.

If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention.

MONTREAL TORONTO
WINNIPEG VANCOUVE

The Barrett Company LIMITED

ST. JOHN, N.B. HALIFAX, N.S.
SYDNEY, N.S.

from the garbage. The Works Commissioner will report on the matter.

Windsor, Ont.—If the plan of the Essex Border Utility Commission to consolidate the waterworks systems of the border municipalities by taking over the Windsor and Walkerville plants is placed before the taxpayers of Windsor at the municipal elections in January, the Windsor Water Board will ask the city council to submit a by-law authorizing the expenditure of $350,000 to construct a filtration system as an addition to the present plant.

LIGHT, HEAT AND POWER

Alliston, Ont.—Council has issued debentures to the amount of $8,000 for Hydro-Electric extensions. Clerk, J. E. Addis.

Almonte, Ont.—A by-law regarding the acquisition of the Wylie power plant will be submitted to the electors. The sum mentioned is $25,000, of which $20,000 is for the actual cost of purchase and the balance for development.

Crediton, Ont.—Estimates will be prepared and by-law submitted shortly for Hydro system, street lighting, etc. Engineer, Mr. Doerr, superintendent of Hydro at Exeter, Ont.

Fort Metachewan, Ont.—British Syndicate plans construction of power development plant to cost $250,000. Engineers, Sutcliffe and Neelands, New Liskeard, Ont.

Halifax, N.S.—Tenders, addressed to E. H. Armstrong, Commissioner of Public Works and Mines, Halifax, N.S., will be received until 1 o'clock p.m., on Wednesday, December 24th, 1919, for supply of material and erection of a transformer house on the grounds of the Nova Scotia Technical College at Halifax, according to plans and specifications which may be seen at the office of the Department of Public Works and Mines, Halifax, N.S. E. H. Armstrong, Commissioner of Public Works and Mines.

Halifax, N.S.—The Nova Scotia Power Commission has been authorized to proceed with the development of the water powers at St. Margaret's Bay, and will undertake and carry out as rapidly as possible an initial development capable of supplying in Halifax 7,800 h.p. The initial expenditure is roughly estimated at $1,000,000, and the expansion of the plant to its greatest capacity, which will be carried out as the demand for power increases, will cost approximately $200,000 more. Chief Engineer of Commission, H. K. Smith.

Iroquois Falls, Ont.—The Abitibi Power & Paper Co., which now develops 20,000 h.p. here and owns a model townsite with population of 2,500, is planning large extensions. The company is now turning out 300 tons of paper a day, and it is said that they will more than double their output and spend about $3,000,000 on additional mills, power development, etc. It is rumored that a contract has already been let to Morrow & Beatty, Ltd., of Peterboro, Ont., who were the contractors for the initial hydro-electric installation, for extensions to the power development costing between $1,000,000 and $1,500,000.

London, Ont.—General Manager Buchanan, of the Public Utilities Commission, stated recently that the commission stands ready to build a supplementary electric power plant the moment the city begins a new dam across the river. It is believed the dam could be erected for about $150,000, and it would cost another $100,000 to install the power generating plant.

Newberry, Ont.—Village council plans Hydro system. By-law will be submitted in January. Reeve, Mr. Holman.

Toronto, Ont.—Board of Control sent on a recommendation to the city council approving the application to the Railway Board for power to issue debentures to the amount of $950,000 for extensions to the Hydro-Electric system in this city.

Vancouver, B.C.—British Columbia Electric Ry. Co. plans extensions to gas plant at cost of $150,000.

Windsor, Ont.—A by-law to take over and place under the direction of the Hydro Commission the lighting plant of the S.W. and A. Ry. at a cost of $190,000 will be submitted to ratepayers at civic elections.

RAILWAYS

Guelph, Ont.—City council decided to submit to the ratepayers the by-law respecting the sale of the Guelph Radial Ry. to the Hydro-Electric Power Commission of Ontario for $150,000.

Oshawa, Ont.—Oshawa Railway Co. proposes to lay additional trackage.

Quebec, Que.—The building of a new railroad into the Temiskaming region and the expenditure of five million dollars to help develop new rural communities was announced last week by Sir Charles Fitzpatrick, Lieutenant-Governor of Quebec.

Quebec, Que.—The farmers of Lake Saint John district have formed a company, to be known as the "Farmers' Railroad Company of Normandin Township," and plan the construction and operation of a railroad several hundred miles in length. The company will apply for a provincial charter at the coming session of the legislature.

Quebec, Que.—Roberval and Saguenay Railroad will apply to legislature for power to construct steam or electric line. Solicitors, Lapointe and Rochette, 42 St. Pierre St., Quebec.

Toronto, Ont.—Tenders have been called for the construction of the Mount Pleasant car line.

Welland, Ont.—According to a letter received by W. M. German, Industrial Commissioner for this city, from E. D. Cahill, general solicitor of the T., H. and Buffalo Ry. at Hamilton, neither the C.P.R. nor the T., H. and B. contemplate the construction of another railway line to the Niagara River through this county, as has been recently reported. It is thought, however, that such a new line to the frontier is contemplated, but that it will run from St. Catharines to the border north of this county in competition with the Grand Trunk line. Reports state that a new international bridge to New York State is to be built over the Niagara River by the C.P.R. or the T., H. and B., or probably by both lines in conjunction.

Winnipeg, Man.—Premier Norris, of Manitoba, recently stated that if the Federal government refuse to build a railway line into the Copper Lake gold district, the provincial government will act in the matter.

York Tp., Ont.—Township council decided to call for a vote on the Toronto and Eastern Radial bond guarantee about the middle of January.

FACTORIES AND LARGE BUILDINGS

Acton, Ont.—Toronto Suburban Railway Co. plans erection of freight sheds. General manager, W. Radford, 2896 Dundas St. West, Toronto.

Barton Tp., Ont.—Township council has given first and second readings to a by-law for the erection of a memorial community hall. Estimated cost, $35,000.

Barton Tp., Ont.—Township council authorized the rebuilding of the Homeside fire hall, destroyed by recent storm. Clerk, A. G. E. Bryant, Mount Hamilton, Ont.

Belleville, Ont.—Board of directors of Albert College plan erection of new buildings on 50-acre site given by city. Principal, Dr. Baker.

Brantford, Ont.—Steel contract in connection with erection of $75,000 factory for Barber-Ellis, Ltd., Toronto, let to Burlington Steel Co., Hamilton, and roofing contract to Carmichael Waterproofing Co., Toronto.

BURLINGTON
STEEL CO LTD
HAMILTON
BARS BENT TO SHAPE

STEEL BARS
FOR CONCRETE REINFORCEMENT
ROUNDS, SQUARES, TWISTED SQUARES,
FLATS, ANGLES.

Brantford, Ont.—The Brantford Cordage Co. will replace their brick warehouse, recently destroyed by storm, with a steel and brick structure, and P. H. Secord and Sons Construction Co. has commenced the work.

Brownsburg, Que.—Douglas Bremner Co., 10 Cathcart St., Montreal, have general contract and masonry and will let sub-contracts and buy material for three factory buildings costing $50,000 for Dominion Cartridge Co.; head office, 120 St James St., Montreal.

Campbellton, N.B.—Contract let to J. and A. Harquail for erection of $50,000 school.

Cobourg, Ont.—A Rochester firm of furniture manufacturers contemplate locating a plant here and are asking for a $50,000 loan from the town. Address, A. L. Jex, Cobourg.

East St. John, N.B.—Town council plans erection of school. Secretary, Gordon Flewelling.

Fredericton Junction, N.B.—The C.P.R. is planning to erect a $50,000 station here.

Fredericton, N.B.—Contract for improvements to the Y.M.C.A. building let to Joseph Timms.

Galt, Ont.—South Waterloo Trades and Labor Council has under consideration the erection of a Labor Temple in this city at a cost of $50,000 or $60,000.

Glace Bay, N.S.—Y.M.C.A. have secured a site for erection of building.

Guelph, Ont.—A movement is on foot for extension of Winter Fair building. Address, Ald. Burgess.

Haileybury, Ont.—Business block destroyed by fire with loss of $40,000. Owner, F. Askar.

Halifax, N.S.—The Maritime Telegraph and Telephone Co. will introduce into this city the improved automatic telephone system, and in preparation for this have awarded contract to Rhodes, Curry and Co. for the erection of a new building to cost approximately $400,000.

Hamilton, Ont.—Contract let to Canadian Engineering and Construction Co., Bank of Hamilton Building, for foundation work for factory of Firestone Tire and Rubber Co.

Hamilton, Ont.—Firth Bros., of this city, will erect a factory at the corner of Cannon and Hughson Sts.

Hamilton, Ont.—A large new theatre will be erected on King William St., between Mary and Katharine Sts.

Hamilton, Ont.—Tallman Brass Co., Burlington St., will extend its plant.

Hamilton, Ont.—Extensive alterations to Grand Theatre are planned by A. J. Small, 11 Adelaide St. West, Toronto.

Hamilton, Ont.—General contract, masonry and carpentry let to Frid Construction Co., Clyde Building, for factory costing $75,000 for Norton Co., Worcester, Mass. Hamilton Bridge Co. have structural steel contract.

Hespeler, Ont.—Town council plans erection of school addition. Clerk, M. E. Jardine.

Heward, Sask.—The Great War Veterans' Association are considering the erection of a memorial hospital.

Humboldt, Sask.—The Benedictine Fathers plan construction of a college.

Ingersoll, Ont.—Tenders for erection of Separate School will be called by Father Gnam. Estimated cost, $20,000.

Kingston, Ont.—Tenders will be called for erection of two bathing-houses. Clerk, W. W. Sands, M.D.

Kitchener, Ont.—Tenders will be received up to December 31st by T. A. Witzel, 399 King St. East, for all trades for erection of $15,000 factory addition.

London, Ont.—Members of Cronyn Memorial Church are considering the erection of a new parish hall.

Loreburn, Sask.—Contract let to J. W. Osborne by municipal council for erection of hall at cost of $12,000.

Montreal, Que.—Contract let to J. Marcotte for erection of warehouse for British American Oil Co. Estimated cost, $8,000.

Montreal, Que.—A permit has been taken out in the name of M. A. Mercure, 419 Labrecque St., for the reconstruction of Laval University. The amount mentioned is $40,000.

New Waterford, N.S.—Town plans erection of hospital to cost $80,000. Clerk, J. McKinnon.

New Westminster, B.C.—Hyslop Hardware Co. will erect a storage building on Gilley St.

New Westminster, B.C.—Electors will vote on by-law in January providing for erection of $60,000 cold storage plant. Mayor, R. W. Gray.

Niagara Falls, Ont.—Fire completely gutted the local car barn of the Niagara, St. Catharines and Toronto Street Ry. recently. Loss, $40,000.

Orono, Ont.—C. J. Thornton proposes to erect a sawmill. Electric power will be utilized.

Ottawa, Ont.—Tenders will shortly be called by P. Levesque, architect, 115 St. John St., Quebec, Que., for erection of bank for La Banque Nationale. Estimated cost, $80,000.

Owen Sound, Ont.—A by-law to supply funds for the erection and equipment of a technical school and necessary additions to the Collegiate Institute at an approximate cost of $180,000 will be submitted to the electors in January.

Peace River, Alta.—The Garke Elevator Co. plans erection of an elevator.

Perdue, Sask.—F. O. Taylor has general contract for school costing $19,000 for Perdue School District.

Peterboro', Ont.—By-law granting a free site and fixed assessment to the Canadian Aladdin Co., Ltd., a branch of the present company in Bay City, Mich., will be submitted to the ratepayers. The company proposes to erect a plant.

Point Grey, B.C.—Royal Financial Corporation proposes to erect six storehouses.

Point Grey, B.C.—Coast Box Co. proposes to erect a $12,000 factory.

Quebec, Que.—The Quebec Glove and Leather Co. is making an addition to its premises on 3rd Ave. This addition will be a three-story structure, and will cost approximately $1,200.

Quebec, Que.—Repairs to the extent of $35,000 are to be made to the Boswell Brewery plant on St. Valier St.

Regina, Sask.—Plans for additions to Collegiate Institute are under consideration by Collegiate Board. Address, W. G. Styles.

Regina, Sask.—Premier Martin has announced that the Department of Education will build nine more public schools in the spring in the Mennonite districts of the province.

Regina, Sask.—Regina Oakoal Co. plans to establish a plant, at a cost of between $35,000 and $40,000, for the conversion of garbage into fuel.

Sandwich, Ont.—Assumption College plans erection of college building. President, Rev. F. Foster.

Sandwich East, Ont.—Fire totally destroyed Lakeview Hotel. Owner, Frederick J. Kirsch. Loss, $20,000.

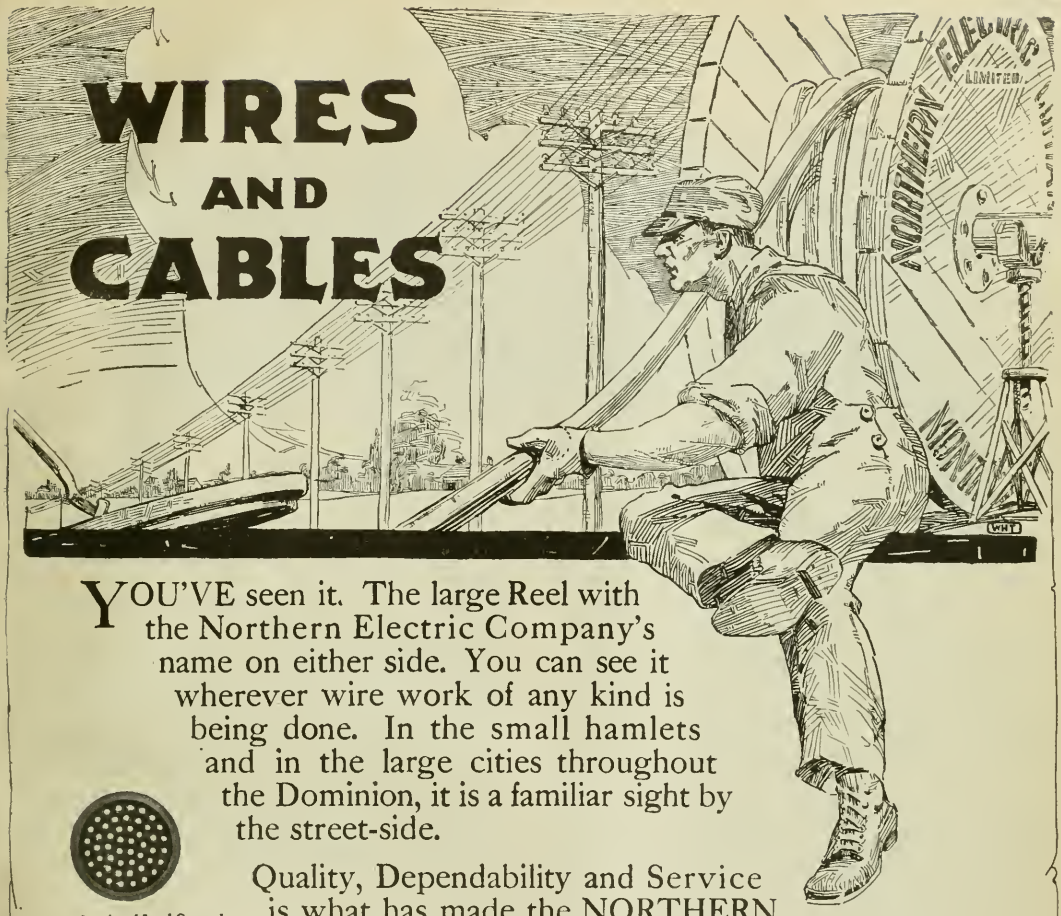
Sarnia, Ont.—According to an announcement made by S. A. Howard, a Detroit banker, plans are well under way by the Lake Huron River Steel Corporation to build a $15,000,000 steel plant along the River St. Clair, work to start on March 1st. Among those associated with Mr. Howard are J. J. Mahon, of the Imperial Munition Board of Canada, and a number of other prominent Canadian and American steel magnates.

Sarnia, Ont.—By-law will be submitted to ratepayers at municipal elections to grant $75,000 to the Sarnia General Hospital for erection of new buildings. City clerk, J. D. Stewart.

Sarnia, Ont.—The Sarnia Chamber of Commerce has secured an option on the Northern Hotel, which, it is stated, it will turn into a Chamber of Commerce building and modern apartment house.

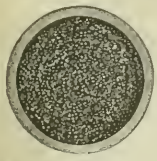
Three Rivers, Que.—City plans erection of civic hospital to cost $50,000. Clerk, Art. Nobert.

WIRES AND CABLES



YOU'VE seen it. The large Reel with the Northern Electric Company's name on either side. You can see it wherever wire work of any kind is being done. In the small hamlets and in the large cities throughout the Dominion, it is a familiar sight by the street-side.

Paper Insulated Lead Covered Telegraph Cable



Paper Insulated Lead Covered Telephone Cable

Paper Insulated Lead Covered Power Cable

Quality, Dependability and Service is what has made the NORTHERN ELECTRIC COMPANY LIMITED the largest manufacturers of bare and insulated Wire and Cable.

Our Nearest House will be glad to furnish specifications and prices on any type of bare or insulated wire and cable for electrical purposes—write us to-day.

Three Rivers, Que.—Arsenault and Ahern, 44 St. Pierre St., have general contract, and Germain and Freres, 87 St. Antoine St., have plumbing for Roman Catholic school, costing $200,000.

Toronto, Ont.—York county council plans erection of registry office.

Toronto, Ont.—University of Toronto plans erection of women's building. Superintendent, Graham Bell, University of Toronto.

Toronto, Ont.—Total cost of erection of club building planned by Beaches G.W.V.A. is $200,000. Member of committee, Alfred Scadding.

Toronto, Ont.—Fire Chief Russell has selected a site for a new fire station in Ashbridge's Bay district at Commissioner and Munition Sts.

Toronto, Ont.—Permit granted to Robert Gray for one-story metal-clad machine shop, north side of Geary Ave., near Dufferin, at cost of $1,000.

Toronto, Ont.—Work has started on the construction of a large addition to G. E. Gooderham and Co.'s motor car showrooms and garage on Sheppard St.

Toronto, Ont.—Permit issued to the Wm. Davies Co. for erection of a store at 29-31 Queen St. West. The new building is now being erected. It will cost $60,000.

Toronto, Ont.—A three-story brick and concrete building is being erected at 105-7-9 West Richmond St. for the Rapid Electrotype Co., and will be ready about January 1st.

Toronto, Ont.—A moving-picture theatre to cost in the neighborhood of $50,000 is to be constructed on Danforth Ave., near Bathgate. Excavations are at present under way.

Toronto, Ont.—Brouse, Mitchell and Co., 71 Bay St., have purchased the four-story brick building at 75 Bay St., and alterations costing about $15,000 will be made early in the new year.

Toronto, Ont.—Canadian Allis-Chalmers, Ltd., 212 King St. West, Toronto, have steel contract for plate mill costing $200,000 for Baldwins, Ltd., Swansea, Wales. Superintendent, Mr. Cowan, Ashbridge's Bay, Toronto.

Toronto, Ont.—Permit issued to G. Hesk for one-story brick public storage garage, 2189 Queen St. East, at cost of $8,500, and to Misses L. and E. Colvin for three-story addition to Assembly Hall, 1691-1693 Dundas St. West, near Mavety St., at cost of $6,800.

Toronto, Ont.—Plans are being prepared for a $200,000 home for the nurses of St. Michael's Hospital. The building will be of reinforced concrete, six stories and a basement, and construction will be started in the spring. Architects, Hynes, Feldman and Watson, McKinnon Building.

Toronto, Ont.—The Aero Club of Canada have received a proposition from a municipality in Canada, the name of which they will not divulge, for the setting aside of approximately one thousand acres for an aerodrome site. As soon as the scheme is completed the Aero Club state that public announcements will be made.

Toronto, Ont.—Three new factories will be erected near the corner of Dupont St. and Manning Ave. The north-east corner has been sold to the Willard Chocolate Co., who will build an ice cream factory at a cost of $140,000. On the north-west corner the Ward Baking Co., of New York, will erect a large bakery, and on the 150-foot site on the north side of Dupont St. the Kinnear Wholesale Grocery Co. will build a $150,000 warehouse. The construction of the factories is expected to begin in a few months.

Vancouver, B.C.—Edward B. Welch has taken out a permit for the erection of a service garage at 660 Howe St. at a cost of $24,000.

Vancouver, B.C.—The Schaake Machinery Co. has taken out a permit to build a 40-ft. addition to their factory on Industrial Island, which is to be used as a machine shop. It will cost $5,000.

Vancouver, B.C.—The Canada Western Woollen Mills have taken out a permit for a $4,000 warehouse at 440 Clark Drive. The Gordon Drysdale Co. have also taken out a permit for $4,000 to build an addition to the rear of their premises on Granville St.

Vancouver, B.C.—David Spencer, Ltd., plan large addition to their premises. Approximate cost, $1,000,000.

Verdun, Que.—General contract, masonry, excavations and foundations in connection with $100,000 school addition let to Archambault and Leclair, Montreal, by Protestant School Commission; plumbing and heating contract let to Thos. O'Connell, 183 Ottawa St., Montreal, at $16,800.

Victoria, B.C.—The lumber mill of Moore and Whittington was gutted by fire recently. Estimated loss, $90,000.

Victoria, B.C.—City council is considering salt water swimming bath scheme at a total cost of $45,000, including $30,000 for erection of building. Architect, J. C. M. Keith.

Walkerton, Ont.—Children's Aid Society plans erection of new building in Bruce county next spring. Treasurer, Mr. Burrows.

Welland, Ont.—S. L. Lambert plans erection of theatre.

Westboro, Ont.—A new church, to take the place of All Saints' Church, will be erected here next year. Rector, Rev. (Col.) R. H. Steacy.

Windsor, Ont.—Property at the corner of Ouellette Ave. and Park St. has been purchased by the directors of the Border Cities Hotel Co. for the erection of the proposed million dollar hotel, upon which work of construction will be started about February 15th.

Windsor, Ont.—Tenders on all trades in connection with erection of theatre will be received by J. and J. J. Allen, Richmond and Victoria Sts., Toronto, up to January 1st. Plans with owners and with Howard Smith, 6 Victoria Block, Windsor.

Winnipeg, Man.—The board of governors of the University of Manitoba decided to lay the matter of the erection of a permanent university for the province before the government, along with the plans and estimated cost.

Winnipeg, Man.—The erection of a manufacturing plant here to take care of small industries is under consideration by the Industrial Development Bureau of the Board of Trade.

Winnipeg, Man.—Carter, Halls, Aldinger Co. have general contract for branch bank for Merchants' Bank of Canada. Architects, J. D. Atchison and Co., 914 Boyd Building.

Wynyard, Sask.—Town council plans erection of municipal hospital at cost of $30,000. Clerk, T. B. Baker.

MISCELLANEOUS

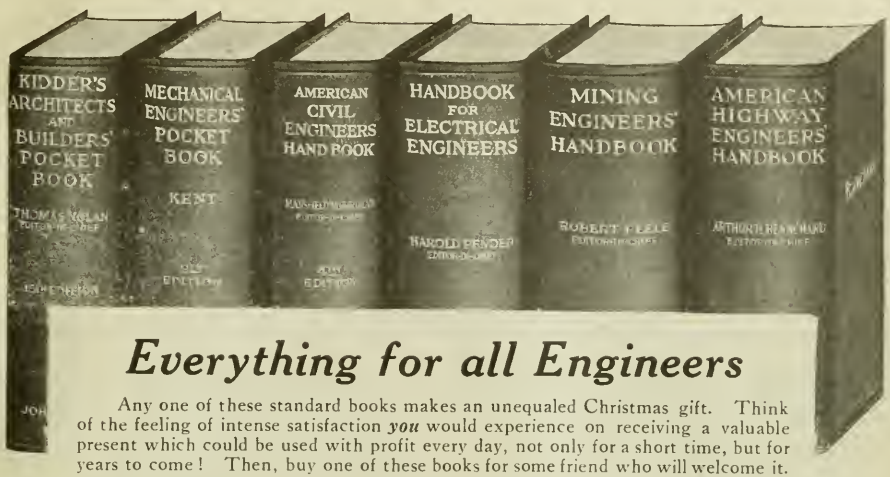
Brantford, Ont.—By-laws to be submitted to the electors in January include the following: New Lorne bridge, $211,000; purchase of new motor fire truck, $10,800.

Chatham, Ont.—By-law to raise $10,000 for the establishment of an athletic park will be submitted to ratepayers.

New Westminster, B.C.—Tenders, addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Wednesday, January 7th, 1920, for the construction of a dam, embankment and three groynes at Nicoamen Island, Fraser River, District of New Westminster, B.C. Plans may be seen and specification obtained at the Department of Public Works, Ottawa; at the offices of the District Engineers at Victoria, B.C.; New Westminster, B.C., and at the Post Offices, Vancouver, B.C., and Deroche, B.C.

Ottawa, Ont.—The following are among the companies recently incorporated: The Dominion Engineering and Machinery Co., Ltd., with a capital stock of $3,000,000, and head offices at Montreal; Super-Cement (America) Co., Ltd., Toronto, $500,000; Scientific Experimenter, Ltd., Montreal, $100,000.

Ottawa, Ont.—City council awarded contract for 5,000 pounds of lead pipe to McKinley and Northwood, and for five tons of pig lead to the Canada Metal Co.



Everything for all Engineers

Any one of these standard books makes an unequaled Christmas gift. Think of the feeling of intense satisfaction *you* would experience on receiving a valuable present which could be used with profit every day, not only for a short time, but for years to come! Then, buy one of these books for some friend who will welcome it.

A Brand New Edition!

American Civil Engineers' Handbook

4th Edition, Extensively Revised and Enlarged. MANSFIELD MERRIMAN, Editor-in-Chief, and 18 Associate Editors.

The pre-eminent Handbook for civil engineers. In addition to two new sections on important subjects (Electric Railroads, and Irrigation and Drainage), the others have been revised—in some cases practically rewritten—and brought up to date. Now, more than ever before, this is the standard book for the practicing civil engineer.

1959 pages. 4¾ by 7. Fully illustrated. Flexible binding, $6.00 net. (Ready February 20, 1920.)

American Highway Engineers' Handbook

ARTHUR H. BLANCHARD, Editor-in-Chief, and 17 Associate Editors.

"So complete in the broad and comprehensive way in which it discusses all questions relating to modern highway matters that it should prove a valuable reference book to any of those engaged in this line of work," said one reviewer. He's right, it is.

xxv+1658 pages. 4¾ by 7. Illustrated. Flexible binding, $6.00 net.

Handbook for Electrical Engineers

HAROLD PENDER, Editor-in-Chief, and a Staff of Specialists.

A Handbook of electrical facts covering every field of electrical engineering, and offering data which would ordinarily be accessible only through an extensive reference library.

xxviii+2023 pages. 4¾ by 7. Illustrated. Flexible binding, $6.00 net.

Kidder's Architects' and Builders' Pocket Book

16th Edition, Revised and Enlarged. THOMAS NOLAN, Editor-in-Chief, and a Staff of Specialists.

Contains in condensed form the knowledge and experience of a score of experts in every phase of building design and construction.

xxiii+1816 pages. 4¾ by 7. Illustrated. Flexible binding, $6.00 net.

Mechanical Engineers' Pocket Book

9th Edition, Revised. By the late WILLIAM KENT, D.Sc., with the Assistance of ROBERT THURSTON KENT, M.E.

Covers the entire field of mechanical engineering, presenting the information that the engineer needs in his daily work, in condensed, usable form.

xlvi+1526 pages. 4¾ by 7. Illustrated. Flexible binding $6.00 net.

Mining Engineers' Handbook

ROBERT PEELE, Editor-in-Chief, and 43 Associate Editors.

For mining engineers generally, and also for those whose interest is in the construction details involved in the installation of plant.

x+2375 pages. 4¾ by 7. 2000 figures. Flexible binding $6.00 net.

Peterboro', Ont.—By-law to purchase Riverside Park and adjoining properties as a public park and athletic grounds will be submitted to the ratepayers at the January elections.

South Slocan, B.C.—Dennis Sullivan, of Vallican, B.C., has received the contract for the furnishing of 1,050 poles for the Dominion government telephone line from South Slocan to Slocan City.

St. Catharines, Ont.—The city council will ask the Dominion government to turn over to the Victoria Park Commission the lands of the Welland Canal, now out of use for navigation purposes, to be transformed into a provincial park reservation.

St. Lambert, Que.—The town has taken over from private companies the operation of its water, light and power services.

St. Thomas, Ont.—City plans re erection of grand stand, recently destroyed by storm. Steel or concrete construction. Clerk, W. B. Doherty.

Toronto, Ont.—The Harbor Commission have agreed to develop the waterfront from Woodbine Ave. to the city limits if the city will purchase the lots. The development will be on the lines of the Humber improvements.

Toronto, Ont.—Tenders will be received up to and including January 15th, 1920, for the manufacture, crating and delivery of two thousand five hundred survey posts made of 1-in. wrought iron pipe, each 30 ins. long, bronze cap, welded foot plate and cement filled. Plans and specifications may be seen at the office of L. V. Rorke, director of surveys.

Vancouver, B.C.—According to A. D. Swan, consulting engineer of Montreal, Que., who has been appointed in connection with the work, the Dominion government has authorized the construction, at a cost of $5,000,000, of the first unit of the Vancouver harbor works. Tenders will be called for within the next six or eight weeks.

White Point, N.S.—Contract let by Dominion Department of Public Works to A. W. Girroir and W. F. McKinnon, Antigonish, N.S., for breakwater extension.

Tenders Called For

TENDERS FOR PUMPING EQUIPMENT

CITY OF ST. THOMAS, ONTARIO

Tenders will be received by the undersigned until noon, Tuesday, December 30th, 1919, for the installation of Electric and Gasoline Auxiliary Pumping Equipment for the St. Thomas Waterworks. Bidders may tender on either Electric or Gasoline Equipment, or both.

Plans and specifications may be obtained at this office. Lowest or any tender not necessarily accepted.

W. C. MILLER, City Engineer.

December 11th, 1919. 392

TENDERS FOR PUMPS

Tenders will be received by registered post only, addressed to the Chairman, Board of Control, City Hall, Toronto, up to 12 o'clock noon on Tuesday, February 10th, 1920, for the supply and installation of:—

Tender No. 36—One or more 16 to 20 Million Imperial Gallon Centrifugal Pumps at the Waterworks Main Pumping Station.

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. Tenders must comply strictly with conditions of City By-law as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH (Mayor),

390 Chairman, Board of Control.

Steam Turbine Driven Turbo-Blower Set

With Condensing Plant. For quick delivery from stock at very favorable price.

FURTHER PARTICULARS FROM

ESCHER, WYSS & CO.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Mining Methods and Tunnelling at the Front

Underground Adventures with Second Canadian Tunnelling Company—Defense of Mount Sorrel—Construction of Galleries and Dugouts—Surveying Under Difficulties—Experiences at Listening Posts—Light Charges in Bore Holes Rout Enemy Listeners

By CAPT. JAS. A. KNIGHT, M.C.

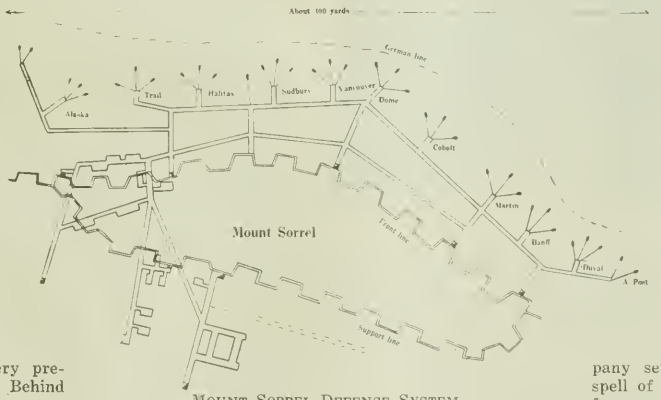
Formerly with the Second Canadian Tunnelling Company

THE Second Canadian Tunnelling Company arrived in France in March, 1916, all the personnel being drawn from the Canadian mining camps. My personal knowledge of the company dates from July 1st, 1916, when I joined it on transfer from the cyclists. On June 2nd, 1916, when the Germans launched an attack on Sanctuary Wood, this company was mining in the front line and had about 50% of its personnel rendered casualties. It was then withdrawn and reorganized, and several of us were taken on as probationers for commission, as the supply of mining officers was very low. I was first given one stripe and a gang of fourteen men, working at the reclaiming of some old saps which had been captured by Heinie and later retaken by our Second Division. As soon as we had living quarters arranged, we commenced to drive towards the German line, as we wanted to get a protecting gallery around the high ground known as Mount Sorrel, about 1½ miles south-east of Ypres and only 200 yds. to the left of Hill Sixty.

Our infantry had such a precarious hold on the edge of Mount Sorrel that every precaution was necessary. Behind us was nothing but low swamp through which it was quite impossible to make trenches. The natural thing for Fritzie to do was to try to blow us off the edge, and figuring that he would do the natural thing, we were ordered to put in a protective gallery to keep him back. Finding that our progress was too slow, the O.C. ordered us to start an incline from the front line, and we had no sooner reached the desired level (25 ft.) and commenced to drive horizontally than we ran into one of Fritzie's surprises, and he blew us, killing five men and wrecking our stair. This was very serious, as it showed us that he was already almost under our trench, and also was suspicious of us.

We then went about thirty yards to the right and left and started two inclines. Great care was taken to keep these saps secret, and strict quietness enforced. These were both driven down to the level required and galleries were driven out about 30 yds. We were then ordered to cross cut and connect. As these cross-cuts were expected to cut his gallery, our job was not very inviting, as we expected that he was patiently waiting for us to get near again to repeat his former kick. The officers in charge of this work adopted a very novel scheme which, although daring, worked all right. Work in each face would be stopped while a small bore hole was teased ahead about 25 ft., angling slightly outwards, then a very light charge would be placed in this hole and blown. Figuring that any listeners in the enemy galleries would have been chased away by the sound of the blow, our men would work like fiends for a couple of hours, when the ruse would be repeated.

In due course we cut his gallery and connected up our two stairs without losing another man. In this case our officers simply gambled on the probable effect of the blows on the Huns' actions and we won. It was considered quite a feat. After this the belt was continued with varying success till all the high ground was protected, about fifteen small mines being blown by each side. Sometimes Heinie caught some of our men, but we finally got the system finished as shown on plan. After this the company settled down to a long spell of fighting the Hun back from our line till June 7th, 1917, when, at the battle of Messines Ridge, every large mine on our front was successfully blown and tunnelling was ancient history.



MOUNT SORREL DEFENSE SYSTEM

While work was proceeding in offensive mining, the greatest thing necessary was to hear the enemy and not to let him hear us; therefore quietness was essential. This need of silence was the main reason why no mechanical devices were used. No one was permitted to wear boots in the galleries, the men mostly using sandbag slippers which they made themselves. The tunics were left off for fear the buttons would rattle on the timber, and all tools, timber, etc., which were carried through were swathed in sandbags to deaden any sound. No talking above a whisper was allowed.

Every 50 ft. along the main gallery, small listening pockets were driven off and bore holes radiated from the end. At the end of each bore hole there was placed a sealed torpedo containing 100 lbs. of ammanol, with an electric detonator and leads, and main leads were stretched down the main gallery from the office. Also each pocket had an electric

push-button connected to the office. Listeners lay in each pocket continuously, working in shifts of six hours on and twelve off. Each man had a geophone, which was a round wooden box, 3 ins. in diameter and 1 in. thick, containing a mass of mercury between two mica diaphragms, with ear connections like a doctor's stethoscope.

These geophones were very sensitive, and a good listener could pick up sounds of careless working through 16 or 20 ft. of sand, depending on its density. Practically the limit of hearing with the naked ear was 3 or 4 ft. Of course, in clay these distances were often much greater.

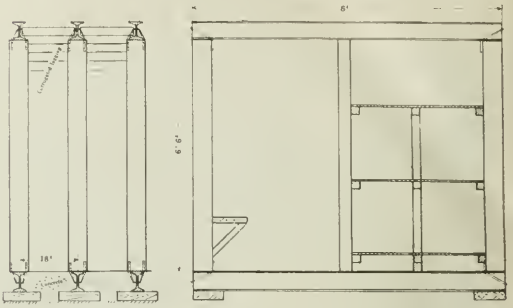
The leads from the torpedoes were carried out in gas-pipe tubes for protection, and if the geophone was placed in touch with the metal, the sounds were carried much better, so that when a listener heard a sound, he tried each pipe in turn, thus getting some idea of the direction of the sound. He then rang the bell, and either the officer on shift or the listening patrol would join him and confirm the sounds. Then the pockets on each side would be carefully tested and the source of the sound estimated. It was then necessary to determine whether the sound came from below or from above ground. This generally meant a few hours at night spent crawling around among the wire, etc., of No Man's Land to make sure the sounds did not come from wiring parties, or trench digging, or any other of the numerous noises of the night between the lines.

Entrance to German Gallery Near Vis-en-Artois

When we were quite sure that the enemy was underground, we noted the sounds in the log and waited. When he got close enough that we could hear him with the naked ear, we quietly stole away, connected up the main leads, tamped the gallery a little to secure it, and pressed the exploder. If we had been right, investigation would reveal our gallery all O.K., therefore the charge must have gone into the enemy's gallery, and the O.C., after investigation, patted us on the back and told us what fine fellows we were. On the other hand, if we found our own gallery smashed, it showed that we had had our "wind up" and blown a mouse or some other harmless noise, and the O.C. would say, "Hum! I guess Redan needs a new man. You ought to be retired in disgrace to a job where Fritzie couldn't reach you underground and given opportunity to think of your past failures."

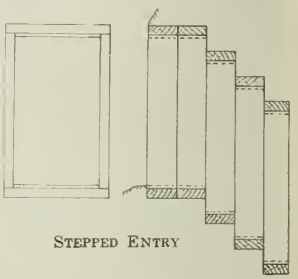
My greatest scare came from a mouse which had got down a bore hole; the rattle of its claws on the pipe exactly resembled the muffled scrape of a shovel. I had been called down by the listener and had lain in the dark for about two hours waiting for time to blow, the arrangement being that I would connect the leads, press the bell and the office would give me one minute to get back to safety before they would touch her off. However, when I had the leads all bared ready to connect (and I must admit that my hair was standing on end and I was sweating profusely, as I was quite sure Heinie was only three feet away), much to my relief I saw a small pink nose and two sharp ears appear at the mouth of the hole.

The desire to let the enemy get as close as possible, matched against the necessity of not letting him get in, to-



Type of Living Gallery Built by Canadian Troops

gether with the intense quiet and darkness, made the work extremely nerve-racking, and many men could not stand it for over three months. One night one of our men was too cautious about blowing, and Fritzie actually stole one of our torpedoes. Why he did not blow us we never knew, but he never got the chance again, as our flanking torpedoes were immediately blown, and as our gallery was untouched, we must have got him.

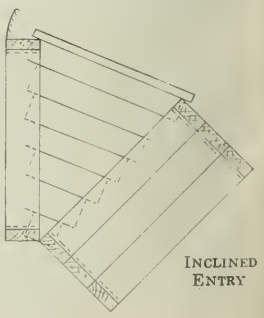


Stepped Entry

After a blow, very often the galleries would be filled with carbon monoxide, which is deadly, and so great precaution was always taken, a "proto man" being the first to enter the galleries after any trouble. The "proto man" was a man trained in the use of the proto, or mine-rescue apparatus. He usually went armed with oxygen tank on his back and a canary in a cage. If the canary fell off the perch, he knew there was carbon monoxide present, so he would strap on his mouthpiece, if it were not already on, and finish his investigation with artificial air.

Methods of Mining

The timber used in France for mining purposes was standard 3 by 9 in. spruce and pine, with some local elm when the supply ran short. Standard sets were made up in the yards, the inside dimensions being 2 ft. 3 ins. by 4 ft., 2 ft. 6 ins. by 5 ff., 2 ft. 6 ins. by 5 ft. 6 ins., 3 ft. by 6 ft., and 6 ft. 6 ins. by 6 ft. Most mine galleries were 2 ft. 3 ins. by 4 ft., and connecting galleries, 2 ft. 6 ins. by 5 ft. or 5 ft. 6 ins. Main galleries for passage of troops were generally 3 ft. by 6 ft., and living dugouts, 6 ft. 6 ins. by 6 ft.



Inclined Entry

In shallow work, that is, with less than 30 ft. of head cover, sinking and rising was carried out by the use of stairways and not shafts, 2 ft. 6 ins. by 5 ft. 6 ins. or 3 ft. by

6 ft. timber being used if the sets were stepped down, and 2 ft. 6 ins. by 5 ft. if the timber were set in the incline and steps placed later. This latter method was used by our company near the end of our work, as we found it the quicker method and also easier for keeping line and elevations. The sets of timber were made up of two legs and two caps or sills.

The caps and sills were supplied with spreaders nailed to the 3 in. by 9 in. timber against which the legs set, and so no nails were necessary to set the timber. The ground excavated was just a neat fit, except over the cap, which was one inch slack to allow for setting.

The Germans used a mortised end on their caps and legs, consisting of a ⅓ tongue, but this required a larger cut, and also was more noisy to handle, as they secured them with wedges, although this was not really necessary. We never made a practice of bracing the galleries, but in the dugouts, which were generally 6 ft. 6 ins. by 14 ft. long, we placed a centre support of two 3 in. by 9 in. timbers on edge, with 6 in. by 9 in. posts at centre and each end. Later, we placed a system of spreaders on top and bottom in order to resist the rebound or bump caused by the explosion of shells right overhead. The failure of many galleries and dugouts was due to the legs jumping the spreaders after a blow.

Construction of Galleries

When the ground was satisfactory, sets consisting of 8 ft. I-beams supported on pit props and secured to them by means of cast-iron chairs or hairpin clips (which were best, as they resisted bumping, which the cast-iron chairs did not), were placed at about 18-in. centres and then "lagged" with corrugated iron. This made a very roomy gallery, which we bunked with lumber and wire, three tiers of bunks, two-man wide, accommodating six men every 6 ft. 6 ins. of gallery. Some of these were concreted, and by driving air shafts to the surface about every 40 ft., we got very good ventilation.

When deep shafts were being sunk through quicksand, 4 ft. or 6 ft. steel tubing was used, the flanges being inside. This tubing was supplied in three segments. When the ground was good, these were sunk by digging out below and jacking down by the use of screw-jacks, the successive tiers of steel being bolted on at the top. The lower set was supplied with a flanged cutting edge. When quicksand was encountered, the whole thing was jacked down until solid ground was reached. As I never worked in a deep shaft, I cannot give a very accurate description of the difficulties met with in this work, although line was very hard to keep, due to a slight movement which sometimes existed in the sand, especially near the canal south of Ypres.

After the shaft had been sunk well into the clay or hard sand at the level desired, one segment of the lower tiers could be dropped out, leaving an opening to start the drift, or drive. Line was kept by the use of cross levels on the top, and also checked with a plumb-bob. The difficulties encountered in driving level and using timber sets were mainly due to quicksand just below the sills, and also to broken or shaken ground above the caps leading to a lost roof or cave-in.

Fore-Poling and False Sets

When the roof was allowed to drop, a method known as fore-poling was necessary in order to recover a solid roof. This consisted of driving stakes into the solid face in front, at an elevation above the top of the caps, and catching them on the top of the last set placed. Then the cavity was filled up with spoil in bags and packed until the roof was reached. The gallery would then be continued, the sets being placed under the poles which steadied the roof. If the cavity was not packed tightly, the roof would continue to shell off as fast as the face was removed. At times the ground at the face would not be strong enough to carry the fore-poling, in which case what was known as false sets would be used. They were sets placed inside the last set of the gallery, and sufficiently small to allow about 1½ ins. clearance, top and sides. Long lagging would then be driven through between these sets, angling outwards. After this timber had been driven sufficiently far into the ground ahead, wedges were driven between the inside ends of the lagging and the gallery timber. Thus the ground in front was held in place by the cantilever action of the lagging. The trouble with this method of procedure was that the gallery was very irregular in section, because the sets placed directly in front of the false set would be slightly smaller than the original section.

Pilot Galleries

Very often it was found very hard to drive a large face, although a small one would hold quite well. In ground of this nature a small gallery known as a pilot was used. This method consisted of driving a small gallery about the centre of the main face, and afterwards returning and enlarging it to full size, using the pilot timbers to steady the ground in front. In one case I found it necessary to use a second pilot, and as the gallery in question was being driven through a graveyard, the rum jar was a very necessary friend. A shot of rum every half hour barely sufficed to deaden the stench.

Working conditions seldom allowed one to pick his sight. In one connection made by our company it was found necessary to use false sets and to fore-pole the floor as well as the top and sides, the ground being semi-quicksand. Working in this ground was very unsatisfactory.

Vertical wooden shafts were sometimes used in good ground, the sets being placed at the bottom and hung by strapping to a collar set placed on the ground at the top.

So far I have only mentioned the difficulties met with due to the ground. It must be remembered that all the time the Hun was watching as closely as possible, and the moment he saw a bit of timber or fresh ground or blue clay, he turned all kinds of noisy messengers on to the locality. It was generally necessary to start work at night, and until every man was well below ground no work could be carried on in daylight, and all material would have to be carefully covered with sacking and sand before day broke. After sufficient cover was obtained, the spoil from the day shifts would be piled in the gallery in sandbags, and an extra party of men put on at night to clear it away and dump it, taking care to cover the fresh sand with surface sand before leaving.

Very often a face which seemed to be quite hard and firm would suddenly fall in, due to the shake of a big shell falling near, a condition never met with in civilian mining.

Surveying Under Difficulties

Most of the time our surveying was done with 4-in. prismatic compasses, and as some of the galleries were lined with corrugated iron, and dud shells were likely to be on any side of one, it can be seen that connections were very often made largely by guess. After our second year, however, we managed to get an excuse for a transit and a very good dumpy level, so we were able to make a few decent-looking connections.

The Dominion Iron & Steel Co., Ltd., announces that it has received an order from Rumania for 7,500 tons of specially shaped rails. Work on the order will commence in January.

The Asphalt Association, which has had temporary offices at 56 Church St., Toronto, for the past few months, has obtained permanent quarters in the Tyrrell Bldg., 95 King St. E., Toronto. The temporary telephone numbers are Main 4288 and 4289. The office is in charge of Bruce Aldrich, district engineer for the association.

The following officers were chosen by the Town Planning Association of Southwestern Ontario to serve for the ensuing year:—President, Ald. John Bridge, Windsor; first vice-president, W. A. Childs, Hamilton; second vice-president, S. Baker, city clerk, London; hon. secretary, Gordon Philips, London; hon. treasurer, John Cottam, London; executive committee, F. Maclure Selanders (Border Cities), J. McAdam (Sarnia), W. B. Burgoyne (St. Catharines), J. M. Shuttleworth (Brantford), and W. H. Breithaupt (Kitchener).

LARGE SHEAR-LEGS BUILT AT TORONTO

SHEAR-LEGS 80 ft. high, 35 ft. wide at the base, 10 ft. wide at the top, and with carrying capacity of 100 tons distributed equally between two blocks, were recently erected at the yards of the Dominion Shipbuilding Co., Toronto.

The two blocks allow both symmetrically and eccentrically loaded machinery to be carried horizontally with equal facility. The top girder also carries an auxiliary fall, of 10 tons' capacity, to take lighter weights.

The main legs are hinged at the bottom and allow the shear legs to tilt forward to a maximum, when loaded to capacity, of 50 ft. overhang from the base. When carrying 50% of the full load, the overhang may be increased to 60 ft. The 50-ft. overhang is sufficient to allow machinery to be placed in the centre of a boat or on the side away from the shear-legs.

In order to obtain strength without excessive cost, latticed steel construction was decided upon for both main

SHEAR-LEGS BUILT FOR DOMINION SHIPBUILDING CO.

and back legs. The top girder is of steel plate. The main legs have a maximum dimension of 4 ft. square at the middle, tapering to 18 ins. square at the ends. All the legs are strengthened by diaphragms.

The shoes and hinges are of cast steel and are embedded in concrete. The back guys are 2-in. plough steel cables, which are each attached to a quadruple luffing tackle which is anchored to a 4-in. steel pin buried 10 feet deep in concrete.

The steel hoisting blocks are 15 ins. in diameter. Each of the four 50-ton blocks have six sheaves, carrying ¾-in. plough steel cable. These cables are connected to the hoisting machinery by way of underground ducts.

The hoisting speed of the 50-ton blocks is 6 ft. per min., and they are operated by a four-drum electric hoist, equipped with a 60-h.p. motor. This hoist also operates the luffing tackle. Two drums of the hoist are in series and two in multiple. There is a special single-drum electric hoist, with a 60 h.p. motor, for operating the 10-ton block with speeds up to 50 ft. per min. These hoists have automatic brakes and band brakes on the drums. Cut steel gears were used throughout, with the exception of the main gears on the drums, which are of cast-iron.

The shear-legs were fabricated by W. D. Beath & Sons, Ltd., and McGregor & McIntyre, Ltd., both of Toronto and were supplied to the Dominion Shipbuilding Co. through

VIEW SHOWING HOIST HOUSE AND LUFFING TACKLE

F. H. Hopkins & Co. The design was suggested by the engineering staff of the Dominion Shipbuilding Co. and was detailed and elaborated by C. V. Osborn, Toronto manager of F. H. Hopkins & Co., and by Harry Brass, engineer for W. D. Beath & Sons, Ltd.

At the annual meeting of the Border Cities branch of the Engineering Institute of Canada, the following officers were elected: Chairman, H. B. R. Craig; secretary-treasurer, J. E. Porter; executive, J. J. Newman, H. Thorne and Ed. Brain.

J. M. Leamy, provincial electrical engineer of Manitoba, states that construction on the first lignite briquetting plant in Western Canada will commence early in the spring. The plant will be located six miles southeast of Bienfait, Sask., on a spur of the C.P.R. All the buildings will be of steel construction.

With the object of promoting a highway from Fort William to Winnipeg, a new organization, to be known as the Central Canada Colonization and Highway Association, has been formed. Out of a total mileage of 423 miles, 60% will have to be brought up to a "good roads" standard and connected to sections already constructed. The suggested road would open about 50,000,000 acres of land that are at present undeveloped.

In Alberta and Saskatchewan, about 54,000,000 acres of land require irrigation, says the superintendent of the Dominion reclamation service. A further area of 19,000,000 acres, lying between the North and South Saskatchewan and the Battle and Deer rivers, is declared by engineers to be irrigable. At the present time about 1,500,000 acres are irrigated, and the Dominion government has promised immediate surveys of another 500,000 acres which will be irrigated at an estimated cost of $20,000,000. The Canadian Pacific railway has developed in Southern Alberta the largest individual project on the American continent, with an irrigable area of 600,000 acres, and canals and ditches having a total length of over 3,000 miles.

$6,000,000 SEWERAGE SCHEME RECOMMENDED FOR WESTERN PART OF YORK TOWNSHIP, ONT.

COMPLEMENTARY to the report on the sewerage scheme for the eastern division of York Township, Ont., which was published in last week's issue of *The Canadian Engineer*, is the report which has just been submitted by the township engineer, Frank Barber, and his associate, R. O. Wynne-Roberts, planning a sewerage scheme for the western division of the township at an estimated expenditure of about six million dollars. The following information is abstracted from the report:—

The topography of the western division, which includes that part of the township from Oriole parkway on the east to the Humber river on the west, but excludes the subdivisions which are located north of St. Clair avenue, Toronto, near Jane street, is such as to render it impossible to design a scheme similar to that proposed for the eastern division, where the engineers recommend one large sewerage system capable of being divided into sections which could be constructed as required. The general inclination of about half of the western division is south and southeast towards the city of Toronto, the other half tending to fall southeast towards Black creek.

It would be impossible to drain the sewage and roof water from most of this division towards Black creek, but when storm water has also to be disposed of, then the dimensions, and therefore the cost, of the sewers become prohibitive. Consequently, it has been considered advisable to split the division into ten sections, of which all but one will have a combined system of sewers for sewage and storm water.

The proposed sections, which are localized by their names, are as follows: (1) Bathurst, (2) Cedarvale, (3) Oakwood, (4) Silverthorne, (5) Eglinton, (6) Roselawn, (7) Bedford Park, (8) Upper Black Creek, (9) Lower Black Creek, and (10) Mount Dennis.

1. The Bathurst section, which is described as the district lying east of Forest Hill road and Bathurst street, from the vicinity of Upper Canada College to Wilson street, has an area of 1,030 acres, and drains naturally towards the city of Toronto by streams flowing southeast to the Don river.

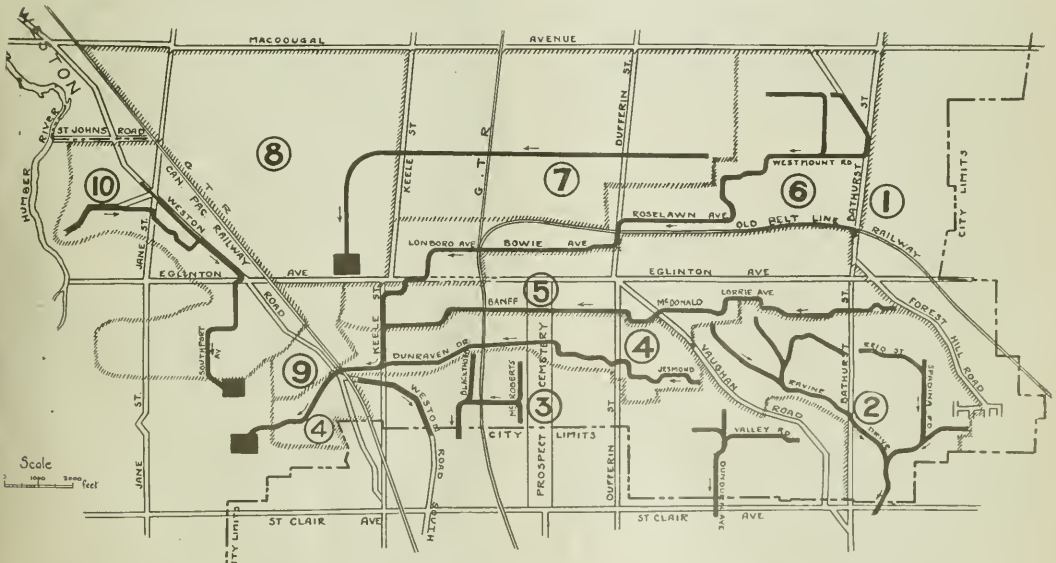
The watersheds of these streams have a total area of 3,544 acres, and are tributary to the natural water-courses passing through North Toronto. As provision was made for the drainage of the natural run-off from these watersheds into the proposed trunk sewers for the North Toronto drainage system, the engineers recommend that the Bathurst section should be sewered into the city system.

The estimated cost of sewers is $920,000 for trunk sewers and $616,000 for laterals, which, based upon 30-year 6% debentures for trunk sewers and 10-year 6% debentures for laterals, would indicate an annual capital cost of $149,000, or $112,000 if based upon 30-year 6% debentures for the whole work. On a frontage basis, this amounts to 48 cents and 37 cents per foot respectively, and adding the city's present charge of 23 cents per foot for outlet rental and maintenance, the amount is 71 cents per foot per annum.

2. It is proposed that the Cedarvale section shall extend from Forest Hill road on the east to Vaughan road and Oakwood avenue on the west, and from the Toronto city limits on the south to Dearborne and Lorrie avenues on the north; this comprises about 530 acres. The natural outlet for the sewage and storm water is to Rosedale creek, and the works commissioner of Toronto stated in 1915 that a portion of the section could be drained into the Rosedale creek sewer.

The total area of the watershed of Rosedale creek is 2,100 acres, with a runoff towards the city of Toronto. The city authorities are bound to accept the natural flow, but they contend that they are not responsible for the disposal of sewage or streams when houses are built and streets are graded and paved. The York Township engineers consider that the city of Toronto should provide outlet facilities for the sewage and storm-water from the Cedarvale section, with the understanding that three trunk sewers shall be constructed across the watershed when required in the future, namely, on Dearborne and Lorrie avenues for the Eglinton section, on Roselawn for the Roselawn section, and on Park road for the Bedford Park section, these trunk sewers to act as interceptors and to divert the storm-water to Black creek, thus limiting the discharge into the city of Toronto to that from the Cedarvale section solely.

The cost of sewers in the Cedarvale district is estimated at $422,000 for trunk sewers and $342,000 for laterals, with an annual capital cost of $77,000 or $56,000 (equivalent to 50 cents or 37 cents a foot), depending upon whether 30-year 6% debentures are considered for trunk sewers only or for the whole system. The addition of the annual charge of 23



PROPOSED SEWERAGE SCHEME FOR WESTERN DIVISION OF YORK TOWNSHIP, ONT.

cents, which may be increased, brings the estimated cost of construction of these sewers to 73 cents per foot frontage per annum.

3. The Oakwood section comprises the area lying between Vaughan road, Wilmington, Hanson, Donald, Eversfield, Hatherly, Summit and Aileen avenues on the north, Bathurst street on the east, the Toronto city limits on the south, and the railway on the west.

It is stated that nineteen avenues have sewers for part or the whole of their lengths, and as it is considered inadvisable to make any change which would complicate the system, a recommendation is made that the sewers required for the remainder of the streets in Oakwood section should connect with the city sewerage system. About 520 acres in this district must be sewered at a cost of about $520,000, or an annual capital cost of 44 cents per foot frontage on a basis of 10-year 6% debentures. The total charge, including the rental, amounts to 67 cents per foot per annum.

The points of connection can be arranged to suit the city sewerage system, but the tentative location of these connections are shown in the accompanying plan. The works commissioner of Toronto has stated that the city can accommodate the combined flow from about 204 acres, but it would be necessary for the township authorities to construct a storm sewer paralleling St. Clair avenue from Ossington avenue to the Rosedale creek sewer.

4. The Silverthorne section, with an area of 360 acres, must be drained into Black creek, and for that purpose a trunk sewer is proposed, to be built along Wilmington, Jesmond, Harris, Westmount, Martin, Holmesdale, Chudleigh and Harvey streets, thence to Dunraven, Keele, Elora and Northland streets, with a storm sewer relief to Black creek which will intercept another storm sewer flowing from the north.

The cost of this scheme will be approximately as follows: Trunk sewers, $364,000; laterals, $219,000; share of cost of disposal works, $110,000; total, $693,000.

The annual capital cost is estimated at $64,000, or 59½ cents per foot when based on 30-year 6% debentures for trunk sewers and 10-year 6% debentures for lateral sewers, and $51,000, or 47 cents a foot when calculated upon a basis of 30-year 6% debentures for both.

5. The proposal for the Eglinton district, including 620 acres, includes a trunk sewer (with an outlet at Black creek) flowing along Dearborne, Pellatt, Sutherland, Lorrie, Clovelly, Leroy, Carrington, Banff, Commodore, Silverthorne, Ewart and Keele streets, and joining the sewer from the Silverthorne section at Dunraven avenue, with a storm water relief to Black creek. This will intercept the storm water and sewage flowing to the north as far as the Belt Line and Bowie avenue.

The estimated cost of this scheme is: Trunk sewers, $632,000; laterals, $422,000; share of cost of disposal works, $190,000; total, $1,244,000.

The annual capital costs, figured on the same basis as for previous sections, are $112,000 or $91,000, or (expressed in terms of foot frontage) 60 cents or 49 cents.

6. Roselawn district similarly drains to the Upper Black creek, and a trunk sewer is suggested along Roselawn, Bowie and Lonborough avenues, discharging into the disposal works on the creek. A subsiding trunk sewer will follow Fourth street, Stayner and Summerhill avenues and Westmount road. The total area to be drained is 630 acres.

7 and 8. The township engineers consider that sewers for the Bedford Park and Upper Black creek districts, the former with 860 acres and the latter 1,000 acres, would be very far in advance of present needs, and as conditions may change in those sections before the sewers are required, no estimates have been presented for those two districts. The engineers state that the main feature to be established is the trunk sewer, and the direction of this is indicated on the accompanying plan.

9. The Lower Black creek section has an area of 100 acres, and is bounded on the north by Eglinton avenue; on the south by Elora to Cripps; on the east by Walter, Juliet and Bicknell avenues; and on the west by the railway tracks to Jasper and Symes avenues.

The section is too low-lying to permit the sewage being discharged by gravity into the trunk sewers which pass in the vicinity, and pumping will be required at the disposal works. The estimated cost of this scheme is about $145,000, as follows: Trunk sewer, $20,000; lateral sewers, $60,000; pumps and wells, $5,000; share of cost of disposal works, $30,000; storm sewers, $30,000; total, $145,000.

Estimating the annual fixed charge on a basis of 30-year 6% debentures for trunk sewers, disposal works and storm-water system, and 10-year 6% debentures for laterals, pumps and wells, with a maintenance, power and repair charge of $2,200, it amounts to $16,661, or $13,043 if on a basis of 30-year 6% debentures for all works. The estimated cost per foot frontage is 55 cents in the former case and 44 cents in the latter.

10. The Mount Dennis district includes all the territory west of the railway tracks, south of Weston limits, east of Humber river and north of Black creek, and has an area of 440 acres exclusive of low-lying gardens. It is proposed to drain this area to a disposal plant situated in the Black creek valley, to the north of the creek and east of Southport avenue. The estimated cost of the scheme is $836,000, and the annual capital cost would be about 59 cents per foot of assessable frontage, or 45 cents per foot if the laterals be based upon 30-year debentures.

When the flow of sewage exceeds three to six times the average flow, the surplus will, where possible, be discharged into relief sewers, but the cost of these are not included in the foregoing schemes, because the sewers already designed are ample for a long time.

The surplus over six times the normal flow will be discharged into the stream, which will at that time be in flood, and consequently no harm can then be done. Consideration was given to every means for enabling all the sections to have one joint sewage disposal works, but this had to be abandoned owing to the difficulties of arranging for the trunk sewers to cross the different valleys at satisfactory grades and on account of the cost of such trunk sewers.

Consequently, at present it seems necessary to have two disposal plants for the western division, one in the Lower Black creek valley for the Silverthorne, Eglinton, Roselawn and Mount Dennis sections, for which 20 acres of land will be necessary, and one in the Upper Black creek valley for the Bedford Park and Upper Black creek sections, which will require about 18 acres of land.

The method of treating the sewage will be either by means of tanks and filters or by the activated sludge process. The disposal works will, of course, be built according to the requirements from time to time, and the whole sewerage scheme is so arranged that any portion can be carried out, provided the work proceeds from the outlets. The entire works will not be completed for several years at least, but it was deemed advisable by the authorities to have comprehensive plans outlined for the sewerage of the entire township, so that any sections that are built will fit into a definite general scheme.

Representing 53 boards of trade, the annual meeting of the Ontario boards of trade adopted without opposition a resolution urging the desirability of the Ontario government's carrying on a highway scheme "until the province is a network of good, substantial roads serving the communities with economy and efficiency, and adding greatly to the comforts of life."

The Light Commission of Kitchener, Ont., which operates the electric and gas plants, as well as the Kitchener & Waterloo street railway, states that it has to solve the problem of providing within the next few months at least 100% more power than is at present supplied. The members are opposed to the hydro-radial by-law, which is to be voted on on New Year's Day, being of the opinion, that when the Chippawa development is completed, the demand for domestic, commercial and industrial power will utilize the 450,000 h.p. that will be developed, without radial railways.

G. B. GREENE HEADS OTTAWA BRANCH, C. B. & C. I.

AT the annual meeting of the Ottawa branch of the Association of Canadian Building and Construction Industries held December 10th, G. B. Greene, general manager of the General Supply Co. of Canada, Ltd., Ottawa, Ont., was elected president.

Other executive officers chosen for the ensuing year were: Vice-president, H. Graham (general contractor), J. L. Douglas (trade contractor) and R. Hooper (supply man); honorary treasurer, E. M. Barrett; and honorary secretary, G. A. Crain.

In addition to many prominent contractors, there were present several members of the Board of Trade, including the secretary, Cecil Bethune, and E. R. Bremner, both of whom addressed the meeting. F. B. Belfry spoke on behalf of the Ottawa Housing Commission, urging greater interest on the part of contractors in the work of that body.

TORONTO HARBOR COMMISSION'S WORK

BETWEEN the years 1912 and 1918 the Toronto Harbor Commission accomplished works amounting to $9,764,800. From the Dominion government 257.5 acres of water lots were acquired by patent; the commission also acquired 4,700 ft. of frontage or riparian or water rights between Bathurst and York streets. Business and industrial properties and parks required the handling of 16,000,000 cu. yds. of material in reclaiming 1,057 acres of water lots and marsh lands.

Approximately 2½ miles of commercial dock walls were constructed, which, with the exception of the Don retention walls, are in the inner harbor.

At the eastern harbor terminal, the work done includes 11,630 ft. of sidewalks, 9,350 ft. of concrete pavements of various widths, 9,500 ft. of storm sewers from 12 ins. to 42 ins. in diameter, and 4,500 ft. of overflow sewers (sizes 6 by 18 ft., 6 by 16 ft., and 6 by 8 ft.).

NATIONAL HIGHWAY TRAFFIC ASSOCIATION

AT the annual convention of the National Highway Traffic Association, which is to be held January 29th, 1920, in Chicago, the morning session will be devoted to the reading of reports of committees on highway transport franchises; interrelationship of highway, railway and waterway transport; traffic limitation strips on roadway surfaces; and sign posting for detours and through routes to municipalities; and an address by George W. Tillson, consulting engineer, La Grange, Ill., on "The Effect of Car Tracks on Traffic Capacity of Roadways."

"Highways and Motor Transport" will be the general theme of discussion at the afternoon and evening sessions, which will be joint sessions of the National Automobile Chamber of Commerce and the National Highway Traffic Association. The addresses to be delivered include: "Taking an Interest in Motor Truck Legislation," by Harry Meixwell, Jr., secretary, Automobile Industries Legislative Commission, New York; "Value of Highway Transport Surveys," by F. Van Z. Lane, transportation engineer, Packard Motor Car Co.; and "Interrelationship between Highway Transport and the Back-to-the-Farm Movement," by L. C. Hargreaves, of the Goodrich Rubber Co.

Arthur H. Blanchard, of the University of Michigan, who is president of the association, will speak on the "Relation of Highways to Motor Truck Operating Cost," and William G. Edens, president, Illinois Highway Improvement Association, on "Progress in Highway Improvement."

"Constructing Roads for Motor Truck Traffic," is the title of a paper by Prof. T. R. Agg, Iowa State College. Raymond Beck, chief of the Goodrich National Touring Bureau, will discuss the "Status of Legislation Relative to Snow Removal from Interstate and Intrastate Highways."

COMPUTING CROSS-SECTION AREAS BY THE METHOD OF CO-ORDINATES

By J. A. McDonald
Provincial Land Surveyor, Hermanville, P.E.I.

IN spite of its simplicity, the computation of areas by the method of co-ordinates is not often practised by engineers and surveyors. In the following article a formula is obtained for a given area in terms of its co-ordinates, and a general formula derived which is applicable to a cross-section area of any shape.

Referring to Fig. 1, the area of the figure 1234 is equal to the trapezoids $(a12b)+(b23c)-(a14d)-(d43c)$.

Expressed as an equation in terms of the co-ordinates:—

$$\text{Area } 1234 = (y_1-y_2)(x_1+x_2)/2+(y_2-y_3)(x_2+x_3)/2-(y_1-y_4)(x_1+x_4)/2-(y_4-y_3)(x_4+x_3)/2$$
$$= \tfrac{1}{2}[y_1(x_2-x_4)+y_2(x_1-x_3)+y_3(x_4-x_2)+y_4(x_1-x_3)].$$

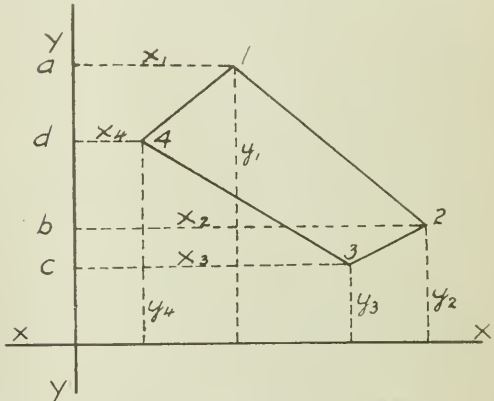


FIG. 1—DIAGRAM FOR CALCULATING AREA BY METHOD OF CO-ORDINATES

From this equation is derived the following rules for obtaining the area when the co-ordinates are given:—

(1) Number the corners consecutively.

(2) Multiply each ordinate by the difference between the abscissae of the points preceding and succeeding, and take half the sum of these products.

The adoption of this method in computing railway and other earth cross-sections is quite simple. The cross-section

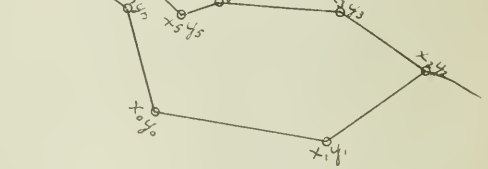

FIG. 2—DIAGRAM SHOWING GENERAL APPLICATION OF FORMULA

is considered as an area all of whose co-ordinates are known; the cuts or fills are represented as ordinates and expressed in terms of y, whilst the distances out from the centre become abscissae, and are expressed in terms of x.

The general formula for any possible shape of cross-section whose area is A would be (Fig. 2):—

$$A = \tfrac{1}{2}[y_1(x_1-x_n)+y_1(x_2-x_1)+y_2(x_3-x_1)+y_2(x_1-x_2)+y_3(x_5-x_3)+y_5(x_6-x_4)+y_6(x_7-x_5)+y_7(x_8-x_6)+y_8(x_9-x_7)].$$

The application of this formula is by no means so difficult as the formidable appearance of the above algebraic statement would indicate.

When making use of this formula, it may be advisable in figuring the first few sections, to draw rough sketches of the sections in order to ensure taking the points in correct order; a very little practice will enable an engineer to compute the areas directly from his cross-section notes.

The formula is not an approximation, as are the slope and other formulæ, but is mathematically exact and applicable to every kind of section.

The following directions should be followed:—

"Begin at any point on the section and proceed in either direction (clockwise or counter clockwise), multiplying each cut (or fill) in its order by its horizontal distance between the point just preceding and the point just succeeding. In cases where one passes to the right in measuring the horizontal distance from the preceding to the succeeding point, the product obtained by multiplying this distance by the cut (or fill) at the intermediate point is of one sign, and in cases where one passes to the left, it is of the opposite sign. Take one-half the difference between the sums of the products of opposite signs, and the result is the area of the section."

Thus, in a side-cut where only the slope stake reading and the intersection of the earth surface with the grade-line are taken, the area is a simple triangle, and the application of the formula to the computation of the area would seem to require three multiplications.

Two of the points, however, are on the grade-line and the cut (or fill) is zero, hence the product is zero; the formula, therefore, results in a single multiplication and taking one-half the product of the cut and width.

In the case of the so-called "three points" or "three level" section, which is a section actually containing five points, two multiplications are eliminated in a similar manner.

The outside slope points can be worked together by taking the sum of these cuts (or fills) and multiplying by one-half the width of the roadbed.

Many useful and interesting features of the application of the formula become apparent as its use is extended.

Letter to the Editor

TRADE UNIONISM AND ENGINEERS

Sir,—I have read, with much interest, the letter on "Trade Unionism and Engineers," by Fred Christie, in your issue of December 18th, and I think he voices the sentiments of all engineers who do the work and are not the engineers who employ other engineers.

Mr. Christie is evidently not of that class of engineers who are afraid to speak of conditions as they exist. The engineers at present supposed to be in the control of the large engineering societies are mostly in the employ of corporations or are employers of engineers of their own. Many of the so-called leading engineers are "leading" because they control the living of other engineers, and the leaders could not hold their jobs unless they kept wages down.

If engineers are afraid of trade unionism, what about the methods that are used against them? These are the old methods used against the union men in former years, but which the employers no longer dare use. For instance, thirty of the leading engineers wanted to have a committee meet their employer and discuss pay. Would he receive the committee? Not so that you would notice it. He received the paid representative of the men who cleaned out his premises, but not the committee of his engineers.

The pay of the engineers has been raised less than 20%, while the scavenger has been raised 150% or more, and in some cases is getting nearly as much as the engineers. Force must be met with force, and the individual engineer negotiating with the employer is a joke. The engineer has no business education, is usually in debt for his schooling, and has a family, but in general has to assume the attitude of a supplicant instead of a freeman.

Some engineers are now in charge of $2,000,000 worth of various work in a year, and get less than $3,000. I paid an armature winder $66 for last week's work and hope to pay him more next week; the more he makes, the more I make. But the machine he wound was designed by me on a $23-a-week salary and an education that cost me $10,000 and seven years' time! That was some years ago, but the engineers in the same place are really getting less than that now, so far as the purchasing power of their money goes.

Dignity is all right, but when you have to hold off the grocery man, dignity is no good. How can a man with a college education be dignified with from $1,500 to $3,000 these days?

A salary of less than $5,000 a year is no good for dignity, and few engineers are getting that or ever will get it until they belong to some organization with "sand."

The sooner the engineers join a union, the better for all,—employers of engineers included. A man cannot work when he is only one jump ahead of the sheriff.

Another thing is this: The employer, while he will not pay the experienced engineer a decent salary, will pay a set of dubs three times as much to do the same work; that is, he gets six men at a low pay to do one man's work, and pays them in the aggregate three times as much as he would have to pay the one man. This has happened and is happening many times.

Some big companies have engineers by the dozen doing work that anyone with even less than a high-school education could do. Of course, it is a good idea to have a lot of technical men doing clerical work; they know what the words mean; but clerical work gets clerical pay, no matter who does it, and until engineers doing clerical work catch onto themselves, so long will they get clerks' pay.

The remedy for this is to exclude clerks from engineering societies; they are doing menial work, and not engineering work. The idea is that they are in line for promotion, but for 95 out of 100 there are no good jobs.

In the average large engineering establishment there are not over three good paying jobs and they are held for 40 years or so by the same men. What chance is there of promotion?

Many engineers now make a specialty of marrying rich girls or daughters of their employers, and in this connection I have never known of an engineer who married the daughter of his employer who failed to have the best job in the place. I suppose the business acumen he displayed in getting the girl is what got him the job, but I doubt it.

Never have I known an engineer, a hired one I mean, to get a good job without some influence other than his ability. The members outside of the influential circle can get into one by some kind of an organization doing its business with a paid representative, and by no other way. The ordinary engineer negotiating with his employer on the salary question is a joke.

N. C. MILLS,
Vice-President and Managing Director,
Montreal Armature Works, Ltd.

Montreal, Que., December 20th, 1919.

During the fiscal year 1918-1919, work was done in the province of Quebec on 904 miles of road, which included 282 miles of completed roads and 292 miles of winter roads. An aggregate of 16,580 ft. of bridges and culverts were also built by the highways department. The total amount expended during the year was $530,935.

In order to provide water and electric power for Palestine, Albert Hjorth, a Norwegian engineer, suggests a tunnel 37 miles long, from the Mediterranean to the Dead Sea, passing under Jerusalem, with power plant on the shores of the Dead Sea, and a pumping station on the Sea of Galilee. The initial cost would be $40,000,000. The surface of the Dead Sea is 1,300 ft. below sea level, and that of the Sea of Galilee, 650 ft.

Economic Values in Sewage and Sewage Sludge

Grease in Dried Sludge, or Tankage, Makes Its Assimilation by Soil Very Difficult—Sludge Must Be Acidulated with Mineral Acid and Percolated—Adaptation of Cobwell Process—Address to American Society for Municipal Improvements

By RAYMOND WELLS
Chemist and Technologist, Homer, N.Y.

WHAT is sewage sludge? Is it just a plain nuisance—something to be sunk, burned or buried—or is it just a very unattractive mass of low-grade raw material offering slight potentialities in economic values, provided of course that they can be liberated?

Much sleep has been lost by enthusiasts in both directions. It is unnecessary to say that for many years the fertile brains of inventors, engineers and chemists have been directed toward methods of restoring to the economic cycle all or any portion of the values contained in sewage or sewage sludge. Unquestionably vast quantities of valuable materials are present in sewage, but so great is the dilution in the carrying medium, and so dangerous to the public health is any delay in rendering it innocuous, that methods of recovery so readily applied in other waste reclamation are not applicable to sewage or sewage sludge.

The net result of all labor and thought along this line seems to have been the accumulation of a great deal of knowledge of what cannot be done, and as yet there is no method in actual operation on a large scale for recovering anything of value, or indeed offering any reasonable disposition of the sludge problem.

The apparently most patent and logical disposal of sludge would be the direct recovery of manurial values by direct application to the land. Water, however, is an expensive thing to transport in wagon bodies, and a grease-soaked fertilizer is difficult of assimilation by the soil, and constant application of such material invariably destroys soil texture.

Partial elimination of moisture by bed drainage and drying, followed by incineration, has offered a more or less practical and expensive disposition of the sludge, with of course no values recovered.

Colloidal Character of Precipitate

Partial elimination of moisture by filterpressing or centrifuging, followed by drying, would seem to be the simplest method of putting sludge into a valuable form. But unfortunately the almost colloidal character of the precipitate and the amount of grease and metallic soaps contained render pressing and centrifuging below 75% to 80% of moisture a difficult task. The subsequent evaporation of so great an amount of water in any type of drier is most expensive and the odors given off are extremely disagreeable. Furthermore, in direct heat driers, the volume of gases of combustion, together with the moisture-saturated air, is so great as to preclude any thought of condensing or scrubbing out the odors. For this reason alone, aside from the difficulties encountered in drying such a material, it is difficult to see any hope of solution in this direction.

Furthermore the dried residue or tankage obtained by this method, while having considerable manurial value, is in a most undesirable condition for use as fertilizer or fertilizer base-goods. This is due to the grease contained, which, when it exceeds 8% in any tankage, renders its assimilation by the soil extremely difficult.

To really complete the cycle of operation, the dried sludge should be percolated, grease removed and the percolated tankage redried. Since, however, a large percentage of the grease present is in combination with alkaline earth and metals in the form of metallic soaps, it renders solution by simple percolation impossible. For this reason it is necessary to acidulate the sludge, prior to percolation, with some mineral acid, so that the fatty acids combined with metals as soaps will be liberated and put in such condition that they will be soluble in the usual solvents employed in percolation.

This acidulation would have to take place prior to the drying operation, in suitable lead-lined digesting apparatus, and no matter how carefully this operation were carried out, the wear and tear on the drying apparatus and the percolator, due to acid action, would render the operation very expensive and troublesome. Not only would the apparatus employed be very short-lived, but the action taking place between the liberated fatty acids and the grease in immediate contact with even a trace of mineral acid at high temperature, would crack the fatty materials so badly as to render them valueless.

This was very evident in attempts by the writer to handle samples of sludge made by the acid, or Miles, process, by direct drying. At a certain point where most of the moisture was eliminated, charring took place, with copious evolution of sulphur dioxide and acrolein vapors, and the grease obtained by subsequent extraction and distillation gave an extraordinary amount of tar and unsaponifiable matter.

Percolation and Redrying Unsuccessful

Not only does this reaction take place in the drying operation, but the solvent carrying the grease also carries with it small traces of mineral acid which must be carefully washed and settled out before distillation for recovery of solvent. If this is not done upon approaching a certain concentration in the still, violent foaming, with evolution of sulphur dioxide and fatty decomposition products, takes place and again the grease is damaged. It may be well to note that the mineral acid referred to is, of course, sulphuric acid, no other acid being available, on account of price, for use on such low-grade raw material.

For the above reasons, the operation of drying, percolating, redrying, etc., so readily applied to other materials, seems not to be very successful when used on sewage sludge.

Destructive distillation of the dried or semi-dried sludge has been attempted, with the usual methods of recovery of the ammoniacal liquors and oils. Here again the problem of moisture elimination is intruded, and the recoveries made are not such as warrant the hope of even paying for the operation, much less of showing any profitable return. In the case of distillation both of dried sludge and of garbage tankage, the experiments of the writer have in all cases failed to show a greater recovery of nitrogen in the ammoniacal liquors than 35 to 40% of that present in the original samples. As a rule, an additional 30% remains in the retort charcoal, with the residue passing off as nitrogen in the combustible gases. The oils passing over are of little value except as fuel. This appeals to the writer as being a very expensive way of producing fuel oil.

Acidulation of semi-dried sludge from filter-presses or centrifuges, followed by drying in retorts, with subsequent distillation in current of superheated steam to carry over the fatty acids liberated by acid, has been tried but found unsatisfactory for many reasons.

Methods have been described and tested out on a large scale, attempting the direct extraction of greases from wet sludge by volatile solvents. In these processes, which are difficult and expensive to carry out, a partial solution of the free grease results, together with a portion of the waxes and soaps existent in sewage. The result is the formation of extremely resistant emulsions which seem to defy any recovery treatment by distillation. After such an emulsified mass has reached a certain concentration in the solvent

recovery stills, the whole charge expands into a foamy mass of which, seemingly, a gallon will fill a large tank.

An endless number of methods and schemes have been tried, first and last, but apparently none had sufficient merit to survive the first attempts. Possibly many failed under market conditions which do not exist at the present time; or, what is more likely, at their beginning they promised so much that mere partial success gave nothing but discouragement.

Leaving the recovery method aside for the moment, are there any—and if so what are—the inherent values of sewage sludge? What type and condition of the sludge offers the greatest possibilities?

Grease and Nitrogen Content

Setting aside for the present the moisture content, the value of the sludge will be governed by its grease and nitrogen content. While all sludges contain small percentages of bone phosphate and potash, from a practical standpoint they may be neglected. Consider the following analyses (dry basis):—

	Ammonia	Grease
Baltimore sludge, acid process, fresh, ..	3.26%	27.23%
Boston sludge, acid process, fresh, ...	3.91%	29.30%
Chicago Sanitary District, activated sludge, fresh, ...	5.10%	14.70%
Pleasantville, N.Y., settling basins' sludge, one month in basins, ...	4.14%	27.40%
Syracuse settling basin's sludge, fresh, ..	4.02%	9.60%
Syracuse activated sludge, fresh, ...	5.06%	17.70%

All of those analyses are from samples of sludge produced from comparatively fresh sewage and are representative of sludge rapidly deposited and not allowed to rest in the tanks for any great length of time. For that reason little bacterial action had taken place and the ammonia and grease content are at their maximum for the different types of sludge. Compare with those, these analyses of samples of sludge from so-called septic tanks or sludge which has been exposed for a great length of time on drying beds:—

	Ammonia	Grease
Baltimore sludge (from tanks) on bed approximately 6 months, ...	2.34%	1.50%
Chicago, activated sludge, 9 months old, ...	4.40%	5.00%
Akron, O., sludge, 3 months in tank, 6 months on bed, ...	1.00%	6.00%

All other things being equal, the value of a sludge for by-product recovery purposes depends upon the shortest possible period of tanking and shortest elapsed time between tank and ultimate utilization. In other words, bacterial action and weather erosion must be restricted to a minimum. This is directly contrary to usual sewage practice and is one of the rocks on which the disposal proposition has stumbled.

Minimum Value Worth Recovering

Below a certain minimum of recoverable values, there is no use attempting recovery. This minimum seems to be, for low-grade ammoniates such as garbage tankage and sewage sludge, approximately 3% ammonia. Below this the expense of handling and freight cost put it out of all hope of competition with other and more concentrated materials. From an economic and business standpoint, any goods falling below this rating had better be forgotten and no time wasted on developing methods of handling.

Moisture content of sludge leaving tanks is the next most vital consideration. In order to come within economic range of any method of artificial drying of any material containing 3 to 3.3% ammonia and 10 to 15% grease on dry basis, moisture must not exceed 75 to 80%. All sludges as they come from tanks or basins are far above this, and activated sludge way beyond. Sludge from ordinary sedimentation basins can be drained and air-dried within several weeks to 77 to 80% moisture, and by centrifuging to about the same amount. It would appear, however, that the simplest and most inexpensive method is that of depositing sludge, after removal from tanks, on drainage beds exposed to atmospheric drying conditions. In any case, without the presence of water dumping facilities, the sludge must be partially dewatered before final disposition.

With sludge containing 75% moisture, the ultimate disposition with by-product recovery is not impossible, though difficult and presenting many curious conditions.

To accomplish the disposal with production of a marketable tankage and grease, the elimination of all of the moisture with subsequent extraction of the grease by volatile solvents, a system of drying, extraction and recovery in one operation is suggested. Such a combined and complete operation is carried out at the present time only by the Cobwell process.

This process, as is doubtless well known, is applied to the handling of municipal garbage, dead animals, slaughterhouse offal and other wet organic waste materials. At the request of several engineers and municipal officials, a number of small-scale and several large-scale experiments have been undertaken and carried out on sewage sludge, with results which seem to warrant some hope of solution of the problem.

Adaptation of Cobwell Process

It is unnecessary to go into any detail in description of a process with which most engineers are familiar. But some variations are required in applying it to handling of sewage sludge.

In this method of dehydration with simultaneous degreasing, the principle employed is that of desiccation in a hot bath of an immiscible solvent which shall serve not only as a dehydrating medium but shall also, during the period of drying, continually dissolve the grease contained in the material to be dried.

Such a solvent preferably employed in the handling of sewage sludge, is a high boiling petroleum naphtha, distilling within the range 360 to 420 degs. F., which corresponds to the first 60 to 70% over in the fractionation of "standard waterwhite kerosene." This material serves not only as the most economical heating medium, but owing to the high temperature maintained in the desiccating mass, serves to remove or dissolve the metallic soaps as well as the free grease.

Cold, or merely warm, solvents of a less oily nature have little solvent action on such soaps, but high boiling oils, particularly when carrying small quantities of grease, are able to dissolve them without difficulty. Upon cooling they are apt to be deposited as jelly-like masses or to cause the gelatinization of the whole solvent solution, and for that reason the solution must be treated, before entering recovery stills, in such a manner that the soaps are decomposed and a solution of clean fatty acids result. This treatment will be taken up in order.

Description of Apparatus

The following is a brief description of apparatus and the method of carrying out the operation:—

The principal apparatus consists essentially of a closed tank, circular in shape and of a diameter three times the height. Jackets are provided on the bottom and well up the sides, so that as much available heating surface is obtained as is possible. Through the bottom, oblong screened openings are provided for the withdrawal of solvent and grease, and for the pumping in of solvent during the cooking or desiccating operation.

Within the tank proper is a central shaft, provided with two sweeps set very close to the bottom in such a manner that they shall slide under the mass to be treated, imparting an undulatory motion, without cutting through the mass itself. For this reason very little power is required. The tanks are of shallow form in order that the amount of heating surface in proportion to the mass to be treated may be as great as possible. Greater height and capacity could only be obtained at the expense of operating time and greater consumption of power. The top of the tank is provided with charging manhole and outlet pipe to condenser for vapors.

After the tank is loaded with sludge, the charging manhole is securely closed by the swing cover, solvent is admitted through the bottom screens, sufficient to immerse totally the mass of sludge, and steam turned on jackets.

Combined vapors of solvent and water vapor pass out through vapor line to surface condensers of suitable capacity, and in these the mixture of solvent and water vapor is condensed to liquid, which, leaving the tail pipe of the condenser, passes to separating tank, where by virtue of the lighter gravity of the solvent, separation of solvent and water is effected. The solvent flows to storage for re-use. Owing to rapid evaporation, the solvent level is lowered in the tank and a further quantity is pumped in.

Four to five hours are required for the evaporation of all of the water, and at this time, through the sight glasses, the dried fibre, etc., can be observed floating on the top of the solvent. At this point the agitator is stopped, the steam turned off, the drain valves opened, and the grease-laden solvent pumped out through a solvent out-pump line. Several washes with fresh solvent complete the degreasing of the mass, which is then heated, agitated and (with the help of live steam) freed from the absorbed solvent left in the mass after draining.

Preliminary Treatment

Solvent carrying with it the extracted grease, soaps, etc., must receive preliminary treatment before passing to the solvent-recovery and grease-finishing stills. This treatment is carried out in a lead-lined tank provided with an agitator. To the solvent is added a sufficient quantity of sulphuric or muriatic acid and water to completely decompose the metallic soaps present. The acid water is well churned up with the solvent, allowed to settle and drained off; fresh water is added and mixed, allowed to settle and the clear grease-solvent solution run to the recovery stills.

By this treatment, foaming and other difficulties are avoided in the distillation, and the grease recovered does not form the difficultly separated emulsions it is disposed to do. Such grease can be cleaned up and settled free from mechanical impurities and moisture without undue trouble.

The entire cycle of operations takes place in a closed circuit, and the only vent for non-condensable gases for the whole system of tanks (or reducers), condensers, separating tanks, washers, stills and storage tanks, is on the final solvent storage tank or tanks. This vent in turn exhausts through an oil scrubber to recover traces of naphtha carried over by carburetting. During no period of the operation is the sludge exposed to the air or manhandled in any way, until it is finally discharged from the side-door of the tank in a dried, degreased condition. The only places where odors or noxious effluent is exposed to the air and liable to cause an unsanitary and nuisance condition, are at the gas vents on the storage tanks and at the effluent overflow on the separating tank.

This effluent is, of course, distilled water from the sludge, and carries with it the odor of the sludge, which in the case of fresh sludge and that preferably handled, is very offensive. The quantity of this water is of course equal to that contained in the sludge prior to desiccation and the condensed steam from the steaming out of the solvent from the drained sludge prior to dumping from machine. This approximates a ton of effluent for every ton of sludge handled.

Deodorizing Effluent by Chlorination

The only way found by the writer to effect deodorization of this effluent and to render it harmless is by the addition of chlorinated lime or chlorine water. The greatest amount necessary for deodorizing very foul water is one part of 35% available chlorine bleaching powder to 3,000 parts effluent. The non-condensable gases leaving the storage tank vents must be scrubbed with chlorinated lime solution before being allowed to pass to atmosphere.

With these precautions, it is safe to say that the entire operation of desiccation and degreasing, or the whole recovery operation, can be carried out with no offense to public welfare and sanitation.

In handling sewage sludge by this method, no difficulties have arisen, other than those usually met with in handling wet organic materials of other sorts, and since in sludge the moisture is present in free condition, mechanically combined, the period required for desiccation is much shorter than that met with in the treatment of garbage and animal refuse, in which the majority of the water is more or less chemically combined. For this reason only four or five hours are required in drying a given amount of sludge, compared with at least twice that for same amount of garbage.

Capacity and Cost

Experiments and trial runs indicate the capacity of each tank as 8 tons in 24 hrs., and in a plant handling the sludge from a town of 200,000 inhabitants (approximately 40 tons daily, 75% moisture basis) the cost for handling, including overhead and fixed charges, will approach $6 to $6.50 per ton on green sludge.

This cost will not be greatly changed in handling sludge containing 65% or 50% moisture, but since the gross tonnage to be handled would be greatly reduced, the plant investment would be greatly reduced, and the by-product returns per green ton much greater. If by any method of dewatering on beds or other inexpensive method, the moisture can be reduced below 75%, by just so much will the success of a recovery plant pass from just self-maintenance to a possible profit.

After carrying out such an operation, what possible yield of by-products may be expected, and what is their character and what their value? This depends entirely on the nature of the sewage handled. It has been presupposed that any sludge running less than 3% of ammonia on a dry tankage basis is not worth handling, unless indeed the grease content is very high, in which case it is possible that the grease alone might pay for recovery.

From an average of a number of analyses, however, it would seem as if a sludge low in ammonia is also low in grease, so that a 3% ammonia tankage would indicate a 15 to 25% grease content on a dry basis. For these reasons, in handling a 75% moisture sludge, a yield of 420 lbs. of tankage and 75 lbs. of grease may be expected.

Market "Value" of Grease

What is the nature of this grease and tankage? Have they any market value? What use is it to rescue this material if it cannot be sold or used? This is not a matter to be dismissed offhand. At the present time, if either or both of these products were thrown on the market, emphatically they would not find a purchaser, or certainly the price would be absurdly low. Consider the nature of these by-products as indicated by their analyses:—

Analyses of Greases From Different Types of Sludge

	Free fatty acid.	Unsaponifiable.	Neutral.	Dirt and moisture.
Baltimore (acidulated),	77.48%	11.78%	.....	10.74%
Chicago (activated), ..	48.80%	24.40%	19.10%	7.70%
Syracuse (sedimentation),	51.50%	19.30%	18.70%	10.50%
Pleasantville, N.Y. (sedimentation), ...	75.70%	19.80%	4.50%	.....

Boston, Moon island (sedimentation):—

Free fatty acid (as oleic), ...	48.40%
Free fatty acid (by weight), ...	40.19%
Rosin acids (in fatty acid), ...	14.36%
Fatty acids (by difference), ...	25.83%
Unsaponifiable, ...	21.09%
Neutral grease (by weight), (molecular weight of neutral fatty acids, 272), ...	20.00%
Metallic soaps and solid impurities, ...	3.30%

The first four analyses are of grease recovered in the process outlined, and it will be noticed that in the first three, large quantities of solid impurities and moisture are recorded. All grease of sewage sludge origin on leaving stills contains large amounts of such impurities, since due to the emulsifying action of the waxes present in the so-called unsaponifiable, it is very difficult to obtain clean greases without subsequent washing with acid and settling. The fourth analysis is of a grease after such treatment.

These analyses are of several different types of sludge and sewage treatment, yet all present the following general characteristics:—

The saponifiable matter in each case consists for the most part of free fatty acids and a very small portion of neutral grease or combined glycerines. This is, of course, anticipated by the fact that the greater part of the grease present in sewage sludge comes from hydrolyzed soap solutions, or through the action of bacteria and ferments, neutral grease has been broken down into fatty acids and glycerine. In any event, the neutral grease present gives no hope of glycerine recovery, so at once the so-called grease falls into the grade of poor-class fatty acid stock. Of the total fatty acids present in a number of analyses, from 1 to 15% of the total consist of rosin acids. These again are from the soap solutions.

The unsaponifiable matter varies from 10 to 30%, but a majority of samples analysed show an average of 20%. As may be supposed, the lowest percentages are found in strictly domestic sewages, where they are traceable to body waxes and products of physiological action. In mixed sewage from manufacturing towns, the unsaponifiable is highest, as it is made up of mineral oils thrown out from different factories, wells, etc.

A small percentage of metallic soaps of calcium, iron, aluminum and magnesium are present, but upon proper treatment are broken down into fatty acids and mineral salts, washed out as sulphates or chlorides (depending upon the sort of acid used for refining).

Very Low-Grade Material

From these premises it is necessary to conclude that sewage grease can be regarded only as a very low-grade fatty acid stock containing 70 to 75% of fatty acids and 25 to 30% of unsaponifiable. These fatty acids, depending on the sewage from which they are extracted, will vary in color from a dark ruby red to a black, tarry-looking mass. In consistency the variation is between a soft, buttery mass and a hard, solid cake. This is quite readily explained; the former is very high in fluid mineral and industrial refuse oils, the latter from domestic sewage in which the high-melting-point fatty acids have been hydrolyzed and precipitated from the soap liquors, whereas the oleic-acid soaps or oleic acid present in mixed soaps, remain in solution and pass off with the effluent.

Fatty acids of this type have no legitimate market at this time. Such materials are only valuable as they are refined and made into marketable products. A purchaser of sewage grease would have to expect by his own efforts to give it all of the value it might ultimately have, and having created something out of nothing, he would care to pay little for the raw material. That sewage grease in refined or manufactured form has value is not to be questioned. Such a grease as that indicated by the analyses of Pleasantville sludge grease, upon distillation in the manner usually employed for fatty acids, gave the following yields:—

Light colored distillate,	85%
Still returns,	6%
Stearine pitch,	6%
Loss,	3%

The distillate was orange yellow in color and of high titre, and upon pressing gave 50% of good colored stearic acid of titre 53.3C., and 50% of red oil containing 38.25% unsaponifiable. Upon pressing, all unsaponifiable matter passes out of seeded or crystalline cake in the red oil, leaving good stearic acid behind. This red oil is marketable for grease-compounding and as wool oil. In other words, sewage grease must be manufactured to have value. Once its value is established, a market will be automatically created for the raw grease.

Shall Municipalities Combine Efforts?

Upon whom shall the burden of carrying out these operations fall? Shall each sewage plant carry out the whole work from sewage to finished product? Shall a number of sewage plants pool their sludge, or their raw grease and tankage, and finish at a central plant, or shall a number of plants interest directly a corporation or individual able to carry out the refining operation? At this point sewage sludge ceases to be a problem for the scientist and becomes a purely business proposition.

Returning to the question of disposition of the tankage, it would require considerable propaganda to place upon the fertilizer-goods market a low-grade 3% ammoniate, cursed with the name sewage sludge, though in the old days of poudrette it had an enhanced value in the public mind far greater than its chemical value indicated. The great diluent of sewage tankage is insoluble ash or mineral matter, running from 40 to 70%, with 60% as an average. It is not impossible to concentrate this, though methods are not yet complete for doing so. A number of experiments conducted by the University of California indicate that for percentage of nitrogen contained, degreased sludge has higher plant-food value than that in dried blood or high-grade tankage.

Even with reasonable markets for the tankage and grease, it is a question whether it is possible to recover enough materials to defray the cost of the operation. In the opinion of the writer, and from experience in the garbage-reduction business, it does not seem impossible, though there would be little margin of profit left. But the sludge would be disposed of, its disposition paid for and a large amount of needed materials returned to active use, assisting in helping out the world's supply of chemicals and greases. The individual city would receive no monetary return, probably, but virtually to create actual concrete products of economic value, to pay for the creation and at the same time solve a troublesome disposition problem, is something well worthy of consideration.

With ordinary sedimentation of suspended solids, it is not at all unreasonable to expect from the sewage of a town of 150,000 people, daily recoveries of 5 tons of tankage and 1 ton of grease. There are many towns of this size. Any city of this class which can return to a useful cycle $50,000 worth of needed materials annually should consider well the disposition of its sludge pile.

Solving the problem of sludge disposition is not impossible, but it is difficult. No chemist, engineer, business man or politician can solve it alone. That co-operation which has not existed must first be accomplished before there may be any hope of solution.

Approximately 100 miles of road have been resurfaced this year in Elgin County, Ont., and eight culverts and two bridges have been built. The total expenditure on construction, maintenance and overhead has amounted to about $140,000.

Four by-laws have been passed in Calgary, voting $350,000 for a sewage disposal plant; $278,316 for extensions to the waterworks system; $155,978 to be added to a sum previously voted for building a concrete bridge to replace the Louis bridge over the Bow river; and $155,000 for a fireproof addition to the hospital.

Hon. Peter J. Veniot, minister of public works in the New Brunswick government, speaking at St. John, N.B., stated that New Brupnswick, of all provinces in Canada, is the only one that constructs and maintains its roads entirely from provincial funds. In the past three years, the sum of $2,125,000 has been spent on public roads, and it is hoped that during the next ten or fifteen years it will be possible to repair and maintain in good condition all the 17,000 miles of main trunk roads in the province.

With the intention of supplying Halifax with 7,800 h.p. at an estimated cost of $1,200,000, the Nova Scotia Power Commission has been authorized to proceed with the development of the water powers at St. Margaret's bay. The preliminary plans call for the establishment of storage dams at various points on the Northeast and Indian rivers. The water of the Northeast river will be collected by a head dam at Coon pond, and thence directed by a flume to a power-house at the head of Mill lake, where a head of 160 ft. will be obtained. The water of the Indian river, collected at a head dam at the foot of Sandy lake, will be directed to the same power-house, giving a head of 100 ft. A third flume will conduct the water from this power-house to a second power-house, which is to be established at tidewater, where the head is 90 ft. The power will be transmitted to Halifax on a wooden pole transmission line, 20 miles long.

ESSEX BORDER WATER WORKS

DESIRING to consolidate the existing water systems within the district, the Essex Border Utilities Commission has adopted a report which has been presented by Morris Knowles, Ltd., consulting engineers, Windsor, Ont., and will soon ask the people of the Border Cities to vote upon the scheme.

In the engineers' report, provision is made for five years' development of the water supply systems of the border municipalities, whereby the present generally unsatisfactory conditions of supply in the district will be relieved, and new territory which is not now supplied with water will be made available.

An approximate valuation of the Windsor water works, the Walkerville Water Co.'s distribution system and existing pipe lines in Ford City, Sandwich, Sandwich East and Sandwich West, totals $950,000, and an approximate fair compensation to Hiram Walker's Sons, Ltd., for pumping equipment is estimated by the engineers at $30,000. It is recommended that these systems be consolidated under the commission's direction by assuming the indebtedness now carried by the various systems and by issuing debentures to the various corporations for the remaining value.

The first year's program of improvement to the existing system includes the extension of a pipe line from Windsor to and through Sandwich to form a complete loop, at a cost of $95,000, and the arrangement of a site for consolidated supply and purification works, at a cost of $200,000.

During the second year it is proposed to start the construction of the consolidated works and filter plant, at an estimated expenditure of $250,000, and to connect with the Windsor distribution system by means of a 36-in. main, at a cost of $185,000. This would give a much better distribution system, and as soon as the pumps are ready to operate, would provide, by means of the extensions recommended for the first year, a much improved domestic and fire service for Ford City, Walkerville, Windsor and Sandwich.

Further extension of the distribution system in Windsor and Walkerville is contemplated for the third year, and is estimated to cost $105,000. The construction of the pumping station and filter plant would also be completed at a further cost of $225,000.

For the purpose of reinforcing the distribution system in Windsor, and giving much needed fire protection in the business area, several 12-in. mains would be laid during the fourth and fifth years. The distribution system would be extended from Sandwich to Sandwich West and Ojibway, further reinforcing mains in Sandwich bringing the total expenditure for these years to $220,000, and making a grand total, for the five-years' development, of $1,130,000.

By acquiring the Windsor pumping station and taking over the pumping equipment of Hiram Walker's Sons, Ltd., it would be possible to utilize in the consolidated pumping station the pumps which have been recently purchased by the Windsor Water Commission and also the newer steam pupms in both the Windsor and Hiram Walker stations.

The Bureau of Municipal Research has issued a bulletin on "Forms of City Government," which says:—"To overcome some of the drawbacks of the mayor-council-board-of-control plan, the formation of an administrative board, made up of the heads of the various civic departments, with one of their number as chairman, has been suggested. This could be tried by any city, without change from the present system, simply by directing the heads of departments to meet once a week for discussion of administrative policies and the taking of joint action wherever possible without special legislative enactment. A mayor, council and board of control could be elected on the plan at present in use, council retaining its legislative and policy-deciding functions. Later, if the working of the board was successful, provisional legislation could be obtained to enable it to undertake the work now done by the board of control. The city council could then keep in touch with the departmental administration through a small executive committee appointed from their number to act with the administrative board."

REGULATIONS UNDER CANADA HIGHWAYS ACT

Order-in-Council States Method of Making Application for Federal Aid and Gives Information Regarding the Proposed Administration of the Act

SECTION five of the Canada Highways Act, which was passed last July by the Dominion parliament and which will be administered by A. W. Campbell, commissioner of highways, states that the governor in council may make such regulations as are deemed advisable for giving effect to the objects and purposes of the Act, which appropriates $20,000,000 to encourage the provinces in the construction or improvement of highways. In the December 13th issue of the "Canada Gazette," the official medium for notices of government rulings, notice is given of the adoption by order-in-council of the following regulations under the above-mentioned Act:—

"Sec. 5—The governor in council may make such regulations to be published in the 'Canada Gazette' as are deemed advisable for giving effect to the objects and purposes of this Act."

Work to be Aided

1. The highways to be aided under the Act shall comprise such main and market roads as have been designated by the province as hereinafter provided with a view to encouraging production and stimulating trade and commerce, and as shall be approved by the minster.

To Supplement Customary Expenditure

2. It is understood that the expenditures called for under the Canada Highways Act are intended to supplement the usual amounts granted and devoted to the construction and improvement of its highways by the province itself.

Method of Making Application

3. Before an agreement is made with respect to any road or roads, there shall be furnished to the minister by the provincial government a statement setting forth a programme for construction or improvement of a system of highways in the province, from which projects shall be selected. Such statement shall be accompanied by a general map of the proposed program, bearing the approval of the provincial government and the endorsement of the highways department thereof. Each provincial program shall include, first, roads having greatest local agricultural and commerical importance; and second, roads having both local and general importance, and these programmes shall be so adjusted and arranged that the whole shall be correlated and form, as far as possible, a general system of interprovincial highways. This program and amendments thereto shall be satisfactory to the minister, and applications relating to the construction of specific portions thereof shall be made from time to time as provided for in the following section:—

Plans, Specifications, Estimates, etc.

4. Each application for aid shall be embodied in a project statement, on forms which may be had on application to the commissioner of highways of the department of railways and canals, which shall contain the following information and exhibits:—

(*a*) The purposes the undertaking will serve, and why it is in the public interest;

(*b*) The character and extent of traffic, present and prospective, on the road;

(*c*) How the undertaking relates to the provincial program;

(*d*) A statement of the type of construction or improvement it is proposed to make, together with a report of the engineer of the provincial highways department endorsing the adoption of the proposed type and the design thereof as being the most economical and practicable in the public interest, his reasons therefor, and a full explanation of any special or unusual features thereof;

(*e*) The administrative control of and responsibility for the undertaking;

(*f*) The source and method of procuring the necessary money for the underaking and the extent to which interested municipalities contribute thereto;

(*g*) Plans in standard form to be prescribed by the minister and in detail following accepted engineering practice, together with a sketch map showing the position of the proposed project on the general program map of the province;

(*h*) Specifications in standard form to be prescribed by the minister setting forth the proposed type and method of construction, materials to be used, and other essentials, in such detail as to afford complete knowledge of all steps to be taken in carrying out the project;

(*i*) Copies of the form of contract to be used, together with all documents referred to therein or made a part thereof; and

(*j*) Estimated cost of the project, giving a schedule of quantities and the estimated cost of each item in detail.

All project statements, plans, specifications, estimates and other papers required in connection with any application of a province for aid under the Act shall be forwarded to the commissioner.

The Agreement

5. When a project statement has been approved by the minister an agreement, as provided for in the Act, between the province and the minister shall be executed in triplicate by the province on a form furnished by the commissioner.

No payment under the Act shall be made until such agreement has been executed by the minister, nor shall payment be made for work done prior to such execution unless with the express approval of the governor in council, which approval shall not be given in connection with work done prior to the coming into force of the Canada Highways Act or not done in accordance with these regulations.

Tenders and Contracts

6. All expenditures shall be made pursuant to tender and contract, except as provided by the Act, and shall be on the basis of unit prices. Tenders shall be called for at least three weeks before the work is to be let, and notice of the calling for tenders shall appear in a contractors' or engineering journal as well as in such local newspapers as the province deems necessary.

Payments

7. In determining the actual necessary and reasonable cost of any highway for the purpose of fixing the amount to be paid under the Act, the cost of the following shall not be considered as a part thereof:—

The cost of right-of-way and incidental damages, bridges, viaducts, subways, exceptional grade separation, provincial overhead and administrative expenses, the making of surveys, plans, specifications and estimates, or any engineering expenses incident to the project prior to the beginning of actual construction. The cost of culverts having a clear width of opening of not more than twenty feet may be included.

Certified vouchers showing the amounts expended on each section of completed road, also showing the amount, if any, expended on any uncompleted section up to sub-grade at the termination of each fiscal year during the five-year period commencing April 1st, 1919, shall be submitted to the commissioner; and when he has certified that the terms and conditions of the agreement, in respect of the plans and specifications annexed thereto have been carried out as far as relates to such sections, forty per cent. of the cost thereof as defined by these regulations, and expressly subject to section five thereof, will, upon authority of the minister, be paid to the provincial treasurer, or other person named in the agreement to receive the same.

Records

8. Such records of the tenders submitted of the cost of the work, of the inspections made and tests of materials shall be kept by the province as shall enable the commissioner at any time to determine the cost to the province and the status of the construction work done on any project. These accounts and records, together with all supporting documents, shall be open at all times to the inspection of the commissioner or his representative, and certified copies thereof shall be furnished at his request.

Inspection

9. The supervision of each project by the provincial highway department shall include adequate inspection of work and material by competent engineers throughout the course of construction. To this end, any recommendation of the minister to the provincial government with respect to the necessary technical qualifications and experience of the members of the highway organization will be enforced by such government.

Maintenance

10. Each province shall agree that when the roads or highways constructed or improved with Federal aid shall have been accepted as completed, the province shall maintain, or cause the same to be maintained, with all necessary repairs and renewals, so as to preserve the standard of construction of each particular class of completed road or highway.

CONFERENCE ON CONCRETE HOUSES

FROM February 17th to 19th there will be held at the Auditorium Hotel, Chicago, a National Conference on Concrete House Construction. The purpose of the conference is two-fold: (1) To consider the housing problem in the United States and Canada; and (2) to present, crystallize and make available, information regarding the most modern practice in the construction of concrete houses.

The following committees are now being organized: Architecture and design, community planning, financing permanent homes, fire prevention and insurance rates, building codes, monolithic concrete houses, special unit houses, concrete block houses and concrete and cement roofing.

Among the organizations co-operating in this conference are the American Concrete Institute, the Associated General Contractors of America, the Concrete Products Association, the Portland Cement Association, the Illinois Society of Architects, the Illinois Chapter of the American Institute of Architects, and the U.S. League of Building and Loan Associations.

During the week of the conference on house construction, there will also meet at the Auditorium Hotel the American Concrete Institute, the Concrete Products Association, the Concrete Block Machinery Association and the American Concrete Pipe Association.

Work has been completed on the installation of the hydro-electric power plant at Squamish, B.C., the tidewater terminus of the Pacific Great Eastern Railway, and the plant will be "turned over" this month. The project involved the construction of a dam in the Stuwamus river. The cost of the development was about $90,000.

Premier Drury, of Ontario, outlining the road policy of his administration, said that it is the people of the little towns and rural districts who need good roads the most, and that there is great need for market roads throughout the province. It had been argued, he said, that the revenue from motor cars should be expended on main highways. He held that part, at least, of this revenue should be used on roads serving the greater body of people. His highway policy would include these three things, he said: (1) The abandonment of the construction of expensive trunk highways, retaining the roads already built and probably improving them and making them all into "decent-running roads;" (2) spreading out the provincial roads where they will do the "greatest good to the greatest number," spending the money available on the whole road system and giving aid to country roads; and (3) giving assistance to township roads.

WHY QUEBEC MUNICIPALITIES SHOULD HAVE CLEARING HOUSE FOR INFORMATION*

By Charles A. Mullen
Director of Paving Dept., Milton Hersey Co., Montreal

THE broad objects of the Union of Quebec Municipalities, briefly stated, are to secure voluntary co-operation among the member cities, for the support and collective municipal ownership of a public organization to act as a clearing house for information and as a central bureau through which two or more cities, when they so desire, can combine for the purpose of securing from the province legislation which in is their interest, and for any other matter wherein it is thought two or more cities, acting together, can get better results than if they acted separately.

A service that could be organized quickly, and which would at once begin to pay dividends in savings effected by the several municipalities, is a central bureau which could be used for purchasing many items of supplies. This service would not abolish any separate municipal purchasing bureaus now in existence, but would be rather a super-bureau, requiring a well-organized system of purchases in each member city, for its proper working.

Central Purchasing Bureau

Why have the purchasing officials of many cities getting data and prices on general equipment they all use, when it can all be done by one man; and why not buy collectively whenever it is possible to do better that way? The organization of proper purchasing systems for its member cities would in itself be a suitable field of activity for this Union, and one good man, who would by study and experience become particularly proficient, could be handed around from city to city.

Through a central organization, each municipality will be better able to look its latest "gift horse" in the mouth, for the collective transactions of all the cities in any one article which is offered in the municipal market will be of sufficient moment to warrant the spending of a little money on investigation and study.

In no line, I think, is this more true than in my own; for were a careful engineering report secured by such a Union as this upon certain pavements which are being laid, and copies submitted to the various member cities, I think that pavement promoters would grow less fat and municipalities go less into debt and occasionally into a state which approaches bankruptcy.

Such a bureau, be it purchasing or any other, should have as its board of directors the purchasing or other interested officials of its member cities, and the super-purchasing agent should be their employee,—not their boss. Much greater efficiency, in many cases, comes from the bottom up, and I am inclined to think that the success of the Union of Quebec Municipalities is largely going to depend upon whether or not those entrusted wits its launching will properly understand this principle and use their best energies in setting it to work. These are not days to talk of abandoning the principle of Home Rule for cities, even for the purpose of forming a municipal union. One ounce of voluntary effort is worth a pound of forced co-operation.

"Engineering Profession Principally Involved"

One great value the Union will have for its member municipalities will be in supplying them with reliable information and advice when they have to deal with professionals, especially from out of town; and here the engineering profession, of which I am a member, is principally involved, though the lawyers and the doctors also come in for their share of municipal work.

It may be true that when the Union attempts to handle engineering matters for the member cities, if great care is not exercised, there will be a slight danger of injustice to some of the profession; but I do not think this danger is to be compared to that which the cities encounter when they go out, unaided, to seek engineering or other professional advice and services. High-class engineers are frequently not nearly so good at selling their wares as some other engineers who would do the country much less harm as commercial travellers.

There are, as we all well know, shysters in all the trades and professions to-day, for our present social system seems to encourage and reward their efforts in many directions. Under the plan of co-operative administration I have already outlined, where the engineering bureau would be in the hands of the engineers—subject, of course, to the general administration—it seems to me that the shyster would have a much less rosy path than he has to-day.

Says "Canadian Engineer" Mistaken

The Canadian Engineer of October 23rd, in its editorial column, shows grave concern about what it thinks the Quebec municipalities are about to do; but I am sure its attitude is based on a misconception of the plan. To me, it seems that more and not less professional services will be employed because of the existence of this Union. Cities will learn from their own representatives at headquarters, whom they will have reason to trust, just when and to what extent professional services are a good investment for them. To-day, they do not know, and have not a sufficiently unbiased and trustworthy source of information; and they frequently go without rather than risk employing some shyster.

I am quite sure that it was also a misunderstanding which led *The Canadian Engineer* to remark about the doubtful value of "free" engineering or other professional services. The Union will be paid by its supporting member municipalities through memberships, as far as its general work is concerned; and each city will probably pay extra for special services rendered. We have never heard the engineers complain when several private corporations formed a union or trust and amalgamated their engineering staffs, and such combinations are far more destructive of individual initiative and competition among engineers than the Union of Quebec Municipalities could ever hope to be.

Impugns One Firm's Integrity

One good which the engineering profession should get out of the formation of this Union is the better application of the energies of its members.

I have one particular case in mind where a firm of engineers undertook a piece of work in which they certainly were not specialists. The contract was let; and, not having an intimate knowledge of the subject, these engineers left it to the contractor to do the work in accordance with his own theories, which happened not only to be based on a limited experience and wrong, but were known by all specialists in that line to be wrong. The work, after one year, now shows signs of failure. It is bad enough to have to follow defective principles when it is not possible to follow the correct ones; it is inexcusable to do so through ignorance of those principles which have been proven correct in practice, and are generally accepted among the specialists in that field of engineering.

The leading member of the engineering firm referred to above, whose name professional courtesy prevents me from mentioning, at the time this work was being done in accordance with wrong practice (because to insure correct practice they would either have had to call in specialists and pay them out of their own very liberal fee or not attempt the work) said to me:—

"We never take a chance. If we are building a wall, we figure the usual factor of safety required by good engineering practice, and then add at least 20%. Our work is a monument to us, and our reputation is the very highest."

Yes,—building monuments to the reputation of their firm by the unjustified expenditure of public money, which expenditure also increased their percentage fee. The cities are, to-day, almost helpless before such engineering malpractice; in fact, on the part of unscrupulous engineers, it is an excellent way to acquire a very fine appearing though falsified reputation which will bring more business. The point in this instance is that this firm was willing to take all sorts

*Excerpta from paper read at the organization meeting of the Union of Quebec Municipalities, at Montreal, Que., December 16th, 1919.

of chances with their reputation to save themselves a few extra dollars, but was perfectly willing to buy the best reputation at any cost whatever with city money. One good engineer on the bureau staff, keeping in touch with the field, would soon detect and expose such malpractices as these.

Many cities are to-day repating the mistakes made by other cities, and thereby learning through their own costly experience what they might much more cheaply know from the dearly bought experience of other municipalities. I have in mind one city in particular which is now going ahead with a certain type of paving work which was tried out and abandoned in other places many years ago. It thinks it has discovered something new.

Suggests Visiting Engineering Specialists

What we need is a clearing house for knowledge and experience, where a city may inquire about what has been done elsewhere and what were the results. The Union of Quebec Municipalities promises to furnish such a clearing house for this province, and I believe the results will be most gratifying. A step still further would be advisable; and it may be practical at some future date to have a staff of visiting engineering specialists go around and see what the cities are doing in the way of following wrong practices without even suspecting it themselves.

Another service that may be facilitated by the union is the exchange of expert operators between the different cities. This fall, the city of Charlottetown, Prince Edward Island, which has installed a municipal asphalt plant, needed some expert laborers for operation. We appealed to Mr. Doucet, the director of public works, and to Mr. Blanchard, his engineer of roads, of the city of Montreal, and they were glad to go out of their way to accommodate a small city in a sister province. Montreal men went to Charlottetown, and did their work so well that Charlottetown now knows what kind of a public works department Montreal has. What was arranged in this case would be done much more frequently between cities who are members of the same union.

All of the foregoing shows very clearly the need of the bureau or clearing house for information which it is proposed to establish in connection with this union. Not only can the experience of one Quebec city be made available, in fact be reported to all the other Quebec cities, but, if the organization falls into very active hands, much valuable information can be secured from the outside municipalities and supplied to the proper official in each of the Quebec municipalities. Such a bureau need not wait until it is requested for information which some city finds it needs; it can go out into the highways and byways and seek out information which will be of benefit to its member cities but of which they do not happen to have even heard.

While we do not all want to be alike, economy and efficiency certainly demand that we do be alike in most things where there is no good reason, practical or artistic, for being different. Some advantage will accrue from a sort of interchangeability of parts, even to municipalities; and I think much can be done by this union towards a sane amount of standardization.

Standardization of Municipal Equipment

If three cities are using different models of a given machine which each is building or buying, why should not the representatives of these three cities get together, decide, if they can, which machine is the best, or possibly design a new one which will be a composite of the three and superior to all, and adopt that as a standard until something new develops? The street railways of North America have standardized the rails they use, for instance; and it is standardization like this which I have in mind. Such standardization might also be made to operate in favor of Canadian manufacturers, whenever possible, without appreciable loss to the cities.

Just now, the commission-manager form of government, with proportional representation, has the centre of the municipal stage. My study of the subject finds me very much in favor of this type of machinery for city government; but I would very much like to know what a committee appointed by the Union of Quebec Municipalities, from among their own members, would say about it. After careful study, this committee would either recommend this type of commission-manager charter for Quebec municipalities, would offer some improvement upon or amendment thereof, or would reject it as not so satisfactory for Quebec as the present type of charters. At least, we would get action upon such a matter; and it would not be left for a few public-spirited men to spend their lives going from one city to another recommending this change.

There are, of course, a certain number of persons and interests in every community who prefer things-as-they-are. Some of these folk are just too lazy to move in a new direction; others are securing special privileges under the present order and fear they may lose them during the change. There are a certain number of business firms selling to cities, a certain number of contractors doing business with cities, who do not want any bureau of information which may tell their customer cities how badly they are being over-reached. The job holders who do not want any new-fangled ideas which will mean more work may also be relied upon to speak against any such innovation as a municipal union which means business; but I am confident that most municipal employees will respond to the call for more efficient organization with alacrity.

As far as the firm of which I am a member is concerned, we believe the formation of this union can produce nothing but good for us, for we think it will mean a greater appreciation on the part of the member municipalities of the value of the kind of work we do. Moreover, if the day ever comes when the union thinks it necessary to municipalize us, or any part of us, and a workable plan is forthcoming, there will be no opposition on my part. I believe in municipal ownership up to the hilt; a municipally owned municipal league and all that may logically grow out of it.

Representatives of the Dominion and Manitoba governments conferred last week with delegates from the United States, who visited Winnipeg, on the problem of prevention of floods in the Red river valley. Large areas of Manitoba, Minnesota and North Dakota are flooded every spring from that river's overflow, and seeding operations are delayed. Schemes were suggested which the United States representatives declared would mean a saving of $100,000,000 during the next thirty years.

J. G. Sullivan, formerly chief engineer for the C.P.R.; J. C. Holden, C.P.R. district engineer; B. Stewart McKenzie, consulting engineer; and W. P. Brereton, city engineer, all of Winnipeg, Man., have advised the Greater Winnipeg Water Board that in order to prevent gradual disintegration of the Shoal lake aqueduct, it is necessary to underdrain the section in which the conduit is exposed to the action of water heavily charged with alkali. John Woodman, consulting engineer, disagreed and gave his opinion that the aqueduct is quite safe from alkali action. The engineers had been called in by the board to express their opinions as to what should be done in connection with an underdrainage scheme submitted by Chief Engineer Chace and which will involve an expenditure of from $300,000 to $400,000.

Speaking at the evening session of the United Farmers' convention, December 17th, at Massey Hall, Toronto, Hon. Mr. Biggs, Ontario minister of public works, said that the government proposes to abolish statute labor. He suggested aid for township roads, using the revenue received from auto licenses for this purpose, and giving special consideration to the poorer townships which are not in a position to help themselves, by setting aside $2,000,000 for loans to them, repayable in five-years without interest. Mr. Biggs stated that the federal government has allotted $6,000,000 to the province of Ontario for provincial highways, and he thought that the Ontario government should avail itself of the full amount and "construct 1,600 miles of provincial county roads." "I would say," he continued, "that we do not intend to build any hard-surface roads at any place, unless the cost of building them is less than a macadam road."

HAPPY NEW YEAR!

NEXT Thursday will be the happiest New Year's Day that Canada has experienced in half a decade. That the war has been conclusively settled is now beyond doubt, and equally certain is it that the troubles of the reconstruction period are being rapidly overcome. The new year will be a very busy one in engineering circles. There will undoubtedly be satisfactory employment for every engineer and plenty of profitable business for all engineering firms. Let's go! Let's produce! Make the wheels hum in 1920! Happy New Year!

MORE FLUSHING, LESS DISEASE

WHEN suddenly enveloped in a whirling cloud of dust from dirty, unflushed pavements, we encounter a positive danger almost as deadly in its possibilities as a gas attack. What we are possibly too accustomed to regard as an unavoidable annoyance has been demonstrated by scientists to be one of the gravest causes of some of the most deadly diseases that affect mankind,—those of the respiratory organs.

Pneumonia alone has an enormous yearly death-rate in this country. The fact that pneumonia germs can live for a considerable time in dust is well known, but apparently little thought has been given to the extreme danger of communicating this disease by means of the dust thus infected. Dr. Rufus Cole, of the Rockefeller Institute, says: "We have been so interested in better water supplies, better sewerage systems, etc., that we have forgotten the importance of dust in spreading infection, especially in spreading the acute respiratory diseases which now cause more deaths than all the other acute communicable diseases combined."

This reminder is a good one for all municipal engineers and street superintendents to ponder, for it is to them that the public must look for adequate protection from the dangers of unlaid dust. Typhoid has been practically conquered by municipal engineers; they should now give earnest attention to the dust evil, and, by making arrangements for thorough flushing, add one more to their long list of public benefactions.

SALARY SCHEDULE FOR HIGHWAY ENGINEERS

AT the convention of the American Association of State Highway Officials, held this month in Louisville, Ky., a resolution was passed endorsing a list of recommended salaries for engineers in state highway service. This list had been prepared by a committee of the American Association of Engineers.

A. N. Johnson, consulting highway engineer of the Portland Cement Association, who was chairman of the American Association's committee, in addressing the convention stated that the recommended salaries had been established by first selecting three places in the schedule: The highest, the middle position, and the lowest.

The highest position was that of the chief engineer of the state highway department. The middle position was "considered to be one requiring an engineer having at least four or five years' experience since graduation from college,—a man who, it may be expected, will be married. Such a position should, therefore, carry with it a salary to enable a young engineer with a small family to live in comfortable and appropriate surroundings. The lowest position was established as one filled by a recent graduate.

"The salaries established for these three positions are $8,000 to $15,000 for the highest; $3,600 to $5,000 for the middle position; and $1,200 to $1,500 for the lowest.

"If practical results are to follow suggestions regarding salaries of engineers in public service or in any other service," said Mr. Johnson, "the first essential is unity of opinion and purpose amongst engineers themselves. One of the chief drawbacks to higher salaries for engineers in public service has been, in the past, the opposition of these very engineers themselves. This may seem at first paradoxical, but here is an instance: A legislative committee gives a hearing on the subject of salary increases for a a certain position and behold, there appears before the committee a number of engineers who state that even lower salaries than those paid at present are paid to engineers, and that engineers may be easily secured for the present salaries. What is a legislator to think?"

CENTRAL ELECTRIC STATIONS IN CANADA

EARLY this year announcement was made of the intention of the Dominion Bureau of Statistics to publish a volume of statistics obtained by a census of the central electric power stations in Canada. At the same time it was stated that the Dominion Water Power Branch, working in co-operation with the Dominion Bureau of Statistics, would publish a directory of the stations.

Both of these volumes are now ready for distribution. The census statistics, in French and English, fill a volume of about eighty pages, 6½ by 9¾ ins. The directory is a volume of 252 pages of the same size, and includes a large folded map showing the location of the stations.

For copies of the statistics volume, applications should be made to R. H. Coats, Dominion Statistician, Ottawa. For copies of the directory of central stations, applications should be made to J. B. Challies, Director of Water Power, Ottawa.

It was unanimously resolved at a meeting held in Toronto to discuss compulsory vaccination, that the provincial government be petitioned to enact legislation whereby sanitary engineers should be substituted for the present medical officers of health, and to make illegal the appointment to that office of any practitioner of any system of medicine.

PERSONALS

W. A. SIBBETT, of Bracebridge, Ont., has sailed for South America, where he has been employed by the Columbian government to survey the Barranquilla Harbor and to plan extensive water-front improvements. Mr. Sibbett was born November 4th, 1890, in Bracebridge, Ont., and was educated at Barrie Collegiate and the University of Toronto, where he graduated with honors in civil engineering with the class of 1911. He joined the staff of W. H. Fairchild, of Brantford, Ont., in order to study for the O.L.S. degree, and in 1912 he passed the necessary examinations. The following two years were spent with Mr. Fairchild in surveying and municipal work, and Mr. Sibbett was then appointed surveyor of the North Bay division of the C.P.R. In January, 1915, he joined a staff of engineers who were surveying harbors in British Columbia for the Dominion government, but in December, 1915, he resigned this position and enlisted as a private in the 122nd Muskoka Battalion, although he obtained a commission before he went overseas in April, 1917. While waiting to be sent overseas, Mr. Sibbett studied for the D.L.S. examinations, obtaining that degree in 1916. The military unit to which Mr. Sibbett was attached was sent directly from Canada to France, and there he was promoted to the rank of captain, and in April, 1918, he was transferred to the headquarters' engineering staff of the Canadian Forestry Corps. Last January he returned to Canada and obtained a provincial government survey contract for work in Northern Ontario, which contract he had just completed when he was recommended to, and accepted by, the Columbian government for the work above mentioned. Mr. Sibbett's present address is c/o Pinedo, Weeber & Co., Barranquilla, Colombia, South America.

GEORGE J. GUY, chairman of the Hamilton Harbor Commission, has been appointed vice-chairman of the Canadian Deep Waterways and Power Association.

HENRY HYMMEN, who has been water works superintendent of Kitchener, Ont., for the past 19 years, has resigned in order to take charge of the plant of the Dominion Products Co., Guelph, Ont.

J. CAMPBELL BRADY, of the British Columbia public works department, has been promoted to the rank of district engineer and will be in charge of No. 6 district, with jurisdiction over Cranbrook, Fernie and Columbia ridings.

LEWIE D. WALKER has been appointed water works engineer and inspector for the Canadian Fire Underwriters' Association, Toronto. Mr. Walker returned from overseas last March and joined the engineering staff of the British-American Nickel Corporation, at Deschenes, Que. Before going overseas he was employed at Sault Ste. Marie, Ont., in dock construction for the Department of Public Works of Canada.

W. BLAZER, civil engineer of the Government Service for Water Power and Electricity, Dutch East Indies, and whose headquarters are at Bandoeng, Java, is visiting Canada and the United States under a commission from the Netherlands' government to study water power stations. It is understood that the water power potentialities in the islands of the Dutch East Indies total several million horsepower. The government has developed and is operating several plants generating power for railway shops, etc., there are over three hundred private water power plants for plantations and other industries, and the government is pursuing an active development policy. Mr. Blazer intends also to visit Switzerland.

OBITUARY

JOHN DOBSON, for many years the senior member of the firm of Dobson & Jackson, contractors, Winnipeg, died in that city December 15th.

ROAD CONSTRUCTION IN BRITISH COLUMBIA

SPEAKING of the development of roads in British Columbia, J. Campbell Brady, a district engineer with the provincial public works department, said that the intention for the coming season is to improve and complete the road from Windermere to Cranbrook, making it come up to the standard of the Banff-Windermere highway, which the Dominion government recently took over and proposes to finish as an auto highway within the next two years. When these roads are completed, it will be possible to drive on a hard-surfaced road through Cranbrook to Spokane, via Yakh and Kingsgate.

From Golden to Windermere is approximately eighty miles, and most of this highway is in very fair condition. Twelve miles before Windermere is reached is the point at which the Banff-Windermere road converges. This road, which has only been partly developed by the provincial government and by the Canadian Pacific railway, now becomes a part of the Dominion government's park system.

A zone of five miles wide on each side of the highway has been set apart as a park area. At the Columbia, or Radium, hot springs, two miles from the junction of the Banff-Windermere highway with the road from Golden, there is every likelihood of a new tourist resort being established.

The annual meeting of the Ontario Good Roads Association will be held in Toronto March 3rd to 5th, 1920. The Ontario county roads superintendents will also convene at Toronto March 1st to 3rd.

In a speech at Brockville, Ont., Hon. F. C. Biggs, minister of public works for Ontario, dealt with the road system in that province. He said that the government hopes to add materially to it, and that instead of being 500 miles in length, the provincial highway should be 1,500 miles, touching every country. Unless this could be done to some extent, opposition to trunk roads will develop. He stated his belief that the provincial highway is the best advertising medium that Ontario has, and he strongly advocated further help from the government for the townships in road construction, and urged the appointment of permanent township road superintendents. Rural depopulation, said the minister, could be offset by good roads, improved rural schools, and the "Hydro."

Representing practically every municipality east of Kingston, a deputation waited on the Ontario government recently and requested that the Hydro-Electric Power Commission be instructed to proceed with the development of power at Chats Falls, Ont., and also with the development of the St. Lawrence river, in order that electric power may be furnished to industries which now wish to establish manufacturing plants in the eastern section of the province. W. E. Smallfield, chairman of the Utilities Commission of Renfrew, Ont., stated that 120,000 to 150,000 h.p. could be developed at Chats Falls, which is 30 miles from Ottawa, at a cost of from $5,000,000 to $8,000,000. This development, he claimed, could be undertaken at once, whereas it might take ten to fifteen years to get power from the St. Lawrence river.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Brampton, Ont.—Warren Bituminous Paving Co. of Ontario, Toronto, have contract for paving for town.

Edmonton, Alta.—Plans for a large, new suburban park on Big Lake, near here, include the construction of 10 miles of 30-ft. roadway. J. R. McIntosh is the promoter of the scheme.

Enderby, B.C.—Contract let by Provincial Department of Public Works to Robert Moncrieff, Kent Hotel, Victoria, for erection of $16,400 bridge.

Erickson, B.C.—Contract was not let by the Provincial Department of Public Works for the construction of a highway bridge over the Goat River, near Erickson, for which tenders closed November 25th, the department deciding to do the work by day labor.

Lac du Bonnet, Man.—Municipal council plans construction and improvement of public roads at cost of $50,000. Secretary-treasurer, W. D. Halliday.

Ontario County, Ont.—County council plans erection of several bridges. Road superintendent, R. R. Mowbray, Whitby, Ont.

Ottawa, Ont.—A by-law to have some 30 miles of county roads designated as provincial county highways was passed by Carleton county council.

Ottawa, Ont.—Carleton county council passed a resolution, asking the Department of Highways to construct the provincial county highway from Ottawa, via North Gower, to Ashton, where it will link up with the present county system of Lanark and run to Smith's Falls, via Prospect and Franktown. Lanark county council also recommended the construction of this highway, and it is expected the department will accede to the united request of the two counties.

Quebec, Que.—An important delegation called on Hon. J. A. Tessier, Minister of Roads, composed of representatives from the municipalities of Compton, asking for the construction of a regional route between Cookshire and Beecher Falls. The Minister promised to send an engineer next spring who would make a report on the matter.

Quebec, Que.—Three delegations, all interested in roads, recently called upon Hon. J. A. Tessier, Minister of Roads. The first delegation asked that the road from Laprairie to St. Johns and thence to Lacolle be completed as soon as possible. Another delegation was from the Eastern Townships, and mostly from Mississquoi, and were particularly interested in the proposed road from Lacolle to Knowlton. The third delegation urged the construction of the road on the North Shore, from St. Lambert to Levis. Hon. Mr. Tessier promised all the delegations he would give their request careful consideration.

Simcoe, Ont.—Plans will be prepared by Town Engineer G. R. Marston for erection of five bridges estimated to cost $70,000. By-law will be submitted.

South Hull, Que.—A movement is on foot by the municipal council of South Hull for the construction of a road to Aylmer. Secretary-treasurer, W. H. Stewart.

SEWER TENDER

The Essex Border Utilities Commission will receive proposals until 10 a.m., January 8th, 1920, for building the South Intercepting Sewer, which work includes the excavating for, laying, joining and backfilling approximately 8,483 feet of 27-in., 39-in. and 42in. reinforced concrete pipe now on the work, furnishing material for and building sixteen manholes, the cast-iron covers and steps for which are now on the work.

The work to be done on the basis of actual cost, plus a profit fee on a sliding scale, the lowest, capable, reliable bidder to receive a profit fee of 10% of the estimated cost of the work, this fee to be increased by 25% of any amount by which the actual cost is less than the estimated cost submitted by the contractor, and to be decreased by 10% of any amount by which the actual cost exceeds the contractor's estimated cost.

Each proposal to be accompanied by a certified cheque for $1,000 as a guarantee that in case proposal is accepted the bidder will enter into the contract and furnish bond in form approved by solicitor of Commission that he will complete the work within the time specified and in a manner acceptable to the Commission and protect the Commission against all liabilities.

Plans and specifications of the work are on file at the office of the Commission, 66 Ouellette Avenue, Windsor, Ont., and may be secured on depositing $25,00, which deposit will be refunded in case they are returned in good condition on or before January 15th, 1920. The right is reserved to reject any or all proposals or to accept the one that is for the best interests of the District.

ESSEX BORDER UTILITIES COMMISSION.
GORDON M. McGREGOR, Chairman.
394 W. J. BAXTER, Secretary.

St. Jean de Matha, Que.—Town council will gravel part of the Joliette-St. Emelie Rd. at a cost of $6,255. Secretary, J. O. Leveille.

Sumas, B.C.—Fire damaged the low-trestle bridge over Matsqui prairie, near here, to the extent of $2,000 or $3,000.

Tillsonburg, Ont.—By-law re construction of pavement will be submitted. Town clerk, A. E. Raynes.

Toronto, Ont.—Work will start next spring on the construction of a new roadway in Earlscourt district.

Walkerton, Ont.—Town council plans construction of pavement. Clerk, A. Collins.

Whitby, Ont.—Ontario county council let contract to P. J. Kehoe at $2,125 for rebuilding Scott's Creek bridge.

Whitby, Ont.—Ontario county council plans road improvements and purchase of stone-crushing equipment.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Works, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Tuesday, December 30th, 1919, for supply of a small batch concrete mixer having a capacity of from 6 to 7 cubic feet per batch. Specification may be obtained at the office of the City Engineer, 223 James Ave.

WATER, SEWAGE AND REFUSE

Brantford, Ont.—Final report on reconstruction of waterworks has been submitted to city council by R. S. and W. S. Lea, engineers, Montreal.

Chatham, Ont.—A by-law will be submitted to the electors in January to decide which waterworks scheme they are in favor of adopting, the Thames River filtration scheme, or the Lake Erie scheme.

Moncton, N.B.—City council let contract to Louis Stephens and Co. for the completion of the main sewer in Block 9.

Moncton, N.B.—City council plans extension of water main from Irishtown Crossing to the new pumping station. City engineer, J. Edington.

Moncton, N.B.—City council let contract for valves to T. McAvity and Sons, Ltd., St. John, N.B., and for 18-inch pipe, necessary to connect the old and new water systems, to the Sumner Co.

Richmond, B.C.—Three schemes for new drainage are being considered by municipal council. Clerk, S. Shepherd.

Richmond, Que.—Tenders addressed to A. V. Glassey, secretary-treasurer, Richmond, Que., will be received up to 12 o'clock noon on Wednesday, December 31st, 1919, for the construction of sewer and water line. Plans and specifications may be seen on application at the town office.

Stratford, Ont.—City council will have a sanitary sewer constructed on the east side of Trinity St. City engineer, A. B. Manson.

Timmins, Ont.—The question of installing a chlorination plant will be taken up by next year's council. Clerk, H. E. Montgomery.

Toronto, Ont.—City council plans to purchase belt conveyer for main sewage disposal station.

Walkerville, Ont.—Contract for the laying of 1,600 feet of sewer on Kildare Rd. awarded by town council to Merlo, Merlo and Ray at $9 a foot. The sewer will lead from the Essex Terminal Ry. to the Tecumseh Rd. It will be of 30-inch concrete pipe.

Winnipeg, Man.—The Manitoba Drainage Commission will take up the question of adopting a system to drain 300,000 acres of land in the southern part of the province at a meeting to be called soon after the New Year. Chairman, J. G. Sullivan, Winnipeg.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Works, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Tuesday, December 30th, 1919, for the construction of a sewer in Pritchard Ave., from Prince St. eastward to the C.P.R Selkirk branch. Specification may be obtained at the office of the City Engineer, 223 James Ave.

Woodstock, Ont.—By-law to provide $100,000 for construction of an intercepting trunk sewer and sewage disposal plant will be submitted to electors at municipal elections. City clerk, John Morrison.

LIGHT, HEAT AND POWER

Belleville, Ont.—City council will take up with the Hydro-Electric Power Commission of Ontario the question of developing further power in this district from Ranney's Falls.

Elk Lake, Ont.—It is stated that a scheme of power development at Indian Chutes, on the Montreal River, a short distance north of Elk Lake, is projected, and that power will be available by the fall of 1920. It is said that between 4,000 and 5,000 h.p. can be developed.

Galt, Ont.—By-law to raise $30,000 for installing a central heating plant for the Galt General Hospital, the Isolation Hospital, the Maternity Hospital and the new Nurses' Home, and for building an addition to the present laundry and heating plant of the Galt Hospital, will be submitted at municipal elections. Clerk, Joseph McCartney.

Lakefield, Ont.—By-law to authorize the installation of a Hydro-Electric system will be submitted to electors at January election. The total cost of installing the system, which includes the reconstruction of the present distribution plant and its purchase from the local electric light company, etc., is $33,500.

Marmora, Ont.—Town council plans to construct new sub-station and Hydro power distribution system to cost $14,000. By-law may be submitted. Clerk, H. W. Sabine.

Regina, Sask.—The construction of a high transmission power wire from the Regina power plant to Lumsden, Sask., is projected. Address, W. J. Vancise, Lumsden.

Stratford, Ont.—City council passed by-law for the issuing of debentures for extension to the local power station. City clerk, R. R. Lang.

Tara, Ont.—Town council plans extension to Hydro system. Clerk, W. J. Taylor.

Toronto, Ont.—Deputations from municipalities east of Kingston waited upon the Ontario Cabinet, asking that the Hydro-Electric Power Commission of Ontario be instructed to proceed with the development of power at Shaw Falls and the St. Lawrence River; and further, that they be given representation on the Hydro Commission, naming Mayor Lewis, of Brockville. It was stated that approximately 150,000 h.p. could be developed at Shaw Falls, about 30 miles from Ottawa, at a cost of from five to eight million dollars.

Toronto, Ont.—Permission was given the Civic Hydro Commission by the city council to apply to the Ontario Railway Board for authority to raise another $950,000 to provide for needed extensions of the system.

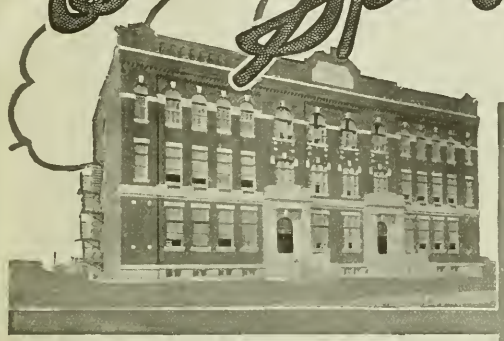
Waterloo, Ont.—The Waterloo Water and Light Commission decided to place an order at once for transformers and other equipment in order to increase the capacity of the plant from 1,200 to 3,000 h.p.

Winnipeg, Man.—Contract for aluminum transmission cables needed for extension of city's power transmission line has been let to the Northern Aluminium Co., Ltd., the amount of contract being approximately $250,000.

Winnipeg, Man.—Contracts have been let for two 5,000-h.p. transformers for installation in the Point du Bois power plant, one to the Canadian General Electric Co. for $33,000 and the other to the Canadian Westinghouse Co. for $35,553.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Works, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Tuesday, December 30th, 1919, for the supply of 200 lengths of 1½ in. by 14 ft. boiler tubes for steam rollers. Specification may be obtained at the office of the City Engineer, 223 James Ave.

Barrett Specification Roofs



20-Year Barrett Specification Roof on St. Marc's School, Montreal. Owners: Catholic School Board, Montreal. Architects: Vautrin & Bernier, Montreal. Gen. Cont.: Ulric Boileau, Limited, Montreal. Roofers: Canada Roofing & Paving Company, Montreal.

20-Year Barrett Specification Roof on Old Orchard Avenue School, at Notre Dame de Grace. Owners: School Commissioners of Notre Dame de Grace, Montreal. Architects: Audet & Charbonneau, Montreal Roofers: Tremblay & Francoeur, Montreal.

The *modern* way to buy a roof—

When the two school buildings shown above were completed, we handed their owners, the Catholic School Board of Montreal, Surety Bonds which *guarantee* the roofs against trouble or maintenance expense for a period of *20 years*.

The probabilities are that these roofs will last for nearer *30 years* without attention.

This is the *modern* way of buying a roof, not merely purchasing so many square feet of roof at so much per square foot, but investing in a long and definite period of *guaranteed service*.

The Barrett Specification first made it possible for building owners everywhere to obtain, through their local contractors, *a standardized roof* built according to the most scientific principles of roof construction.

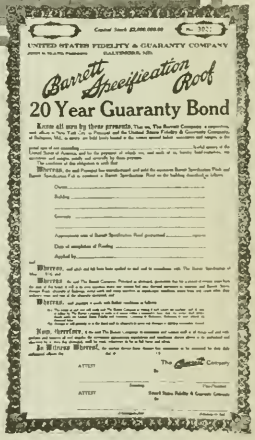
Guarantee 20 Years of Service

Now we offer to go a step further and actually *guarantee* a Barrett Specification Roof *for a period of at least 20 years!*

This guarantee, obtainable on any roof of 50 squares or more, in any town of 25,000 or over, and in smaller places where our Inspection Service is available, is in the form of a Surety Bond, issued by a well-known fidelity company.

To obtain the Bond you have only to insert in your building specifications the following:

"The roof shall be laid according to The Barrett Specification dated May 1, 1916, and the roofing contractor shall secure for me (or us) the 20-Year Guaranty Bond therein mentioned."



UNITED STATES FIDELITY & GUARANTY COMPANY

Barrett Specification Roof

20 Year Guaranty Bond

This is the bond that guarantees your roof for twenty years.

The guarantee costs you nothing. We merely require an opportunity to send our Inspectors to watch the job during construction.

You get a roof that will cost less per year of service than any other type of permanent roof, and that takes the base rate of insurance. We get the satisfaction of knowing that our materials are creditably used.

We should be very glad to send you further details and copy of the Barrett 20-Year Specification, with diagrams, ready for insertion in your building plans.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Winnipeg, Man.—Four tenders have been received for the water turbines needed for the extension to the city's power plant at Point du Bois, these tenders being from the Boving Hydraulic and Engineering Co., Ltd., Canadian Allis-Chalmers Co., Ltd., S. Morgan Smith Co. and Vickers, Ltd. The amounts of these tenders are understood to be in the neighborhood of $200,000.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, December 29th, 1919, for the supply of three 200 k.w. single-phase outside transformers, delivered, f.o.b. cars, Winnipeg, freight and duty paid. Specification may be obtained at the office of the City Light and Power Department, 54 King St.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, December 29th, 1919, for the supply of 1,200 feet of 250,000 G.M. 13,500-volt, 3-core, lead-covered, paper-insulated cable, delivered, f.o.b. cars James St. yard, Winnipeg, freight and duty paid. Specification may be obtained at the office of the City Light and Power Department, 54 King St.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, January 12th, 1920, for the supply and delivery at the power house, Point du Bois, Manitoba, and terminal station, Winnipeg, of a quantity of electrically operated oil switches and switching apparatus. Specification may be obtained at the office of the City Light and Power Department, 54 King St.

Winnipeg, Man.—Tenders addressed to the chairman, Committee on Fire, Water, Light and Power, will be received at the office of C. J. Brown, city clerk, up to 3 o'clock p.m. on Monday, January 26th, 1920, for the supply, delivery and erection on foundations supplied by the corporation in its power house, Point du Bois, of two 3-phase generators for direct connection to double reaction turbines, and for spare parts for same; also for one additional or extension set, ordered, furnished and installed under the same conditions. Specification may be obtained at the office of the City Light and Power Department, 54 King St.

RAILWAYS

Calgary, Alta.—Three plans for the extension of the street railway in North Balmoral and Tuxedo Park are under consideration by city council. The costs of the schemes vary from $14,000 to $20,000 each. City clerk, J. M. Miller.

Darlington Tp., Ont.—Electors endorsed the by-law to guarantee the bonds of the proposed Toronto and Eastern radial. Only Toronto and York township have still to vote on the project. All the other municipalities between Toronto and Bowmanville have voted in favor of the radial.

Hamilton, Ont.—It has been announced that construction work on the Hamilton-Guelph-Elmira Hydro radial line will start next spring, and that the line will be completed and in operation in 1921.

Mount Laurier, Que.—Quebec Colonization Ry. Co. plans construction of new line from Mount Laurier south-west to C.P.R. at or near Maniwaki, and is applying for provincial charter. Attorneys, Dessaulles, Garneau, Desy and Lorrain 86 Notre Dame St. West, Montreal.

New Liskeard, Ont.—Nipissing Central Ry. Co., care of T. and N.O. Ry. Commission, 56 Church St., Toronto, plans construction of railway line from New Liskeard to North Temiskaming, a distance of 17 miles. Chief engineer, S. B. Clement, North Bay.

Quebec, Que.—Board of Trade will urge Federal government to study the practicability of the establishment of a railroad from Quebec to St. Stephen, N.B.

Quebec, Que.—Extension and improvements to street railways planned by Quebec Railway, Light, Heat and Power Co., 229 St. Joseph St.

Regina, Sask.—The addition of another unit to the car barns and a second story on the office building is included in the proposed Regina Street Railway improvements for 1920. The double-tracking of at least a portion of Fifth Ave. is also planned.

Regina, Sask.—A project to extend the street car lines next spring is being considered. City commissioner, L. A. Thornton.

Sarnia, Ont.—Sarnia will shortly commence negotiations to purchase the now privately owned Sarnia street railway system.

Swift Current, Sask.—Deputations from the Swift Current district recently interviewed D. C. Coleman, vice-president and general manager of the C.P.R. at Regina, requesting the construction of a railway line from Dunelm, on the Vanguard branch, to Instow, on the Weyburn-Lethbridge line; also a line through the Vermilion Hills from Swift Current to a point near Moose Jaw.

Winnipeg, Man.—The Canadian Pacific Ry. have made preliminary arrangements for building a railway line into The Pas district, which would ultimately mean the erection of a railway by that concern into the Copper Lake and Lake Athapupouskou gold district.

York Tp., Ont—On January 17th, 1920, the ratepayers will vote on the by-law for the construction of the new radial line from Toronto to Bowmanville. The total cost of the new radial, it is estimated, will be $8,360,794, and the amount to be borne by York township is $381,587.

FACTORIES AND LARGE BUILDINGS

Aurora, Ont.—G.W.V.A. plan erection of clubhouse.

Bagot, Man.—Tenders will be received up to January 1st, 1920, for remodelling Hartford School (S.D. No. 896), 4½ miles south of Bagot. Plans and specifications may be secured by applying to Geo. Richards, secretary, Bagot P.O., Man.

Bowmanville, Ont.—G.W.V.A. plan clubhouse. Address, Alderman Fisher.

Brampton, Ont.—Contract let to Blatz Bros., 187 Charlton Ave East, Hamilton, for building costing $25,000 for Universal Batteries, Ltd.

Calgary, Alta.—Hon. Geo. P. Smith, Provincial Minister of Education, announced that the preliminary draft of the plans in connection with the new Technical Institute to be erected here is nearly completed. It is anticipated that good progress will be made with the building next spring.

Cap de la Madeleine, Que.—J. A. Rousseau, Ste. Anne de la Perade, plans erection of sawmill. Estimated cost, $100,000.

Chatham, Ont.—Dominion Department Public Works plans extension to post-office. Secretary, R. C. Desrochers, Ottawa.

Dartmouth, N.S.—Work will start at once on erection of rink for the Red Sox A.A.A.

Drummondville, Que.—School building destroyed by fire.

Dundas, Ont.—Canada Crushed Stone Corporation will rebuild roundhouse destroyed by fire. Secretary-treasurer, J. B. Harte.

Flaxcombe, Sask.—Contract let to R. N. Wyatt, Winnipeg, for bank costing $6,000 for Merchants Bank of Canada

Fredericton, N.B.—Members of Christ Church Cathedral plan erection of a Memorial Hall and Chapter House on Church St.

Galt, Ont.—Galt Knitting Co. plans erection of new office building. Work will start in spring.

Gananoque, Ont.—Gananoque Canoe and Motorboat Club plan addition to clubhouse.

Glace Bay, N.S.—The erection of a $30,000 rink is projected here.

Goulburn Tp., Ont.—By-law to borrow $7,000 for the purchase of site and erection of town hall will be submitted to electors at municipal elections. Clerk, J. A. Cummings, Stittsville, Ont.

Guelph, Ont.—The value of building permits issued during the month of November reached $20,325. This brings the total for the year, up to the end of last month, to $599,144, the best year Guelph has had for some time.

Halifax, N.S.—The warehouse building of the Maritime Telephone and Telegraph Co. was damaged by fire to extent of from $100,000 to $150,000.

Hamilton, Ont.—The erection of an office building on Main St. East is planned by Doctors Mowbray and McGregor.

Holdfast, Sask.—Members of Roman Catholic Church plan erection next spring of new church at cost of $35,000. Address, Rev. B. Ueberberg.

Hull, Que.—Dominion Fertilizer Co. will erect a factory in West Hull.

Indian Head, Sask.—Orangemen plan erection of Orphanage.

Irvine, Alta.—The brick schoolhouse at Irvine has been totally destroyed by fire.

New Glasgow, N.S.—The Nova Scotia Steel and Coal Co. has acquired for $2,000,000 a controlling interest in the

Everything for all Engineers

Any one of these standard books makes an unequaled New Year's gift. Think of the feeling of intense satisfaction *you* would experience on receiving a valuable present which could be used with profit every day, not only for a short time, but for years to come! Then, buy one of these books for some friend who will welcome it.

A Brand New Edition!

American Civil Engineers' Handbook

4th Edition, Extensively Revised and Enlarged. MANSFIELD MERRIMAN, Editor-in-Chief, and 18 Associate Editors.

The pre-eminent Handbook for civil engineers. In addition to two new sections on important subjects (Electric Railroads, and Irrigation and Drainage), the others have been revised—in some cases practically rewritten—and brought up to date. Now, more than ever before, this is the standard book for the practicing civil engineer.

1959 pages. 4¼ by 7. Fully illustrated. Flexible binding, $6.00 net. (Ready February 20, 1920.)

American Highway Engineers' Handbook

ARTHUR H. BLANCHARD, Editor-in-Chief, and 17 Associate Editors.

"So complete in the broad and comprehensive way in which it discusses all questions relating to modern highway matters that it should prove a valuable reference book to any of those engaged in this line of work," said one reviewer. He's right, it is.

xxv+1658 pages. 4¼ by 7. Illustrated. Flexible binding, $6.00 net.

Handbook for Electrical Engineers

HAROLD PENDER, Editor-in-Chief, and a Staff of Specialists.

A Handbook of electrical facts covering every field of electrical engineering, and offering data which would ordinarily be accessible only through an extensive reference library.

xxviii+2023 pages. 4¼ by 7. Illustrated. Flexible binding, $6.00 net.

Kidder's Architects' and Builders' Pocket Book

16th Edition, Revised and Enlarged. THOMAS NOLAN, Editor-in-Chief, and a Staff of Specialists.

Contains in condensed form the knowledge and experience of a score of experts in every phase of building design and construction.

xxiii+1816 pages. 4¼ by 7. Illustrated. Flexible binding, $6.00 net.

Mechanical Engineers' Pocket Book

9th Edition, Revised. By the late WILLIAM KENT, D.Sc., with the Assistance of ROBERT THURSTON KENT, M.E.

Covers the entire field of mechanical engineering, presenting the information that the engineer needs in his daily work, in condensed, usable form.

xlvi–1526 pages. 4¼ by 7. Illustrated. Flexible binding $6.00 net.

Mining Engineers' Handbook

ROBERT PEELE, Editor-in-Chief, and 43 Associate Editors.

For mining engineers generally, and also for those whose interest is in the construction details involved in the installation of plant.

x+2375 pages. 4¼ by 7. 2000 figures. Flexible binding $6.00 net.
